Z_c(3900): Confronting theory and lattice simulations

Miguel Albaladejo, Juan Nieves, and Pedro Fernandez-Soler
Instituto de Física Corpuscular (IFIC, Centro Mixto CSIC-Universidad de Valencia, Instituto de Investigación de Paterna, Aptdo. 22085, E-46071 Valencia, Spain

We consider a recent T-matrix analysis by Albaladejo et al., [Phys. Lett. B 755, 337 (2016)] which accounts for the J/ψρ and D̄D coupled-channels dynamics, and that successfully describes the experimental information concerning the recently discovered Z_c(3900)⁺. Within such scheme, the data can be similarly well described in two different scenarios, where the Z_c(3900) is either a resonance or a virtual state. To shed light into the nature of this state, we apply this formalism in a finite box with the aim of comparing with recent Lattice QCD (LQCD) simulations. We see that the energy levels obtained for both scenarios agree well with those obtained in the single-volume LQCD simulation reported in Prelovšek et al. [Phys. Rev. D 91, 014504 (2015)], making thus difficult to disentangle between both possibilities. We also study the volume dependence of the energy levels obtained with our formalism, and suggest that LQCD simulations performed at several volumes could help in discerning the actual nature of the intriguing Z_c(3900) state.

I. INTRODUCTION

Since the discovery of the X(3872) in 2003 [1], the charmonium and charmonium-like spectrum are being continuously enlarged with new so-called XYZ states [2–4], many of which do not fit properly in the conventional quark models [5]. The relevance of meson-meson channels can be grasped from the fact that all the charmonium states predicted below the lowest hidden-charm threshold (D̄D) have been experimentally confirmed, but above this energy most of the observed states cannot be unambiguously identified with any of the predicted charmonium c̄c states.

Amongst the XYZ states, the Z_c(3900)⁺ was simultaneously discovered by the BESIII and Belle collaborations [6, 7] in the e⁺e⁻ → Y(4260) → J/ψπ⁺π⁻ reaction, where a clear peak very close to the D̄D threshold, around 3.9 GeV, is seen in the J/ψπ spectrum. Later on, an analysis [8] based on CLEO-c data for a different reaction, e⁺e⁻ → ψ(4160) → J/ψπ⁺π⁻, confirmed the presence of this resonant structure as well, although with a somewhat lower mass. The BESIII collaboration [9, 10] has also reported a resonant-like structure in the D̄D spectrum for the reaction e⁺e⁻ → D̄D∗D̄ at different e⁺e⁻ center-of-mass (c.m.) energies [including the production of Y(4260)]. This structure, with quantum numbers favored to be J(P) = 1⁺, has been cautiously called Z_c(3885)⁺, because its fitted mass and width showed some differences with those attributed to the Z_c(3900)⁺. Whether both set of observations correspond to the same state needs to be confirmed, though there is a certain consensus that this is indeed the case, and the peaks reported as the Z_c(3885)⁺ and Z_c(3900)⁺ are originated by the same state seen in different channels. Moreover, evidence for its neutral partner, Z_c(3900)⁰, has also been reported [8, 11].

The nature of the Z_c(3900)⁺ is intriguing. On one hand, it couples to D̄D∗ and J/ψπ, and therefore one assumes it should contain a constituent c̄c quark–anti-quark pair. On the other hand, it has charge and hence it must also have another constituent quark–anti-quark pair, namely ud (for Z_c⁺). Its minimal structure would be then c̄cud, which automatically qualifies it as a non-qq̄ (exotic) meson. Being a candidate for an exotic hidden charm state, it has triggered much theoretical interest. An early discussion of possible structures for the Z_c(3900)⁺ was given in Ref. [12]. The suggested interpretations cover a wide range: a D̄D molecule [13–20], a tetraquark [21–27], an object originated from an attractive D̄D∗ interaction [28], a simple kinematical effect [29, 30], a cusp enhancement due to a triangle singularity [31], or a radially excited axial meson [32]. In Ref. [35], it was argued that this structure cannot be a kinematical effect and that it must necessarily be originated from a nearby pole. Consequences from some of these models have been discussed in Ref. [34]. The non-compatibility (partial or total) of the properties of the Z_c deduced in different approaches clearly hints why the actual nature of this state has attracted so much attention.

In Ref. [35], theoretical basis of the present manuscript, a J/ψπ–D̄D coupled-channels scheme was proposed to describe the observed peaks associated to the Z_c(3900), which is assumed to have I(JPC) = 1(1++) quantum numbers.¹ Within this coupled channel scheme, it was possible to successfully describe simultaneously the BESIII J/ψπ [6] and D̄D∗ [10] invariant mass spectra, in which the Z_c(3900)⁺ structure has been seen. Interestingly, two different fits with similar quality were able to reproduce the data. In each of them, the origin of the Z_c(3900)⁺ was different. In the first scenario, it corresponded to a resonance originated from a pole above the D̄D threshold, whereas in the second one the structure was produced by a virtual pole below the threshold (see Ref. [35] for more details).

¹ Through all this work, charge conjugation refers only to the neutral element of the Z_c(3900) isos triplet.
gies of that system in an infinite volume. Appropriate generalizations relevant for our work can be found in Refs. [43–46].

LQCD simulations devoted to find the \( Z_c(3900) \) state are still scarce [47–52]. Exploratory theoretical studies for hidden charm molecules have been performed in Refs. [53, 54], while actual LQCD simulations [47–51] find energy levels showing a weak interaction in the \( Z_c(3900)^\pm \) quantum-numbers sector (either attractive or repulsive), and no evidence is found for its existence. The work of Ref. [52] employs LQCD to obtain a coupled-channel S-matrix, which shows an interaction dominated by off-diagonal terms, and, according to Ref. [52], this does not support a usual resonance picture for the \( Z_c(3900) \). This S-matrix contains a pole located well below threshold in an unphysical Riemann sheet, i.e., a virtual pole. It is worth to note that this possibility could be in agreement with the second scenario advocated in Ref. [35], and mentioned above.

Our objective in the present manuscript is to implement the coupled channel T-matrix fitted to data in Ref. [35] in a finite volume and study its spectrum. Thus, we will be able to compare the energy levels obtained with this finite volume T-matrix with those obtained in LQCD simulations, in particular those reported in Ref. [48]. This work is organized as follows. The formalism is presented in Sec. II, while the T-matrix of Ref. [35] is briefly discussed in Subsec. II A, and its extension for a finite volume is outlined in Subsec. II B. Results are presented and discussed in Sec. III, and the conclusions of this work, together with a brief summary are given in Sec. IV.

II. FORMALISM

A. Infinite volume

We first briefly review the model of Ref. [35] (where the reader is referred for more details) that we are going to employ here. There, the \( Y(4260) \) decays to \( D\bar{D}^* \) and \( J/\psi \pi \) are studied with a model shown diagrammatically in Fig. 1 of that reference. Final state interactions among the outgoing \( D\bar{D}^* \) and \( J/\psi \pi \) produce the peaks observed by the BESIII collaboration, which are associated to the \( Z_c(3900) \) state. The two channels involved in the \( 1^{+}\) T-matrix are denoted as \( 1 = J/\psi \pi \) and \( 2 = D\bar{D}^* \). Solving the on-shell version of the factorized Bethe-Salpeter equation (BSE) allows to write:

\[
T^{-1}(E) = V^{-1}(E) - G(E),
\]

where \( E \) is the c.m. energy of the system. The symmetric V matrix is the potential kernel, whose matrix elements have the following form:

\[
V_{ij} = 4\sqrt{m_{i1}m_{i2}m_{j1}m_{j2}} C_{ij} e^{-k^2 i / \Lambda_i^2} e^{-k^2 j / \Lambda_j^2},
\]

with \( m_{i1} \) and \( m_{j2} \) the masses of the particles of the \( i \)th channel and \( k^2 \), the relative three-momenta squared in the c.m. frame, implicitly defined through:

\[
E = \omega_\phi(k_1) + \omega_\pi(k_1),
\]

\[
E = \omega_{D\bar{D}}(k_2),
\]

where:

\[
\omega_\phi(q) = \sqrt{m_{\phi}^2 + q^2},
\]

\[
\omega_\pi(q) = \sqrt{m_{\pi}^2 + q^2},
\]

\[
\omega_{D\bar{D}}(q) = m_D + m_{\pi} + \frac{m_D + m_{D'}}{2m_Dm_{D'}} q^2.
\]

with \( q \equiv |q| \). The Gaussian form factors \( e^{-k^2 i / \Lambda_i^2} \) are introduced to regularize the BSE, and thus, for each channel, an ultraviolet (UV) cut-off \( \Lambda_i \) is introduced. In this work, we have used \( \Lambda_1 = 1.5 \text{ GeV} \) and two values for \( \Lambda_2 = 0.5 \) and 1 GeV [55, 56]. The \( C_{ij} \) matrix stands for the S-wave interaction in the coupled-channels space, and it is given by [35]:

\[
C = \begin{bmatrix} 0 & \tilde{C} \\ \tilde{C}^\dagger & C_{22}(E) \end{bmatrix}.
\]

In Eq. (8) the \( J/\psi \pi \to J/\psi \pi \) interaction is neglected, \( C_{11} = 0 \), the inelastic transition one is approximated by a constant, \( \tilde{C} \), while the \( D\bar{D}' \to D\bar{D}' \) potential \( C_{22}(E) \) is parametrized as:

\[
C_{22}(E) = C_{12} + b (E - m_D - m_{D'}).
\]

In a momentum expansion, the lowest order contact potential for this elastic transition would be simply a constant, \( C_{22} \equiv C_{12} \). However, it is easy to prove that two coupled channels with contact potentials cannot generate a resonance above threshold. Thus and for the sake of generality, the model of Ref. [35] allows for an energy dependence in Eq. (9), driven by the \( b \) parameter. The G matrix in Eq. (1) is diagonal, and its matrix elements are the \( J/\psi \pi \) and \( D\bar{D}' \) loop functions:

\[
G_{11}(E) = \int_{\mathbb{R}^3} \frac{d^3q}{(2\pi)^3} \frac{\omega_\phi(q) + \omega_\pi(q)}{2\omega_\phi(q)\omega_\pi(q)\omega(E) - \left(\omega_\phi(q) + \omega_\pi(q)\right)^2 + i\epsilon} e^{-2(q^2 - k^2 i) / \Lambda_i^2},
\]

\[
G_{22}(E) = \frac{1}{4m_Dm_{D'}} \int_{\mathbb{R}^3} \frac{d^3q}{(2\pi)^3} \frac{e^{-2(q^2 - k^2 i) / \Lambda_i^2}}{E - \omega_{D\bar{D}}(q) + i\epsilon},
\]

which account for the right-hand cut of the T-matrix, that satisfies in this way the optical theorem. The \( D\bar{D}' \) channel loop function \( G_{22} \) is computed in the non-relativistic approximation.

The free parameters in the interaction matrix \( C \) (\( \tilde{C} \), \( C_{12} \) and \( b \)) were fitted in Ref. [35] to the experimental \( J/\psi \pi^- \) and \( D^+D^{*-} \) invariant mass distributions in the \( Y(4260) \to J/\psi \pi \) and \( Y(4260) \to D\bar{D}' \) decays [6, 10]. The fitted parameters are compiled here in Table I, where we can see the two different scenarios investigated in Ref. [35]. In the first one, \( b \neq 0 \), the \( Z_c \) appears as a \( D^* \bar{D} \) resonance, i.e., a pole above the \( D^* \bar{D} \) threshold in a Riemann sheet connected with the physical one above this energy. In the second one, where \( b = 0 \), a pole appeared below the \( D\bar{D}' \) threshold in an unphysical Riemann sheet, which gives rise to the \( Z_c(3900) \) structure, peaking exactly at the \( D\bar{D}' \) threshold in this case [35] (see also Ref. [57]).
Finally, the discrete, interacting energy levels reported in Ref. \[8\], together with the \(Z\) pole positions found in that work. The errors account for statistical (first) and systematic (second) uncertainties (see Ref. \[35\] for details).

| \(\Lambda_2\) (GeV) | \(C_{12}\) (fm\(^2\)) | \(b\) (fm\(^3\)) | \(\bar{C}\) (fm\(^2\)) | \(M_1\) (MeV) | \(\Gamma_{12}/2\) (MeV) |

### B. Finite volume

In this subsection, we study the previous coupled channel \(T\)-matrix in a finite volume. The consequence of putting the interaction in a box of size \(L\) with periodic boundary conditions is that the three-momentum is no longer a continuous variable, but a discrete one. For each value of \(L\), we have the infinite set of momenta \(\vec{q} = \frac{2\pi}{L}\vec{n}, \vec{n} \in \mathbb{Z}^3\). The integrals in Eqs. (10) and (11) will be replaced by sums over all the possible values of \(\vec{q}\):

\[
\tilde{G}_{11}(E) = \frac{1}{L^3} \sum_{\vec{n}} \frac{\omega_\phi(q) + \omega_\pi(q)}{2\omega_\phi(q)\omega_\pi(q)} e^{-2(q^2 - i\vec{q} \cdot \vec{n})/\Lambda_2^2} E^2 - \left(\omega_\phi(q) + \omega_\pi(q)\right)^2,
\]

\[
\tilde{G}_{22}(E) = \frac{1}{4(m_Dm_{D^*})} \frac{1}{L^3} \sum_{\vec{n}} e^{-2(q^2 - i\vec{q} \cdot \vec{n})/\Lambda_2^2} E - \omega_{D^*D}(q),
\]

(see Ref. \[53\] for further details). The \(T\)-matrix in a finite volume is then:

\[
\tilde{T}^{-1}(E) = V^{-1}(E) - \tilde{G}(E),
\]

where the \(\tilde{G}\) matrix elements are given by Eqs. (12) and (13). The discrete energy levels in the finite box are given by the poles of the \(\tilde{T}\)-matrix. If the interaction is switched off, \(V \to 0\), the free (or non-interacting) energy levels are given by the poles of the \(\tilde{G}\) functions,

\[
E_{J/\psi\pi}^{(D)} = \omega_\phi(q_Ln) + \omega_\pi(q_Ln), \quad (15)
\]

\[
E_{D^*D}^{(D^*)} = \omega_{D^*D}(q_Ln), \quad (16)
\]

where we use the shorthand \(q_L = 2\pi/L\), and \(n = \sqrt{n^2}\). The effect of the interaction is to shift these non-interacting energy levels.

Our purpose is to make contact with the results reported in the LQCD simulation of Ref. \[48\], and hence we will employ the masses and the energy-momentum dispersion relations used in that work. For the \(J/\psi\pi\) channel the dispersion relation in Eq. (3) is still appropriate, but for the case of the \(D^*D\) channel, in Eqs. (4) and (7), \(\omega_{D^*D}(q)\) must be replaced by \[48, 58\]:

\[
\omega_{D^*D}(q) = m_{D,1} + m_{D^*,1} + \frac{m_{D,2} + m_{D^*,2}}{2m_{D,2}} q^2 - \frac{m_{D,4} + m_{D^*,4}}{8m_{D,4}m_{D^*,4}} q^4. \quad (17)
\]

This lattice energy of the \(D^*D\) pair suffers from discretization errors and it must be used in Eq. (13). The non-interacting energy levels in Eq. (16) should be also modified accordingly. Notice that, because of the factor \(e^{-q^2/\Lambda_2^2}\), the sum in Eq. (13) is exponentially suppressed in \(\vec{n}^2\). For the range of energies considered in this work, it is sufficient to add terms up to \(\vec{n}^2 = 6\).\(^2\) Finally, the discrete, interacting energy levels reported in Ref. \[48\] are actually the result of applying the following shift:

\[
E \to E^* = E - m_{s,a}^{\text{lat}} + m_{s,a}^{\text{exp}},
\]

where the spin-average mass \(m_{s,a}\) is given by \(m_{s,a} = \frac{1}{2}(m_{\eta_c} + 3m_{J/\psi})\). For this reason, we will also present our energy levels shifted as in Eq. (18). The parameters involved in our calculations, taken from Refs. \[48, 58\], are collected in Table II. In particular, one has \(m_{s,a} = 266 \pm 4\) MeV and \(L = 16a = 1.98 \pm 0.02\) fm, being \(a\) the lattice spacing.

### C. Further comments

With all the ingredients presented in Subsec. II B, we can compare our predictions for the energy levels in a box with those reported in Ref. \[48\]. But before presenting our results

\(^2\) We have checked that the numerical differences are negligible if larger values, say \(\vec{n}^2 = 8\), are used.
we would like to discuss some technical details concerning two differences that could affect the comparison.

First, we would like to note that the LQCD simulation in Ref. [48] includes the $J/\psi\pi$ and $D^*\bar{D}$ channels that are present in our $T$-matrix analysis, but it also includes other channels (like $\eta,\rho$ or $D^*\bar{D}^*$). However, according to Ref. [35], it is sufficient to include the $J/\psi\pi$ and $D^*\bar{D}$ channels to achieve a good reproduction of the experimental information concerning the $Z_c(3900)$. For this reason, we expect that, in first approximation, these other channels could be safely neglected in the calculations.

The second point to be noted is that we are ignoring the possible $m_\pi$ dependence of the parameters in the potential, Eq. (8). Nonetheless, the LQCD simulation of Ref. [48] is performed for a relatively low pion mass, $m_\pi = 266 \pm 4$ MeV, and we thus expect the eventual dependence to be mild. Furthermore, we are going to compare several sets of these parameters (presented in Table I), which somewhat compensates this effect.

### III. RESULTS AND DISCUSSION

In Fig. 1, we show the $L$ dependence of some energy levels close to the $D^*\bar{D}$ threshold. They have been computed from the poles of the finite volume $T$-matrix, Eq. (14), by using the parameters of Table I for $\Lambda_2 = 1$ GeV, and the lattice setup given in Table II. The levels obtained in the $Z_c(3900)^*$ resonance (virtual) scenario, calculated using the entries of the first (third) row of Table I, are displayed in the left (right) panel. The blue dashed lines stand for the $J/\psi\pi$–$D^*\bar{D}$ coupled-channel-analysis results, and the red solid lines show the energy levels obtained when the inelastic $J/\psi\pi$–$D^*\bar{D}$ transition is neglected ($C = 0$). This latter case corresponds to consider a single, elastic channel ($D^*\bar{D}$). The error bands account for the uncertainties on the energy levels inherited from the errors in the parameters of Ref. [35], quoted in Table I (statistical and systematical errors are added in quadrature for the calculations).

The green dashed (dotted-dashed) lines stand for the non-interacting $D^*\bar{D}$ ($J/\psi\pi$) energy levels. In Fig. 2, the same results are shown but for the case $\Lambda_2 = 0.5$ GeV. The qualitative $L$ behavior of both Figs. 1 and 2 is similar, so we discuss first Fig. 1 and, later on, the specific differences between them will be outlined.

For both resonant and virtual scenarios, there is always an energy level very close to a free energy of the $J/\psi\pi$ state, $E_{J/\psi\pi}^{(1)}$, which reveals that the interaction driven by this meson pair is weak. Furthermore, the energy levels for the coupled-channel $T$-matrix basically follow those obtained within the elastic $D^*\bar{D}$ approximation, except in the neighborhood of the $J/\psi\pi$ free energies. This also corroborates that the role of the $J/\psi\pi$ is not essential.

Let us pay attention to the levels placed in the vicinity of the $D^*\bar{D}$ threshold. For simplicity, we first look at the single elastic channel case. There appears always a state just below threshold, as it should occur since we are putting an attractive interaction in a finite box. As the size of the box increases, and since there is no bound state in the infinite volume limit (physical case), this level approaches to threshold. When the $J/\psi\pi$ channel is switched on, the $L$–behaviour of this level will be modified, specially when it is close to a discrete $J/\psi\pi$ free energy. Note that the slopes of the $J/\psi\pi$ free levels, in the range of energies considered here, are larger (in absolute value) than those of the $D^*\bar{D}$ ones, because the threshold of the $J/\psi\pi$ channel is far from the region studied.

From the above discussion, one realizes that the next coupled channel energy level, located between the two $D^*\bar{D}$ free ones ($E_{D^*\bar{D}}^{(1)}$ and $E_{D^*\bar{D}}^{(2)}$), could be more convenient to extract details of the $Z_c(3900)^*$ dynamics. Indeed, in the resonance scenario, this second energy level is very shifted downwards with respect to $E_{D^*\bar{D}}^{(1)}$ since it is attracted towards the $Z_c$ resonance energy. In this context, it should be noted that the presence of $Z_c(3900)^*$ does not induce the appearance of an additional energy level, but a sizeable shift of the energy levels with respect to the non-interacting ones. Therefore, even if no extra energy level appears, it would not be possible to completely discard the existence of a physical state (resonance). The energy shift, however, can be quite large and, only in this sense, one might speak of the appearance of an additional energy level. The correction of the second energy level in the virtual state scenario is much less pronounced. We should note here that the elastic phase shift computed with the $T$-matrix in Ref. [35] does not follow the pattern of a standard Breit-Wigner distribution associated to a narrow resonance. Indeed, the phase shift does not change quickly from 0 to $\pi$ in the vicinity of the $Z_c(3900)$ mass, and actually it does not even reach $\pi/2$. This is mostly due to a sizeable background in the amplitude.

We now compare the cases $\Lambda_2 = 1$ GeV (Fig. 1) and $\Lambda_2 = 0.5$ GeV (Fig. 2). For $\Lambda_2 = 0.5$ GeV, the relevant (second) energy level is more shifted with respect to $E_{D^*\bar{D}}^{(1)}$ in the resonance scenario (Fig. 2, left) than in the virtual scenario (Fig. 2, right). This is the same behaviour already discussed for $\Lambda_2 = 1$ GeV. However, the shift for the resonance scenario is smaller in the $\Lambda_2 = 0.5$ GeV case (Fig. 2, left) than in the $\Lambda_2 = 1$ GeV one (Fig. 1, left). This is due to the fact that the $Z_c(3900)^*$ is closer to the threshold and the coupling to $D^*\bar{D}$ is smaller for the $\Lambda_2 = 0.5$ GeV case. Another important difference between the $\Lambda_2 = 1$ GeV and $\Lambda_2 = 0.5$ GeV results is that the error band of the relevant energy level is smaller when the lighter cutoff is used. This is due to the different relative errors in both cases, and the fact that for $\Lambda_2 = 0.5$ GeV, the relevant level is closer to the $E_{D^*\bar{D}}^{(1)}$ free energy than in the $\Lambda_2 = 1$ GeV case.

After having explored the volume dependence of the energy levels predicted with our $T$-matrix and scrutinized its physical meaning, we can now compare our results with those reported in Ref. [48]. The energy levels in the latter work are obtained from a single volume simulation, $L = 1.98 \pm 0.02$ fm, and

---

1 For physical pions ($m_\pi \sim 140$ MeV), the $Z_c$ resonance mass, ignoring errors, is $3894$ MeV ($3886$ MeV) for $\Lambda_2 = 1$ GeV ($0.5$ GeV), as seen from Table I. For $m_\pi = 266$ MeV as used in Ref. [48], and taking into account the shift in Eq. (18), one might estimate that mass to be around $3912$ MeV ($3902$ MeV).

2 This is also discussed in more detail in Ref. [53].

3 For $m_\pi = 266$ MeV as used in Ref. [48], and taking into account the shift in Eq. (18), one might estimate that mass to be around $3912$ MeV ($3902$ MeV).
are shown in Fig. 3 with black squares. In the figure, we also show the results obtained in this work for $L = 2$ fm, for both the resonance (filled circles) and virtual state (empty circles) scenarios for the $Z_c(3900)$. Besides, the energy levels calculated with $\Lambda_2 = 1$ GeV and $\Lambda_2 = 0.5$ GeV are represented in blue and green, respectively. We provide two different error bars for our results, considering only the uncertainties of the parameters entering in the $T$-matrix (Table I), or additionally taking into account the errors of the lattice parameters (Table II). We clearly see three distinct regions, the lowest energies are very close to the $D\bar{D}$ threshold ($E_{D\bar{D}}^{(0)}$) and to the first $J/\psi\pi$ free energy level ($E_{J/\psi\pi}^{(1)}$). These free energies are shown in Fig. 3 with red solid horizontal lines. As expected, the two lowest lattice levels agree well with our results for both cutoffs and the two $Z_c(3900)$ state interpretations examined in this work. The higher energy levels are the relevant ones, and, as already mentioned, our results are significantly shifted to lower energies with respect to $E_{D\bar{D}}^{(1)}$ for the resonant scenario, while this shift is much smaller for the virtual state one. In general, the lattice results are in very good agreement with the virtual state scenario level for both $\Lambda_2 = 0.5$ GeV and $\Lambda_2 = 1$ GeV cases, whereas in the resonance scenario the agreement is also very good for $\Lambda_2 = 0.5$ GeV, and it is not so good for $\Lambda_2 = 1$ GeV. However, in the latter case, we find $E_{th} = 4000_{-24}^{+26}$ MeV, while the lattice energy is $E_{lat} = 4070 \pm 30$ MeV [48], and hence this non-compatibility is small, the difference being $E_{lat} - E_{th} = 70 \pm 40$ MeV. The comparison of our results with those of Ref. [48] support the conclusions given in the latter work: from the energy levels found in that QCD simulation one cannot deduce the existence of a resonance (a truly physical state, instead of a virtual scenario for $\Lambda_2 = 1$ GeV). But also from this comparison, putting this conclusion in the other way around, one cannot discard its existence either.

Finally, as can be seen in Fig. 3, a comparison of the relevant energy level obtained in the resonance scenario for $\Lambda_2 = 0.5$ GeV (green filled circle) with that obtained in the virtual scenario for $\Lambda_2 = 1$ GeV (blue empty circle) shows that, within theoretical uncertainties (the smallest error bars), both cases are indistinguishable. This fact can already be seen by comparing the left panel of Fig. 2 and the right panel of Fig. 1 around $L \approx 2$ fm. These energy levels are shown together in Fig. 4. It can be seen that, although these two scenarios cannot be distinguished at $L \approx 2$ fm (the volume used
With the aim of shedding light into the nature of the $Z_c(3900)$ state, we have implemented the $J/\psi\pi$, $D^*\bar{D}$ coupled channel $T$-matrix of Ref. [35] in a finite volume, and we have compared our predictions with the results obtained in the LQCD simulation of Ref. [48]. The model of Ref. [35] provides a similar good description of the experimental information concerning the $Z_c(3900)$ structure in two different scenarios. In the first one, the $Z_c(3900)$ structure is due to a resonance originating from the $D^*\bar{D}$ interaction, while in the second one it is produced by the existence of a virtual state. We have studied the dependence of the energy levels on the size of the finite box for both scenarios. For the volume used in Ref. [48], our results compare well with the energy levels obtained in the LQCD simulation of Ref. [48]. However, the agreement is similar in both scenarios (resonant and virtual) and hence it is not possible to privilege one over the other. Therefore and in order to clarify the nature of the $Z_c(3900)$ state, we suggest performing further LQCD simulations at different volumes to study the volume dependence of the energy levels.

**IV. SUMMARY**

in Ref. [48]), they lead to appreciably different energies already at $L \approx 2.5$ fm. This means that one cannot elucidate the nature of this intriguing $Z_c(3900)$ state with LQCD simulations performed in a single volume. Rather, it would be useful to perform simulations at different values of the box size, to properly study the volume dependence of the energy levels. Of course, as discussed in Ref. [48], this would bring in a technical problem—the appearance of more $J/\psi\pi$ free energy levels in the energy region of interest, as can be seen in

---

**FIG. 3.** Comparison of the energy levels of Ref. [48], shown with black squares, with our results for $L \approx 2$ fm. Full (empty) circles stand for the energy levels obtained in the resonance (virtual state) scenario for the $Z_c(3900)$ state. On the other hand, the energy levels for the $\Lambda_2 \simeq 1$ GeV (0.5 GeV) case are shown by blue (green) circles. The energy levels calculated in this work are displayed with two types of error bars: the smaller ones have been obtained considering only the errors of the parameters entering in the $T$-matrix (Table I), whereas the larger ones additionally take into account the errors of the lattice parameters (Table II).

**FIG. 4.** Comparison of the relevant energy level for the $\Lambda_2 = 1$ GeV virtual state (solid purple lines) and the $\Lambda_2 = 0.5$ GeV resonance scenarios (dashed blue lines) around $L \approx 2$ fm. The green dashed and dashed-dotted lines represent $E_{D^*\bar{D}}^{(1)}$ and $E_{J/\psi\pi}^{(2)}$ non-interacting energies, respectively.
ACKNOWLEDGMENTS

We would like to thank S. Prelovsek for reading the manuscript and for useful discussions. M. A. acknowledges financial support from the “Juan de la Cierva” program (27-13-463B-731) from the Spanish MINECO.
