COMPLEX TOPOLOGICAL SOLITON WITH REAL ENERGY IN
PARTICLE PHYSICS

ABSTRACT. We summarise the procedure used to find the classical masses of Higgs particle, massive
gauge boson and t’Hooft-Polyakov monopole in non-Hermitian gauge field theory. Their physical
regions are explored, and the mechanism of the real value of the monopole solution is analysed in
different physical regions.

KEYWORDS: t’Hooft-Polyakov monopole, quantum field theory, non-Hermitian quantum field theory.

1. INTRODUCTION

Quantum field theory is a key tool to analyse particle
physics. The most modern physical description of
the fundamental particle interaction is described by
the model called the Standard Model. However, the
model possesses several problems such as incompatibil-
ity with the general relativity, hierarchy problem, etc.
Therefore, it is an active area to extend the standard
model.

Recently a growing number of research papers
started exploring the non-Hermitian extension of the
Standard Model. We have contributed to
this development by analysing the Goldstone theo-
rem. The Higgs mechanism and t’Hooft-
Polyakov monopoles. The classical masses of
Higgs particles, massive gauge boson and monopoles
were analysed. However, a detailed analysis of their
intersecting physical regions and the mechanism of the
real value of the energy of monopole was not explored.
The main aim of this contribution is to fill this gap.

There are two separate mechanisms that guarantee
the real value of the particle masses in question. First,
the masses of Higgs particles are given by a non-
Hermitian mass matrix \( M \). Assume that the matrix
possess anti-linear symmetry, which we refer to as
\( PT \) symmetry, that satisfies \( [PT, M] = 0 \), \( Mv = \lambda v \), \( PTv = e^{i\theta}v \), where \( \{v, \lambda\} \) are eigenvectors and
eigenvalues of the mass matrix. From this, it is trivial
to show that the eigenvalues are real

\[
PTMv = \lambda PTv = \lambda PTMv = \lambda PTMv = \lambda e^{i\theta}v,
\]

It was shown in [8] that this \( PT \) symmetry is related to the \( CPT \) symmetry of the field-theoretic
action.

On the other hand, the classical energy of the soli-
ton solution is found by inserting the solution into the
Hamiltonian \( E = H[\phi] = \int d^3xH(\phi) \). Therefore, the techniques from \( PT \) symmetric quantum mechanics
shown above can not be applied.

We will show below that the energy of the soliton
solutions are real when the three conditions stated
below holds. Therefore they are sufficient condi-
tions to guarantee the real value of particles in the model.
However, we do not claim that these are necessary
conditions.

Let \( \{\phi_1, \phi_2\} \) be a set of distinct (or identi-
cal) solutions to the equations of motion \( \delta L/\delta\phi \rightarrow
\partial_\mu(\delta L/\partial\partial_\mu\phi) = 0 \), where \( L(\phi) \) is the field-theoretic
Lagrangian density. The classical energies of the soli-
tion are given by inserting the solution into the
Hamiltonian, \( E_i = H[\phi_i] = \int d^3xH(\phi_i) \), for \( i \in \{1, 2\} \).
The classical mass of the solution \( \phi_1 \) and \( \phi_2 \) are real if there exist some anti-linear symmetry \( CPT \) (note
that is it not the standard \( CPT \) symmetry in quantum
field theory) such that three conditions are satisfied:

1. \( CPT : H[\phi(x)] \rightarrow \chi(PT\phi(x)) = \chi[\phi(-x)] \).
2. \( CPT : \chi(1) \rightarrow \phi_2(-x) \).
3. \( H[\phi_1] = H[\phi_2] \).

If two solutions are identical \( \phi_1 = \phi_2 \), then the above
condition reduces to the reality condition of the soli-
ton solution already derived in [15]. Using the above three
conditions, the real value of the classical mass can
easily be shown by the following argument

\[
\int d^3xH[\chi(PT\phi(x))] \quad \Rightarrow \quad \int d^3xH[\chi(-x)] = M_1^2,
\]

\[
\Rightarrow \quad M_1^2 = M_2^2 \quad \Rightarrow \quad M_1^2 = M_1,
\]

where numbers above the equal signs indicate the
condition number.

The above analysis can be performed directly on
the complex model. However, the non-Hermitian
theory is only well-defined once the inner-product
is identified. The modern way of the well-defined
non-Hermitian quantum mechanics was first realised
by Frederik Scholtz, Hendrik Geyer, and Fritz Hahne
in 1992 [10]. The authors used the mathematical
condition on the operator called the quasi-Hermiticity
(the term was first coined in [17], but the metric was...
not given) to define the positive definite inner product. The quasi-Hermiticity is defined as a condition on the bounded linear operator of the Hilbert space \( A : \mathcal{H} \to \mathcal{H} \), which satisfies

(i) \( \langle v | \rho w \rangle > 0 \) for all \( |v \rangle \in \mathcal{H} \) and \( |v \rangle \neq 0 \).

(ii) \( \rho A = A^\dagger \rho \).

Where the bounded Hermitian linear operator \( \rho : \mathcal{H} \to \mathcal{H} \) is often called the metric operator because the inner product is defined by the operator \( \langle | \rho \rangle := \langle | \rho | \rangle \) restores the Hermiticity of the operator. This result can be shown by using the condition (ii)

\[
\langle v | A^\dagger \rho w \rangle = \langle v | A^\dagger \rho w \rangle = \langle A v | \rho w \rangle = \langle A v | \rho w \rangle,
\]

for all \( |v \rangle, |w \rangle \in \mathcal{H} \). Note that the quasi-Hermiticity alone does not guarantee the real energy spectrum of the Hamiltonian. In fact, one requires two extra conditions.

(iii) The metric operator is invertible.

(iv) \( \rho = \eta^\dagger \eta \).

The operator which satisfies only conditions (ii) and (iv) is referred to as the pseudo-Hermitian operator, which was first introduced in [13]. These extra conditions were considered in [10] to prove that, given a set of pseudo-Hermitian operators \( A = \{ A_I \} \), the metric operator \( \rho_A \) which satisfies conditions (i), (ii), (iii) and (iv) for all operators of set \( A \) is uniquely determined if and only if all operators of the set \( A \) are irreducible on the Hilbert space \( \mathcal{H} \). This procedure is analogous to the Dyson mapping first introduced by Freeman Dyson [13] used in the study of nuclear reaction [20][22], which maps the non-Hermitian operator \( A \) to Hermitian operator \( \eta^{-1} A \eta \) via Dyson map \( \eta \). The relation between the metric operator and the Dyson map is found by utilising the Hermiticity of the expression \( \eta^{-1} A \eta \) in the following way

\[
\eta^{-1} A \eta = (\eta^{-1} A \eta)^\dagger \implies A \eta = \eta \eta^\dagger A \implies \eta \eta = \rho.
\]

We will utilise this mapping to transform the non-Hermitian field-theoretic Hamiltonian to a Hermitian Hamiltonian. This procedure will resolve the issue of complex vacuum solution and Derrick's scaling argument, as we will see below. However, we note that the Dyson map used here introduces a negative kinetic sign in the kinetic term of one of the fields, indicating the ghost field problem. This issue is removed if one further diagonalise the Hamiltonian. Such diagonalisation can be realised via field-redefinition or via another Dyson map. A more detailed discussion of this is found in [23], and a Dyson map which diagonalise the free part of the non-Hermitian Hamiltonian is found in [12].

2. Methods

In this section, we will summarise the method used in [8][11] to find the masses of the Higgs particles, massive gauge particles and 't Hooft-Polyakov monopoles in non-Hermitian gauge field theory. We note that the explicit forms of the similarity transformation will not be discussed in this paper as non-Hermitian and Hermitian theories are isospectral as long as the CPT symmetry is preserved for Hamiltonian, Higgs particles and monopole solution.

We begin with the non-Hermitian local SU(2) gauge theory with matter fields in the adjoint representation

\[
L_2^{\text{ad}} = \frac{1}{4} \text{Tr} (D_\mu \phi_1)^2 + \frac{m_1^2}{4} \text{Tr} (\phi_1^2) + \frac{\mu_2^2}{2} \text{Tr} (\phi_1 \phi_2) - \frac{g}{64} \left[ \text{Tr} (\phi_1^2) \right]^2 + \frac{1}{4} \text{Tr} (D_\mu \phi_2)^2 + \frac{m_2^2}{4} \text{Tr} (\phi_2^2) - \frac{1}{8} \text{Tr} (F^2).
\]

Here we take \( g, \mu \in \mathbb{R}, m_1 \in \mathbb{R} \) and discrete values \( c_i \in \{-1, 1\} \). The two fields \( \{ \phi \}_{i=1,2} \) are Hermitian matrices \( \phi_i (t, \vec{x}) \equiv \phi_i(t, \vec{x}) T^a \), where \( \phi_i(t, \vec{x}) \) is a real valued field. The three generators \( T^a \) of SU(2) in the adjoint representation are defined by three Hermitian matrices of the form \( T^a_{abc} = -i \epsilon_{abc} \), satisfying the commutation relation \( [T^a, T^b] = i \epsilon_{abc} T^c \). One can check that \( T^a T^b T^c = 2 \delta_{ab} \). The field strength tensor is defined as \( F_{\mu\nu} = \partial_\mu \phi_2 - \partial_\nu \phi_1 - i [\phi_1, \phi_2] \), where the gauge fields are \( \phi_i = A_\mu^i T^a \). The partial derivative is replaced with the covariant derivative \( (D_\mu \phi_i)^a := \partial_\mu \phi_i^a + i e_{abc} A_\mu^b \phi_c^a \) to compensate for the local symmetry group SU(2).

This action is invariant under the local SU(2) transformation of the matter fields \( \phi_i \rightarrow e^{i \sigma^a (x) T^a} \phi_i e^{-i \sigma^a (x) T^a} \) and gauge fields \( A_\mu \rightarrow e^{i \sigma^a (x) T^a} A_\mu e^{-i \sigma^a (x) T^a} + i \delta_{\mu \nu} \alpha^a (x) T^a \). It is also symmetric under modified CPT symmetry, which transforms two fields, \( \phi_1 \) and \( \phi_2 \) as

\[
\text{CPT} : \phi_1 (t, \vec{x}) \rightarrow \phi_1 (-t, -\vec{x}) \quad \phi_2 (t, \vec{x}) \rightarrow -\phi_2 (-t, -\vec{x}) \quad i \rightarrow -i.
\]

The equations of motion for the fields \( \phi_i \) and \( A_\mu \) of the Lagrangian (2) are

\[
(D_\mu D^\mu \phi_i)^a + \frac{\delta V}{\delta \phi_i^a} = 0,
\]

\[
D_\mu F^\mu\nu - c e_{abc} \partial_\mu \phi^b_c (D^\nu \phi)^c + c e_{abc} \partial_\mu \phi^b_c (D^\nu \phi)^c = 0,
\]

where repeated indices are summed over. We perform the similarity transformation of the complex Lagrangian (2) by momentary resorting to a quantum theory where we assume an equal time commutation relation between the fields \( \phi_i \) and their canonical momenta \( \Pi^i = \partial_\mu \phi_i^a \), satisfying the commutation relation \( [\phi^a_i (t, \vec{x}), \Pi^i_j (t, \vec{y})] = \delta (\vec{x} - \vec{y}) \delta_{ij} \delta_{ab} \). Using this relation, we can transform the corresponding complex Hamiltonian of the Lagrangian (2) by

\[
H \rightarrow e^{\eta H} H e^{-\eta H},
\]

\[
\eta_{\pm} = \prod_{i=1}^3 \exp \left( \pm \frac{i}{2} \int d^4 x \Pi^i_2 \phi^a_i \right),
\]

where \( H \) is the field-theoretic Hamiltonian of our model (2), obtained via Legendre transformation. This non-uniqueness of the metric is analogous to
the non-uniqueness of the metric and its connection to the observables in the quantum mechanical setting discussed in [16, 24]. The adjoint action of \( \eta_{\pm} \) maps the complex action in the equation (2) into the following real action

\[
\mathcal{L}_{\pm} = \frac{1}{2} \left( -\mathcal{L} + \mathcal{L} \right)
\]

The parameter \( c_3 \) indicates the different similarity transformations by taking the values \( \pm 1 \) for \( \eta_{\pm} \), respectively.

For convenience, let us rewrite the above real action in terms of each component of the fields \( \phi_i^a \) as

\[
\mathcal{L}_{\pm}^a = \frac{1}{2} \left( D_{\mu} \phi_i^a \right) \left( D_{\mu} \phi_i^a \right)^a + \frac{1}{4} \left( D_{\mu} \phi_i^a \right) \left( D_{\mu} \phi_i^a \right)^a
\]

where the matrices \( H, \mathcal{I} \) and \( E \) are defined as

\[
H := \begin{pmatrix} m_1^2 & -\mu^2 \\ -\mu^2 & m_2^2 \end{pmatrix}, \quad \mathcal{I} := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad E := \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}
\]

2.1. Higgs and Gauge Masses

Next, we define the trivial solution of the equations of motion by solving \( SN = 0 \) and \( D_{\mu} \phi_i = 0 \). Such vacuum is often referred to as Higgs vacuum. The first equation can be simplified by choosing an Ansatz \( \phi_i^a(t, \vec{x}) = \hat{h}_i^a \hat{r}^a \hat{r} \) where \( \hat{r} = (x, y, z) / \sqrt{x^2 + y^2 + z^2} \) and \( \hat{r}^a \) are some constants to be determined. Note that the vacuum solution has a rotational symmetry \( SO(3) \) since \( \hat{r}^a \hat{r} = 1 \). Inserting this Ansatz into the equation (7), we find

\[
V = -\frac{1}{2} h_{ij} h_{ij} + \frac{g}{16} h_{ij} h_{ij}
\]

Then the vacuum equation \( 5V = 0 \) is reduced to simple coupled third order algebraic equations

\[
\begin{align*}
\frac{g}{4} (h_0^0)^2 - c_1 m_1^2 h_0^0 + c_3 \mu^2 h_0^0 &= 0, \\
c_2 m_2^2 h_0^0 + c_3 \mu^2 h_0^0 &= 0, \\
D_{\mu} \phi_i &= 0.
\end{align*}
\]

The resulting vacuum solutions are

\[
\begin{align*}
h_0^0 &= -\frac{c_2 m_2^2}{m_1^2} h_0^0, \\
(h_0^0)^2 &= 4 \frac{c_2 m_2^2 m_1^2}{m_2^2} := R^2, \\
(A_0^0)^a &= -\frac{1}{3r} e^{i\alpha r^2} + \hat{r}^a A_i, \quad (A_0^0)^a = 0.
\end{align*}
\]

The \( A_i \) are arbitrary functions of space-time. The Higgs particle can be identified with the fundamental fields of the theory after spontaneous symmetry breaking of the continuous symmetry \( SU(2) \) by Taylor expanding around the vacuum solution. Performing a Taylor expansion around the Higgs vacuum and keeping a focus on the second-order terms with only matter fields \( \phi_i^a \), the real Lagrangian \( \mathcal{L} \) contains the following term

\[
\mathcal{L} = \int d^4x \frac{1}{2} \phi_i^a (-\partial_{\mu} \phi_i^a I_{ij} \delta_{ab} - \hat{H}_{ij}^a) \phi_j^b + \ldots,
\]

where \( \hat{H} \) is a 6 × 6 diagonal Hermitian matrix. After diagonalising the above term by redefining the fields with the eigenvectors of the non-Hermitian mass matrix \( M_{ab} := I_{ab} \delta_{ij} \hat{H}_{ij}^a \), we find that the masses of the fundamental fields after the symmetry breaking to be equal to the eigenvalues of \( M_{ab} \) given as

\[
m_0^2 = c_2 \mu^2 - m_2^2 m_1^2, \quad m_\pm = K \pm \sqrt{K^2 + 2L},
\]

where \( K = c_1 m_1^2 - 2 c_2 m_2^2 + \frac{2 a_4}{a_2 m_2^2} \) and \( L = \mu^4 + c_1 c_2 m_1^2 m_2^2 \). Notice that only find three non-zero eigenvalues.

2.2. t'Hooft-Polyakov Monopole

To find the monopole solutions, let us consider the following Ansatz

\[
(\phi_i^{cl})^a(\vec{x}) = h_i(r)^a, \quad (A_i^{cl})^a = e^{i\alpha r^\mu} A_i^\mu(\vec{x}),
\]

where the subscript \( cl \) denotes the classical solutions to the equations of motion (14). The difference between this Ansatz (14) and the Higgs vacuum (11)}
is that the quantity $h_1$ now depends on the spatial radius $h_1 = h_1(r)$. Here we are only considering the static Ansatz to simplify our calculation, but one may, of course, also consider the time-dependent solution by utilising the Lorentz symmetry of the model and performing a Lorentz boost. According to Derrick’s scaling argument [25], for the monopole solution to have finite energy, we require the two matter fields of the equation (14) to approach the vacuum solutions in the equation (11) at spatial infinity

$$\lim_{r \to \infty} h_1(r) = h_{1}^{0} = \pm R, \quad \lim_{r \to \infty} h_2(r) = h_{2}^{0} = \mp \frac{c_2 c_3 \mu^2}{m^2} R. \quad (15)$$

Also, notice that at some fixed value of the radius $r$, the vacuum solutions $\phi_0^i$ and monopole solutions $\phi_3^i$ both belong to the 2-sphere in the field configuration space. For example, $\phi_3^i$ belongs to the 2-sphere with radius $R$ because $(\phi_3^i)^2 = R^2$. Therefore, solutions $\phi_3^i$ can be seen as a mapping between 2-sphere in space-time (where the radius is given by the profile function $h_2$) to 2-sphere in field configuration space. Such mapping has a topological number called the winding number $n \in \mathbb{Z}$, which can be explicitly realised by redefining the unit vector $\hat{r}_n$ as

$$\hat{r}_n = \left( \frac{\sin(\theta) \cos(n \varphi)}{\cos(\theta)}, \frac{\sin(\theta) \sin(n \varphi)}{\cos(\theta)} \right). \quad (16)$$

Therefore different $n$ represent topologically inequivalent solutions.

Since we require the monopole and vacuum solutions to smoothly deformed into each other at spacial infinity, both solutions need to share the same winding number. It is important to note that winding numbers of $\phi_1$ and $\phi_2$ need to be equal to satisfy $D\phi_1 = D\phi_2 = 0$, and therefore we will denote the winding numbers of $\phi_1$ and $\phi_2$ as $n_1$ and $n_2$ respectively. If they are not equal, we would have $D\phi_1 = 0$ but $D\phi_2 \neq 0$. Next, let us insert our Ansatz equation (14) into the equations of motion equation (4). We will also redefine the gauge for the gauge fields to be $A^a_0 = e^{i a \beta} \rho_b \left( \frac{1 - u(r)}{r^2} \right)$, $A^0_3 = 0$, which are more in line with the original Ansatz given in [26, 27], compared to equation (14). Inserting these expressions into the equations of motion equation (4), we find

$$u''(r) + \frac{u(r)}{r} \left[ 1 - u^2(r) \right] \quad (17)$$

$$+ \frac{c_2 u(r)}{2} \left\{ h_2''(r) - h_1''(r) \right\} = 0,$$

$$h_2''(r) + \frac{2h_1'(r)}{r} - \frac{2h_1(r)u^2(r)}{r^2} \quad (18)$$

$$+ g \left\{ -c_1 \frac{m^2}{g} h_1(r) + c_3 \frac{\mu^2}{g} h_2(r) + \frac{1}{2} h_3''(r) \right\} = 0,$$

$$h_2''(r) + \frac{2h_1'(r)}{r} - \frac{2h_1(r)u^2(r)}{r^2} \quad (19)$$

$$+ c_2 m^2 \left\{ h_2(r) + c_3 \frac{\mu^2}{m^2} h_1(r) \right\} = 0.$$

Notice that these differential equations are similar to the ones discussed in [26, 27], but with the extra field $h_2$ and extra differential equation (19). In the Hermitian model, the exact solutions to the differential equations were found by taking the parameter limit called the BPS limit [26, 27], where parameters in the Hermitian model are taken to zero while keeping the vacuum solution finite. Here we will follow the same procedure and take the parameter limit where quantities in the curly brackets of equations (18) and (19) vanish but keep the vacuum solutions equation (11) finite. We will see in section 2.4 that we also find the approximate solutions in this limit.

### 2.3. The Energy Bound

Surprisingly, by utilising Derrick’s scaling argument, one can find the lower bound of the monopole energy without the explicit form of the solution.

The energy of the monopole can be found by inserting the monopole solution into the corresponding Hamiltonian of equation (6).

$$h = \int d^3x \; Tr \left[ E^2 \right] + \frac{1}{2} \int d^3x \; Tr \left[ B^2 \right] + \frac{1}{2} \int d^3x \; Tr \left[ (D_i \phi_3)^2 \right] - \frac{1}{2} \int d^3x \; Tr \left[ (D_i \phi_1)^2 \right] + \frac{1}{2} \int d^3x \; Tr \left[ (D_i \phi_2)^2 \right] + V, \quad (20)$$

where $E, B$ are $E^a_i = F^a_{ik} \rho^k$, $B^a_i = -\frac{1}{2} \epsilon^{ijk} F^a_{jk}$, $i, j, k \in \{1, 2, 3\}$. The gauge is fixed to be the radiation gauge (i.e $A^0_a = 0, \partial_t A^a_i = 0$). Notice that our monopole Ansatz equation (10) is static with no electric charge $E^a_0 = 0$ and therefore, the above Hamiltonian reduces to

$$E = \int d^3x \; Tr \left[ B^2 \right] + \frac{1}{2} \int d^3x \; Tr \left[ (D_i \phi_3)^2 \right] \quad (21)$$

$$- \frac{1}{2} \int d^3x \; Tr \left[ (D_i \phi_1)^2 \right] + \frac{1}{2} \int d^3x \; Tr \left[ (D_i \phi_2)^2 \right] + V,$$

$$= \frac{1}{2} \int d^3x \; B_i^a B_i^a + \frac{1}{2} \int d^3x \; (D_i \phi_3)^a (D_i \phi_1)^a + \frac{1}{2} \int d^3x \; (D_i \phi_2)^a (D_i \phi_2)^a + \frac{1}{2} \int d^3x \; V.$$

Here, we simplified our expression by dropping the superscripts $A^a_i \rightarrow A_i$, $\phi^a_i \rightarrow \phi_i$. We also keep in mind that these fields depend on the winding numbers $n \in \mathbb{Z}$. In the Hermitian model (i.e. when $\phi_3 = 0$), one can rewrite the kinetic term as $B^2 + D \phi^2 = (B - D \phi)^2 + 2BD\phi$ and find the lower bound to be $\int 2BD\phi$. Here we will follow a similar procedure but introduce some arbitrary constant $\alpha, \beta \in \mathbb{R}$ such that $B^2 = \alpha^2 B - \beta^2 B$ where $\alpha^2 = \beta^2 = 1$. This will allow
us to rewrite the above energy as
\[
E = 2 \int d^3x \, \alpha^2 \left\{ B_i^a + \frac{1}{\alpha} (D_i \phi_1)^a \right\}^2 \quad (22)
\]
\[-\beta^2 \left\{ B_i^a + \frac{1}{\beta} (D_i \phi_2)^a \right\}^2 + 2 \left\{ -\alpha B_i^a (D_i \phi_1)^a + \beta B_i^a (D_i \phi_2)^a \right\} + \frac{1}{V}. \]

To proceed from here, we need to assume extra constraints on \( \alpha \) and \( \beta \) such that the following inequalities are true
\[
\int d^3x \, \alpha^2 \left\{ B_i^a + \frac{1}{\alpha} (D_i \phi_1)^a \right\}^2 = 0,
\]
\[-\beta^2 \left\{ B_i^a + \frac{1}{\beta} (D_i \phi_2)^a \right\}^2 \geq 0, \quad \int d^3x V \geq 0.
\]  
With these constraints we can now write down the lower bound of the monopole as
\[
E \geq 2 \int d^3x \left\{ -\alpha B_i^a (D_i \phi_1)^a + \beta B_i^a (D_i \phi_2)^a \right\} \quad (24)
\]
\[= 2 \int d^3x \left\{ -\alpha \left\{ B_i^a \partial_\alpha \phi_1^a + e B_i^a e^{abc} A^b \phi_1^c \right\} + \beta \left\{ B_i^a \partial_\alpha \phi_2^a + e B_i^a e^{abc} A^b \phi_2^c \right\} \right\} \]
\[= 2 \int d^3x \left\{ -\alpha \left\{ B_i^a \partial_\alpha \phi_1^a + (-e^{abc} A^b \phi_1^c) \phi_1^a - \beta \left\{ B_i^a \partial_\alpha \phi_2^a + (-e^{abc} A^b \phi_2^c) \phi_2^a \right\} \right\} \right\} \]
\[= 2 \int d^3x \left\{ -\alpha \partial_\alpha (B_i^a \phi_1^a) + \beta \partial_\alpha (B_i^a \phi_2^a) \right\} \]
\[= \lim_{r \to \infty} \left( -2\alpha \int_{S_r} ds_i B_i^a \phi_1^a + 2\beta \int_{S_r} ds_i B_i^a \phi_2^a \right), \]
where in the fourth line, we used \( D_i B_i^a = 0 \), which can be shown from the Bianchi identity \( \partial_i \varepsilon_\mu \varepsilon_\nu \varepsilon_\rho F_{\mu \nu \rho} = 0 \). The last line is obtained by using the Gauss theorem at some fixed value of the radius \( r \). Since the \( \phi_i^a \) in the integrand is only defined over the 2-sphere with a large radius, we can use the asymptotic conditions \(^{[15]} \) and replace the monopole solutions \( \{ \phi_i^a, B_i^a \} \) with the Higgs vacuum \( \{ (\phi_0^a)^2, (B_0^a)^2 \} \)
\[
E \geq \left( -2\alpha (\phi_0^a)^2 + 2\beta (\phi_0^a)^2 \right) \lim_{r \to \infty} \int_{S_r} ds_i (B_i^0)^a \quad (25)
\]
\[= \left( \pm 2\pi m_n a \right) \frac{e^{2 \epsilon \alpha \mu}}{m_2} \frac{m_n a}{m_2} \lim_{r \to \infty} \int_{S_r} ds_i (B_i^0)^a, \]
where the upper and lower signs of the above energy correspond to the upper and lower signs of the vacuum solutions in equation \(^{[11]} \). The explicit value of \( B_i^a \) can be obtained by inserting the Higgs vacuum \(^{[11]} \) into the definition of the magnetic field
\[
B_i^a = -\frac{1}{2} \epsilon^{ijk} (\partial_j A_k - \partial_k A_j + e A_j \times A_k)^a. \quad (26)
\]
After a lengthy calculation, this expression can be simplified to \( B_i^a = \hat{\phi}^a, b_i = \hat{\phi}^a \), where \( \hat{\phi}^a \) is a normalised solution \( \sum_a \phi_i^a \hat{\phi}^a = 1 \). The \( b_i \) is defined as
\[
b_i \equiv -\frac{1}{2} \epsilon_{ijk} \left\{ \partial^j A^k - \hat{\phi}^k A^i + \frac{1}{e} r_n \cdot \left( \partial^j r_n \times \hat{\phi}^k \right) \right\}. \quad (27)
\]
When \( A \) was defined in equation \(^{[11]} \). Notice that integrating the first term over the 2-sphere gives zero by Stoke’s theorem \( \int _{S_2} \partial \times A = \int _{S_2} A = 0 \), where one can show that Stoke’s theorem on the closed surface gives zero by dividing the sphere into two open surfaces. The second term is a topological term which can be evaluated as
\[
\int ds_i B_i = -\frac{4\pi m_n}{e}. \quad (28)
\]

The explicit calculation is in \(^{[28]} \). This is the magnetic charge of the monopole solutions. Therefore integer \( n \), which corresponds to the winding number of the solution, comes from the Ansatz \( B_n^a = \hat{\phi}^a \). In our case, there is an ambiguity of whether to choose \( B_n^a = \hat{\phi}^a \) or \( B_n^a = \hat{\phi}^a \). Now we see explicitly the reason why we choose to keep the same integer values for solutions \( \hat{\phi}^1 \) and \( \hat{\phi}^2 \). If the integer values of \( r_n \) in solutions \( \hat{\phi}^1 \), \( \hat{\phi}^2 \) are different, then the integration \( \int _{S_2} B_n^a (B_n^a)^a \) will be different, leading to inconsistent energy.

Finally, we find our lower bound of the monopole energy
\[
E \geq \mp 2R \left( \alpha + \beta \frac{e^{2 \epsilon \alpha \mu}}{m_2} \frac{m_n a}{m_2} \right) \frac{4\pi m_n}{e}. \quad (29)
\]
Notice that we have some freedom to choose \( \alpha, \beta \in \mathbb{R} \) as long as our initial assumptions \(^{[23]} \) are satisfied. We will see in the next section that we can take a parameter limit of our model, which saturates the above inequality and gives exact values to \( \alpha \) and \( \beta \).

### 2.4. The Fourfold BPS Scaling Limit

Our main goal is now to solve the coupled differential equations \(^{[17]-[19]} \). Prasad, Sommerfeld, and Bogomolny \(^{[26]-[27]} \) managed to find the exact solution by taking the parameter limit, which simplifies the differential equations. The multiple scaling limit is taken so that all the parameters of the model tend to zero with some combinations of the parameter remaining finite. The combinations are taken so that the vacuum solutions stay finite in this limit. Inspired by this, we will take here a fourfold scaling limit
\[
g, m_1, m_2, \mu \to 0, \quad \frac{m_1}{g} < \infty, \quad \frac{\mu}{g} < \infty, \quad \frac{\mu^2}{m_2^2} < \infty. \quad (30)
\]
This will ensure that the vacuum solutions equation \(^{[11]} \) stays finite, but crucially the curly bracket parts
in equations (18) and (19) vanish. There is a physical motivation for this limit in which the mass ratio of the Higgs and gauge mass are taken to be zero (i.e. \( m_{\text{Higgs}} < \ll m_g \)) as described in [29]. We will see in the next section that the same type of behaviour is present in our model, hence justifying equation (30). The resulting set of differential equations, after Ansatz as given in [26, 27]

\[ \frac{d}{dr} \alpha = 0, \quad \frac{d}{dr} \beta = \pm \frac{c_2 c_3 \mu^2}{m_2^2}, \]

with the asymptotic values of equations (31)-(33)

\[ \nu \equiv \frac{evr}{\sinh (evr)}; \]

\[ h_1(r) = -\alpha f(r), \]

\[ h_2(r) = -\beta f(r), \]

where \( \alpha, \beta \in \mathbb{R} \) were introduced in section 2.3 and \( f(r) \equiv \{ v \coth (evr) - \frac{1}{er} \} \). One can check that this Ansatz indeed satisfies differential equations equation (17) - (19) in the BPS limit. We have decided to put a prefactor \( \alpha \) and \( \beta \) in front of equations (32) and (33) to satisfy the differential equation (17). Note that if we take \( \alpha = 1 \), we get exactly the same as given in [26, 27], which is known to satisfy the first-order differential equation called the Bogomolny equation \( B_t - D_t \phi = 0 \). The Ansatz (31-33) only differs from the ones given in [26, 27] by the prefactors \( \alpha \) and \( \beta \), and therefore our Ansatz should satisfy the Bogomolny equation with the appropriate scaling to cancel the prefactor in equations (32) and (33)

\[ B_t^\pm + \frac{1}{\alpha} (D_t \phi_1)^b = 0, \]

\[ B_t^\pm + \frac{1}{\beta} (D_t \phi_2)^b = 0, \]

where \( \phi_\pm \equiv h_\pm(r) e^{\pm}. \) If we compare these equations to the terms appearing in the energy of the monopole equation (22), then we can saturate the inequality in equation (29) by

\[ E[\phi_1, \phi_2] = \frac{\pm 8 \pi n R}{e} \left( \alpha + \beta \frac{c_2 c_3 \mu^2}{m_2^2} \right), \]

where upper and lower signs correspond to the vacuum solutions equation (11), taking the square root. We can calculate the explicit forms of \( \alpha \) and \( \beta \) by comparing the asymptotic conditions in equation (15)

\[ \lim_{r \to \infty} h_1^\pm = h_0^\pm = \pm R, \]

\[ \lim_{r \to \infty} h_2^\pm = h_0^\pm = \mp \frac{c_2 c_3 \mu^2}{m_2^2} R, \]

with the asymptotic values of equations (31)-33

\[ \lim_{r \to \infty} u(r) = 0, \quad \lim_{r \to \infty} h_1^\pm (r) = -\alpha v, \]

\[ \lim_{r \to \infty} h_2^\pm (r) = -\beta v. \]

By Derrick's scaling argument, the two asymptotic values (37) and (38) should match, resulting in algebraic equations for \( \alpha \) and \( \beta \). Using \( \alpha^2 - \beta^2 = 1 \) and assuming \( m_2^2 \geq \mu^2 \), we find the four set of real solutions

\[ \alpha = \mp (\pm) \frac{m_2^2}{l}, \quad \nu = (\pm) \frac{R l}{m_2^2}, \quad \beta = \pm (\pm) \frac{c_2 c_3 \mu^2}{l}, \]

where \( l = \sqrt{m_2^2 - \mu^2} \). The plus-minus signs in the brackets correspond to the two possible solutions to the algebraic equation \( \alpha^2 - \beta^2 = 1 \). These need to be distinguished from the upper and lower signs of \( \alpha \) and \( \beta \), which correspond to the vacuums solutions (11). Inserting the explicit values of \( \alpha \) and \( \beta \) to the energy equation (36) we find

\[ E[\phi_1, \phi_2] \equiv (\pm) \frac{8 \pi n R}{em_2^2} \left( -\frac{m_1^2 + 2}{l} \right), \]

with corresponding solutions

\[ h_1^\pm (r) = (\pm) \frac{m_1^2}{l} \left( \frac{R l}{m_2^2} \coth \left( \frac{R l}{m_2^2} \right) - \frac{1}{er} \right), \]

\[ h_2^\pm (r) = (\mp) \frac{c_2 c_3 \mu^2}{l} \left( \frac{R l}{m_2^2} \coth \left( \frac{R l}{m_2^2} \right) - \frac{1}{er} \right). \]

It is crucial to note that although it seems like there are two monopole solutions \( \{ h_1^+ , h_2^+ \} \), the two solutions are related non-trivially in their asymptotic limit by the constraint \( \lim_{r \to \infty} h_2^+ = (c_2 c_3 \mu^2/m_2) \lim_{r \to \infty} h_1^+ \) given in equation (10). For example, one can not choose \( \{ h_1^-, h_2^- \} \) as a solution as this will break the asymptotic constraint.

The solution (41) can be constrained further by imposing that the energy (40) is real and positive.

\[ E[\phi_1, \phi_2] > 0 \implies (\pm) \frac{8 \pi n R}{em_2^2} l \implies (\pm) n > 0. \]

Therefore we can ensure positive energy if \( (\pm) = \text{sign}(n) \). The final form of the monopole solution with positive energy are

\[ h_1^\pm (r) = (\pm) \text{sign}(n) \frac{m_1^2}{l} \left( \frac{R l}{m_2^2} \coth \left( \frac{R l}{m_2^2} \right) - \frac{1}{er} \right), \]

\[ h_2^\pm (r) = (\mp) \text{sign}(n) \frac{c_2 c_3 \mu^2}{l} \left( \frac{R l}{m_2^2} \coth \left( \frac{R l}{m_2^2} \right) - \frac{1}{er} \right). \]

with energy \( E = 8n \pi l R/em_2^2 \). We conclude this subsection by observing that the above solution depends on the parameter \( c_3 \), which takes value \( \{-1, 1\} \) depending on the choice of the similarity transformation. Choosing a different values of \( c_3 \) also result in a different asymptotic values (37), meaning solutions for \( c_3 = 1 \) and \( c_3 = -1 \) are topologically different. Since the energy is independent of \( c_3 \), two distinct solutions share the same energy. Respecting one of the main features of similarity transformation, which is to preserve the energy of the transformed Hamiltonian.

In the next section, we will investigate in detail how the solution changes and a new CPT symmetry emerges by changing the parameter values.
3. RESULTS AND DISCUSSION

This section will investigate the behaviour of solutions in different regimes of the parameter spaces. We will compare the physical regions of gauge particles, Higgs particles and monopoles found in the previous section. We will see that the two regions coincide, but the solutions in different regions possess different CPT symmetries. Different symmetries of solutions in different regions are not coincident, but the solutions in different regions possess different \( K \) connected region beyond \( m_1^2 \). One may notice that when \( c_2 = 1 \), requiring positive mass \( m_0^2 > 0 \), implies that \( \mu^2 - m_0^2 > 0 \). This means the quantity \( l = \sqrt{m_0^2 - \mu^2} \) is purely imaginary. One may then discard this region as unphysical. However, we will see in the next section that there is a disconnected region beyond \( \mu^2 - m_0^2 \), which admits real energy because \( R \) also becomes purely complex. This is not coincident, and in fact, we will see an emerging new CPT symmetry for the monopoles.

In the rest of the section, we will exclusively focus on the monopole and gauge masses. The main message of this section is the emerging symmetry responsible for the real value of the monopole masses. The requirement to make the whole theory physical demands also to consider the intersection of the physical regions between monopole masses and Higgs masses. As an example, we plot all the masses of the theory in Figure 1.

As one can see, intersection points of the physical regions of Higgs masses and monopole/gauge masses are non-trivial. In fact, they are bounded by two types of exceptional points. The first type is when two masses of Higgs particles coincide and form a complex conjugate pair. Such a point is known as an exceptional point where the mass matrix is non-diagonalisable, and the corresponding eigenvectors coincide. The second type is when the gauge and the monopole masses vanish. Interestingly, this is where one of the Higgs masses also vanish. Since the mass matrix already has a zero eigenvalue, as the result of the spontaneous symmetry breaking, it seems the number of massless fields is increased. However, at this point, the mass matrix is also non-diagonalisable. Therefore one cannot diagonalise the Hamiltonian to identify the field which corresponds to the extra massless fundamental field. Therefore this point is also an exceptional point. However, the eigenvalues do not become complex conjugate pairs beyond this point, and as one can see from Figure 1 that one of the mass square \( m_0^2 \) become negative, and gauge and monopole masses become complex but with no conjugate pair. We dub such a point as zero exceptional point to distinguish from the standard exceptional point.

3.2. CHANGE IN CPT SYMMETRY AND COMPLEX MONOPOLE SOLUTION

We begin by introducing the useful quantities \( m_1^2/g \equiv X, \mu^2/g \equiv Y, \mu^2/m_0^2 \equiv Z \). The gauge mass, monopole mass and monopole solutions can be rewritten in terms of these quantities

\[
m_g = eR\sqrt{1 - Z^2}, \quad m_{\text{mono}} = \frac{8|\mu|R}{e}\sqrt{1 - Z^2},
\]
and two masses coincide when the point where the vacuum manifold vanishes. There-
the previous section. The upper bounds correspond to
the Hamiltonian is non-diagonalisable, as discussed in
the introduction hold. We will specify below the CPT
symmetry responsible for the real value of the energy.
Note that the profile function \( h_2 \) only differ from \( h_1 \)
by some factor in front. Therefore we omitted it from
the plot.

Another physical region is when \( c_1 = -c_2 = -1 \).
The monopole and gauge masses for this case is plotted
in Figure 4. We observe almost an identical plot
from the Figure 3 but with real and imaginary parts
swapped. The profile functions also respect these
changes as regions 1 and 3 no longer have a definite
asymptotic value. The boundaries are unchanged, as
one can see from the Figure 4.

Finally, there is an interesting parameter point \( X = Y \)
where region 2 vanishes (see Figure 5). The two
boundaries \( Z^2 = 1 \) and \( c_2 Y + c_1 X = 0 \) coincide
when \( X = Y \) and the zero exceptional point no longer
exists because the spontaneous symmetry breaking
does not occur in this case.

Next, let us explain the real value of the energies in
different regions. First, to realise the conditions 1-3,
stated in the introduction, we require the following

\[
h_1^\mp(r) = \frac{\text{sign}(n)}{\sqrt{1 - Z^2}} \left[ R\sqrt{1 - Z^2\coth(\hat{r})} - \frac{1}{er} \right],
\]

where \( R^2 = 4(c_2 Y + c_1 X) \) and \( \hat{r} = eR\sqrt{1 - Z^2}r \).
The monopole masses are plotted against the gauge
mass for fixed parameters with \( n \in \{1, 2, 3, 4\} \) in
Figure 2 with weak and strong couplings \( e = 2, e = 10 \). Notice that the gauge mass is smaller than any of
the monopole masses for weak coupling, but when \( e \) is large enough, some of the monopole masses can
become smaller than the gauge mass. This is clear by
inspecting the monopole, and gauge mass in equation
(46) and two masses coincide when \( e = \sqrt{8/n|\pi|} \). Note
that \( n = 0 \) is not a monopole mass as it corresponds
to the solution with zero winding number, which is
topologically equivalent to the trivial solution.

From Figure 2 we also observe disconnected regions
where both monopole and gauge masses become real
to purely complex. A more detailed plot of this is
shown in Figure 3. Region 2 is bounded by two points
with lower bound \( \mu^2/n_2^2 = 1 \) corresponding to the
zero exceptional point where the vacuum manifolds
stay finite (i.e. spontaneous symmetry breaking occur).
However, the Higgs mechanism fails because
the Hamiltonian is non-diagonalisable, as discussed in
the previous section. The upper bounds correspond to
the point where the vacuum manifold vanishes. Therefore,
the spontaneous symmetry breaking does not occur,
implies that the gauge fields do not acquire

\[
h_2^\mp(r) = \frac{\text{sign}(n)c_2 Y Z}{\sqrt{1 - Z^2}} \left[ R\sqrt{1 - Z^2\coth(\hat{r})} - \frac{1}{er} \right],
\]

a mass through the Higgs mechanism, resulting in
a massless gauge field. Most crucially, an interesting
region (denoted by region 3 in Figure 3) reappears
as one increases the value of \( Z \). The profile function
in region 3 is purely complex, which signals that this
may lead to complex energies. However, as one can
see from Figure 3, the energy is real. The reason for
the real energy is that the conditions stated in the
introduction hold. We will specify below the CPT
symmetry responsible for the real value of the energy.

Note that the profile function \( h_2 \) only differ from \( h_1 \)
by some factor in front. Therefore we omitted it from
the plot.

![Figure 2](image1.png)

**Figure 2.** Monopole and gauge masses plotted for \( X = 1, Y = 0.8, e = 2, c_1 = -c_2 = 1 \). The solid line represents the real part, and the dotted line represents the imaginary part of the masses.

![Figure 3](image2.png)

**Figure 3.** Both panels are plotted for \( X = 1, Y = 0.8, n = 1, e = 2 \). The solid line represents the real part, and the dotted line represents the imaginary part of the masses. Panel (a) shows the monopole and gauge masses against \( Z \geq 0 \), with vertical lines indicating the location of the boundaries of three regions. Panel (b) shows three profile function \( h_1(r) \) defined on each region indicated in panel (a).
Figure 4. Both panels are plotted for $X = 1, Y = 1, n = 1, e = 2$. The solid line represents the real part, and the dotted line represents the imaginary part of the masses.

Figure 5. Both panels are plotted for $X = 1, Y = 1, n = 1, e = 2$. The solid line represents the real part, and the dotted line represents the imaginary part of the masses.

transformations

\[
\begin{align*}
h_2^\pm(r) &\rightarrow -h_2^\pm(r), \
h_1^\pm(r) &\rightarrow h_1^\pm(r)
\end{align*}
\]

in region 1

No symmetry

in region 2.

\[
\begin{align*}
h_2^\pm(r) &\rightarrow -\left(h_2^\pm(r)\right)^*, \
h_1^\pm(r) &\rightarrow \left(h_1^\pm(r)\right)^*
\end{align*}
\]

in region 3

By using the explicit forms of the solutions (46) and (47), we can show that the above transformations satisfy condition 2 stated in the introduction, in regions 1

\[
\begin{align*}
h_2^\pm(r) &\rightarrow -h_2^\pm(r) = h_2^\pm(r), \
h_1^\pm(r) &\rightarrow h_1^\pm(r),
\end{align*}
\]

and in region 3

\[
\begin{align*}
h_2^\pm(r) &\rightarrow -\left(h_2^\pm(r)\right)^* = h_2^\pm, \
h_1^\pm(r) &\rightarrow \left(h_1^\pm(r)\right)^* = h_1^\pm.
\end{align*}
\]

Notice that in regions 1 and 3, the $\mathcal{CP}$ relates two distinct solutions in two different ways. For example, $h_2^\pm$ is mapped to $h_2^\pm$ in region 1, but it is mapped to itself in region 3.

Finally, the condition 3 stated in the introduction is satisfied because the energy does not depend on the $\pm$ signs of the solutions. This explains the real energies of complex monopoles in region 3 and complex energy in region 2. Indeed, we observe the predicted behaviour in Figure 3. Region 2 is a hard barrier between two $\mathcal{CP}$ symmetric regions where solutions are either real or purely imaginary. The same analysis can be carried out in the other physical region $c_1 = -c_2 = -1$ where the symmetry is now

\[
\begin{align*}
h_2^\pm(r) &\rightarrow -h_2^\pm(r)^*, \
h_1^\pm(r) &\rightarrow (h_1^\pm(r))^*
\end{align*}
\]

in region 2.

We have observed that one can find a well-defined monopole solution in two disconnected regions. However, in the full theory where we include the Higgs particles, it is only one of the regions which are considered physical. This is because the Higgs mass $m_0^2$ is either positive or negative depending on which side of $Z^2 = 1$ it is defined. Because two disconnected regions are defined on either side of the zero exceptional point $Z^2 = 1$, the full physical region restricts one from moving region 1 to region 3 by changing $Z$. This is most clearly seen in Figure 1 where the plot of $m_0^2$ (green line) becomes negative beyond the zero exceptional point. This may imply that the purely complex monopole solution we observed is not a possible solution of the theory. However, the purely complex solution can exist in the full physical region. An example of this is shown in the Figure 6 where we observe that the profile function $h_1$ (therefore $h_2$) is purely complex, and the Higgs masses, gauge mass are all real and positive.

4. Conclusions

We have found the t’Hooft-Polyakov monopole solution in the non-Hermitian theory by drawing an
analogue from the standard procedure in the Hermitian theory. The monopole masses were plotted with the massive gauge and Higgs masses, where the physical region of the monopole masses coincided with that of the gauge mass. It was also observed that there are two distinct physical regions bounded by the zero exceptional point and the parameter limit where the vacuum manifold becomes trivial. The profile function (radial part of the monopole solution) is plotted in Figures 3, 4, 5, where it is real and purely complex in regions 1 and 3, respectively. Incidentally, the \( CPT \) symmetries of the solution are different in regions 1 and 3.
