Abstract
A system of ordinary differential equations describing the interaction of a fast and a slow particle is studied, where the interaction potential $U$ depends on a small parameter $\varepsilon$. The parameter $\varepsilon$ can be interpreted as the mass ratio of the two particles. For positive $\varepsilon$, the equations of motion are Hamiltonian. It is known [6] that the homogenised limit $\varepsilon \to 0$ results again in a Hamiltonian system with homogenised potential $U_{\text{hom}}$. In this article, we are interested in the situation where $\varepsilon$ is small but positive. In the first part of this work, we rigorously derive the second-order correction to the homogenised degrees of freedom, notably for the slow particle $y_\varepsilon = y_0 + \varepsilon^2(y_2 + [y_2]_\varepsilon)$. In the second part, we give the resulting asymptotic expansion of the energy associated with the fast particle $E^\varepsilon_2 = E^{\varepsilon}_2 + \varepsilon^2(E^{\varepsilon}_2 + [E^{\varepsilon}_2]_\varepsilon)$, a thermodynamic interpretation. In particular, we note that to leading-order $\varepsilon \to 0$, the dynamics of the fast particle can be identified as an adiabatic process with constant entropy, $dS_0 = 0$. This limit $\varepsilon \to 0$ is characterised by an energy relation that describes equilibrium thermodynamic processes, $dE^\varepsilon_2 = F_0 dy_0 + T_0 dS_0 = F_0 dy_0$, where $T_0$ and $F_0$ are the leading-order temperature and external force terms respectively. In contrast, we find that to second-order $\varepsilon^2$, a non-constant entropy emerges, $dS_2 \neq 0$, effectively describing a non-adiabatic process. Remarkably, this process satisfies on average (in the weak∗ limit) a similar thermodynamic energy relation, i.e., $dE^\varepsilon_2 = F_0 dy_2 + T_0 dS_2$.

1 Introduction

Fast-slow Hamiltonian systems constitute a class of mechanical systems in which the interacting degrees of freedom evolve on different time-scales. As such, they play a fundamental role in the description of molecular processes. A motivational example for such a molecular process is the motion of a lightweight solvent molecule in a solvent, where the typical fast evolution of the light solvent molecules is in stark contrast to the slow conformal motion of the heavy solvent molecule. To analyse this molecular process, one heavily relies on accurate computer simulations. Typical molecular dynamic simulations update the position of each degree of freedom, according to Newton’s law of motion, iteratively for each time-step. In practice, however, these simulations become quickly infeasible because of the large number of solvent molecules that constitute the system, which can easily range in the tens of thousands, and the small time-step that is essential to capture their fast motion accurately. In light of these computational problems, there is a strong need for mathematical formalisms that establish effective and computable approximate models for the given fast-slow Hamiltonian system.

A fundamental strategy in the derivation of such mathematical formalisms is the introduction of a scale-parameter $\varepsilon$ into the model (representing, for instance, the mass ratio). One can then approach the fast-slow system by considering the limit $\varepsilon \to 0$ and thus derive a homogenised model that is, in some sense, oblivious to the small-scale motion in the system. Although computationally more favourable, this homogenised model must be understood as an idealised approximation to the originally given system only. To approximate natural phenomena more realistically, however, an analysis away from the limit $\varepsilon \to 0$ is necessary.

In this article, we study a fast-slow Hamiltonian system away from the limit $\varepsilon \to 0$, by expanding it to second-order in $\varepsilon$. For small but positive $\varepsilon > 0$, the most dominant small-scale motions enter again into the finer approximate model. To address the related computational problems, we explore a new approach by considering the fast-slow dynamics as a thermodynamic process in which the fast degrees of freedom are

∗M.Klar@bath.ac.uk
†K.Matthies@bath.ac.uk
‡jz@ma.tum.de
described by a notion of temperature and entropy. More precisely, we study a simple fast-slow Hamiltonian system with four degrees of freedom. By keeping a molecular dynamic picture in mind, we can regard it as a system of one fast particle that is coupled to one slow particle. We assume that their interaction is governed by the Lagrangian \( L \) below, for which the homogenised limit \( \varepsilon \to 0 \) has been derived by Bornemann [6]. We point out that the corresponding homogenised Lagrangian describes the average dynamics of the slow particle only; yet, the fast particle’s effect enters as a computable constant into the homogenised limit. This constant results from a homogenised evolution that can be interpreted, from a thermodynamic perspective (as already pointed out in [12]), as an idealised thermodynamic process, i.e., an adiabatic process with constant entropy which satisfies the thermodynamic relation \( \frac{dU}{dt} = 0 \). Remarkably, we show in this work, that a higher-order homogenisation approach leads to a more general thermodynamic description of the system. Specifically, continuing the work of Bornemann, we rigorously derive the second-order expansion in \( \varepsilon \) of the system’s dynamics which can be formulated as a second-order two-scale expansion. It then turns out that a nonconstant entropy appears at second-order which satisfies the thermodynamic relation \( \frac{dU}{dt} = 0 \).

Our model problem is a simple fast-slow Hamiltonian system which falls into the class of mechanical systems described by the Lagrangian

\[
\mathcal{L}_\varepsilon(x, \dot{x}) = \frac{1}{2} \langle \dot{x}, \dot{x} \rangle - W_\varepsilon(x), \quad x \in T_x M, \tag{1}
\]

where \( M \) is the configuration space, taken to be a smooth Riemannian manifold with metric \( \langle \cdot, \cdot \rangle \) and \( W_\varepsilon : M \to \mathbb{R} \) is a smooth potential function of the form

\[
W_\varepsilon(x) = V(x) + \varepsilon^{-2} U(x). \tag{2}
\]

Taking the limit \( \varepsilon \to 0 \), the above system converges to a system with a strong constraining force (see, e.g., [13]). More precisely, if \( U \) is non-negative and coercive, the second term in \( W_\varepsilon \) constrains the motion in the limit \( \varepsilon \to 0 \) to a critical submanifold \( N = U^{-1}(0) \subset M \), which characterises the large-scale evolution of the system. This limit system, i.e., the homogenised limit, can be seen as the lowest order approximation in \( \varepsilon \) of the original system. To derive a more accurate approximation of the mechanical system, which above all includes the most dominant small-scale interactions into the approximate model, a detailed analysis of the motion in a small neighbourhood around \( N \) is necessary. For this reason, we derive in the first part of this work a higher-order approximation of system (1) for small but non-zero \( \varepsilon \). Since a more accurate approximation of the mechanical system increases the computational complexity, we analyse subsequently the resulting motion in the vicinity of \( N \) from a thermodynamic point of view, with the intention of deriving a mathematical formalism that can improve current numerical integration schemes.

We recall existing results for system (1) in the limit \( \varepsilon \to 0 \), established by Bornemann [6] in a very elegant framework. In short, if the initial data is chosen such that the total energy is uniformly bounded as \( \varepsilon \to 0 \), then the solutions \( x_\varepsilon \) of the equations of motion oscillate on a time-scale of order \( \mathcal{O}(\varepsilon) \) within a distance of order \( \mathcal{O}(\varepsilon) \) to the submanifold \( N \). Moreover, the sequence of solutions \( x_\varepsilon \) converges uniformly to a function \( x_0 \) of time, taking values in \( N \), where \( x_0 \) is the unique solution to the Euler-Lagrange equations corresponding to the homogenised Lagrangian

\[
\mathcal{L}_{\text{hom}}(x, \dot{x}) = \frac{1}{2} \langle \dot{x}, \dot{x} \rangle - V(x) - U_{\text{hom}}(x), \quad x \in T_x N, \tag{2}
\]

where \( U_{\text{hom}} \) can be derived from the Hessian of the constraining potential \( U \). We point out that the limit evolution is in general not the original Hamiltonian motion constrained to the submanifold \( N \); instead, for generic initial data the small-scale oscillatory motion in the neighbourhood of \( N \) gives rise to information which persists in the limit \( \varepsilon \to 0 \). In other words, the limit Hamiltonian depends on the structure of \( U \) near \( N \).

The interaction of a fast and a slow particle is one of the simplest models falling into the class of Hamiltonian mechanical systems described by (1); here \( \varepsilon \) can be interpreted as the stiffness of the underlying potential resulting in the two disparate time-scales. To visualise this system in the context of (1), we describe the fast particle by \( z \) and the slow particle by \( y \). The interaction can then be pictured in \( z = (y, z) \) coordinates as a motion governed by a potential which is flat in direction of \( y \) and steep in direction of \( z \), taking without loss of generality the minimum of this potential as 0. A motion starting on the zero level set (the submanifold \( N \)) with non-vanishing velocity component in direction \( z \) will then oscillate rapidly around \( N \). The homogenised limit (2) then describes the motion in the limit \( \varepsilon \to 0 \).

The main motivation for studying a simple fast-slow Hamiltonian system of two particles is, that it is the simplest possible system that can potentially exhibit thermodynamic effects. Indeed, one of the core assumptions of thermodynamics is that the system under consideration has a clear separation of scales (such as conformal motion described by elasticity combined with fast oscillations described by temperature). It is not essential that the number of particles is large or infinite. Indeed, the physicist Paul Hertz developed a thermodynamic theory [10] for Hamiltonian systems under a slow external perturbation. Specifically, he introduced an entropy, using a notion of temperature as developed by Boltzmann. The book by Berdichevsky [5] gives an excellent introduction to this theory.
If one applies the theory of Hertz to our prototypical two-dimensional system \([3]\), one can interpret the dynamics associated with \(z\) as a fast subsystem that is slowly being perturbed by the motion resulting from the slow subsystem governed by \(y\). On an energy level, this is reflected by the total energy \(E_c(y, \dot{y}, z, \dot{z})\), which can be decomposed into the fast subsystem’s energy \(E^f_c(z, \dot{z}; y)\) and the slow subsystem’s energy \(E^s_c = E_c - E^f_c\), respectively. Hertz’ theory then allows to describe the fast subsystem from a thermodynamic point of view, using a notion of temperature \(T_c\), entropy \(S_c\) and external force \(F_c\) (the force that \(y\) exerts on \(z\)). With \(\varepsilon\) as a scale-parameter, the model allows for a detailed analysis of the system on different scales in time and space. In the first part of this article, we rigorously derive a higher order asymptotic expansion beyond the limit system \([2]\). For instance, the expansion of the slow particle takes the form \(y = y_0 + \varepsilon^2(y_2 + [y_2])\), where \(y_2\) is the (slow) averaged and \([y_2]\) is the rapidly oscillating component of the second-order expansion. In conjunction with Hertz’ theory, similarly apply, in the second part of this article, the asymptotic expansion to the fast subsystem’s energy and the thermodynamic quantities, i.e., \(E^f_c = E^f_{0c} + \varepsilon E^f_{1c} + \varepsilon^2 E^f_{2c}\), \(T_c = T_0 + O(\varepsilon)\), \(S_c = S_0 + \varepsilon S_1 + \varepsilon^2 S_2\) and \(F_c = F_0 + O(\varepsilon)\). By analysing the limit \(\varepsilon \to 0\) one finds, that the entropy associated with the fast subsystem remains constant during the motion, i.e., \(dS_2 = 0\). Hence, in the limit of infinite separation of time-scales, the evolution of the fast subsystem is adiabatic, which is by definition an idealised thermodynamic process with constant entropy \([23]\) Chapter 1.4]. This is above all reflected in the energy relation which describes equilibrium thermodynamic processes, i.e.,

\[
dE^f_{1c} = F_0dy_0 + T_0dS_0 = F_0dy_0. \tag{3}
\]

Furthermore, the model allows for a detailed thermodynamic analysis away from the limit \(\varepsilon \to 0\). We show in this article that on scale \(\varepsilon^2\), a non-constant entropy appears, \(dS_2 \neq 0\), which satisfies on average (in the weak* limit) a similar thermodynamic energy relation, i.e.,

\[
dE^f_{2c} = F_0d\dot{y}_2 + T_0d\dot{S}_2. \tag{4}
\]

Hence in this very simple situation, the system is described to leading-order by an effective energy (which is not the naïve limit, as shown in \([6]\) with constant entropy, while a non-constant entropy appears to second-order.

We remark that the thermodynamic interpretation uses the formulas developed by Hertz. The derivation of the second-order correction is rigorous, using methods of weak convergence. The method of weak convergence is an effective tool for averaging oscillatory behaviour in partial differential equations. The macro-scale dynamics (effective dynamics for \(y\)) can be viewed as the averaged motion of the mechanical system. Various other asymptotic and averaging methods have been developed to describe situations when singular perturbations cause rapid, micro-scale fluctuations in the solution. Often an asymptotic description — involving an explicit ansatz for the oscillatory part of the solution — is necessary to analyse the dynamics for \(\varepsilon > 0\). Some examples are provided by the perturbation theory of integrable Hamiltonian systems \([3]\), the WBK method \([13]\) or multiple-scale-asymptotics \([4]\); modern presentations for several of these approaches include \([11]\) and \([16]\).

While we have the simplest model for atomistic interaction in mind, the setting is potentially more broadly applicable; notably in cases where the homogenisation theory outlined above and related work as in \([17]\) finds relevance, such as the problem of deriving the guiding centre motion is plasma physics \([7]\), the elimination of fast molecular vibration in classical molecular dynamics \([19]\) or in the description of quantum-classical models in quantum-chemistry \([6]\). This homogenisation approach was recently used in \([12]\) to coarse-grain the coupled thermoelastic behaviour of solids from the atomistic scale.

### 1.1 The model problem

For a small scale-parameter \(0 < \varepsilon < \varepsilon_0\), we study a family of mechanical systems described by the Lagrangian

\[
\mathcal{L}_\varepsilon(y, z, \dot{y}, \dot{z}) = \frac{1}{2}\dot{y}^2 + \frac{1}{2}\dot{z}^2 - \frac{1}{2}\varepsilon^{-2}\omega^2(y)z^2, \tag{5}
\]

on the two-dimensional Euclidean configuration space \(M = \mathbb{R}^2\). This system is a simplified version of the model problem introduced in \([6]\) §1.2.1]. The corresponding Newtonian equations of motion take the form

\[
\ddot{y}_c = -\varepsilon^{-2}\omega(y)\omega'(y)z_c^2, \tag{6a}
\]

\[
\ddot{z}_c = -\varepsilon^{-2}\omega^2(y)z_c. \tag{6b}
\]

We assume that \(\omega \in C^\infty(\mathbb{R})\) is a uniformly positive function, i.e., there is a constant \(\omega_* > 0\) such that

\[
\omega(y) \geq \omega_*, \quad \text{for all } y \in \mathbb{R}, \tag{7}
\]

and consider \(\varepsilon\)-independent initial values,

\[
y_c(0) = y_*, \quad \dot{y}_c(0) = p_*, \quad z_c(0) = 0, \quad \dot{z}_c(0) = u_. \tag{8}
\]
Notice that the particular choice \( z_\epsilon(0) = 0 \) makes the conserved energy \( E_\epsilon \) of the system independent of \( \epsilon \),

\[
E_\epsilon = \frac{1}{2} \dot{y}_\epsilon^2 + \frac{1}{4} \dot{z}_\epsilon^2 + \frac{1}{2} \epsilon^{-2} \omega^2(y_\epsilon) z_\epsilon^2 = \frac{1}{2} \dot{p}_\epsilon^2 + \frac{1}{2} u_\epsilon^2 = E_* .
\] (9)

We are primarily interested in the time evolution of the slow degree of freedom \( y_\epsilon \). The following theorem [6, Theorem 1, Chapter I] shows that \( y_\epsilon \) converges in the limit \( \epsilon \to 0 \) to a function \( y_0 \) which is given as the solution to a second-order differential equation. The constant \( \theta_* \) in the effective potential is of the form \( \theta_* = u_*^2/2\omega(y_\epsilon) \), with \( y_\epsilon \) and \( u_* \) as in (8). We will later see that \( \theta_* \) is proportional to the action of the fast subsystem in the limit \( \epsilon \to 0 \). As a consequence, some information of the fast subsystem is retained in the slow evolution of \( y_\epsilon \).

**Theorem 1.1 (Bornemann, [6]).** Let \( y_0 \) be the solution to the second-order differential equation

\[
\dot{y}_0 = -\theta_* \omega'(y_0),
\]

with initial values \( y_0(0) = y_* \), \( \dot{y}_0(0) = p_* \). Then, for every finite time interval \([0, T]\), one obtains the strong convergence

\[
y_\epsilon \to y_0 \quad \text{in} \quad C^1([0, T])
\]

and the weak* convergences \( \epsilon^{-1} z_\epsilon \overset{\text{w*}}{\to} 0 \) and \( \dot{z}_\epsilon \overset{\text{w*}}{\to} 0 \) in \( L^\infty([0, T]) \).

We extend the theory developed in [6] by deriving rigorously the second-order asymptotic expansion for the solution of the equations of motion (6) and interpret the corresponding expansion of the energy (9) from a thermodynamic point of view. A crucial step in the derivation of these expansions is the introduction of action-angle variables for the rapidly oscillating degree of freedom \((z_\epsilon, \dot{z}_\epsilon) \mapsto (\theta_\epsilon, \phi_\epsilon)\), which also involves a transformation of the generalised momentum \( \dot{y}_\epsilon \mapsto p_\epsilon \) to preserve the symplectic structure on the phase-space as a whole.

### 1.2 Main results

The main results in this work can be stated as follows:

1. There is a second-order asymptotic expansion of the variables \( y_\epsilon, p_\epsilon, \theta_\epsilon, \phi_\epsilon \) introduced in the previous paragraph and defined precisely in Section 3, this expansion is of the form

\[
y_\epsilon = y_0 + \epsilon [\dot{y}_1]^\epsilon + \epsilon^2 [\dot{y}_2]^\epsilon + \epsilon^3 \dot{y}_3, \quad p_\epsilon = p_0 + \epsilon [\dot{p}_1]^\epsilon + \epsilon^2 [\dot{p}_2]^\epsilon + \epsilon^3 \dot{p}_3, \quad 
\theta_\epsilon = \theta_* + \epsilon [\dot{\theta}_1]^\epsilon + \epsilon^2 [\dot{\theta}_2]^\epsilon + \epsilon^3 \dot{\theta}_3, 
\phi_\epsilon = \phi_0 + \epsilon [\dot{\phi}_1]^\epsilon + \epsilon^2 [\dot{\phi}_2]^\epsilon + \epsilon^3 \dot{\phi}_3,
\]

where for \( i \in \{1, 2\} \),

\[
[\dot{y}_i] := \dot{y}_i + [y_i]^\epsilon \overset{\text{w*}}{\to} \dot{y}_i \quad \text{in} \quad L^\infty((0, T)), \quad y_3 \to 0 \quad \text{in} \quad C([0, T]),
\]

\[
[\dot{p}_i] := \dot{p}_i + [p_i]^\epsilon \overset{\text{w*}}{\to} \dot{p}_i \quad \text{in} \quad L^\infty((0, T)), \quad p_3 \to 0 \quad \text{in} \quad C([0, T]),
\]

\[
[\dot{\theta}_i] := \dot{\theta}_i + [\theta_i]^\epsilon \overset{\text{w*}}{\to} \dot{\theta}_i \quad \text{in} \quad L^\infty((0, T)), \quad \theta_3 \to 0 \quad \text{in} \quad C([0, T]),
\]

\[
[\dot{\phi}_i] := \dot{\phi}_i + [\phi_i]^\epsilon \overset{\text{w*}}{\to} \dot{\phi}_i \quad \text{in} \quad L^\infty((0, T)), \quad \phi_3 \to 0 \quad \text{in} \quad C([0, T]).
\]

In other words, for each variable the second-order asymptotic expansion is characterised — to leading-order by the theory developed in [6] (Theorem 1.1) — to \( i \)-th order by a decomposition into a slow term, indicated by an overbar, which constitutes the average motion of the \( i \)-th order expansion, and a fast term, indicated by square brackets, which oscillate rapidly and converge weakly* to zero — and by a residual term, indicated with a subscript three, that converges uniformly to zero. In particular, we show that

\[
[\dot{y}_1]^\epsilon = 0, \quad [\dot{p}_1]^\epsilon = 0, \quad [\dot{\theta}_1]^\epsilon = [\theta_1]^\epsilon, \quad [\dot{\phi}_1]^\epsilon = 0,
\] (10)

and that \((\bar{\theta}_2, \bar{\dot{\theta}_2}, \bar{\dot{y}_2}, \bar{p}_2)\) is given as the solution to an inhomogeneous linear system of differential equations (Theorem 3.2). Moreover the rapidly oscillating functions \([\dot{\theta}_1]^\epsilon, [\dot{y}_2]^\epsilon, [\dot{p}_2]^\epsilon, [\dot{\theta}_2]^\epsilon\) and \([\dot{\phi}_2]^\epsilon\), are explicitly given in Definition 3.1.

Finally, we show that this expansion can be interpreted as a nonlinear version of a two-scale expansion, which we briefly introduce in Appendix A.

2. Using the framework of Hertz [10], we define a temperature \( T_\epsilon \), an entropy \( S_\epsilon \) and an external force \( F_\epsilon \) for the fast subsystem based on a scaling of space and time of the fast degree of freedom \( z_\epsilon \), such that in the limit \( \epsilon \to 0 \), the system is in thermal equilibrium (see Appendix 3.4). In combination with the
analytic result discussed under [1] we decompose the total energy $E_z$ into the energy associated with the fast particle $E_z^\parallel$ and the residual energy $E_z^\perp = E_z - E_z^\parallel$, and expand, similar as above $E_z^\parallel$, $E_z^\perp$, $T_z$, $S_z$ and $F_z$ into the form

$$
E_z^\parallel = E_0^\parallel + \varepsilon [E_1^\parallel]^\varepsilon + \varepsilon^2 [E_2^\parallel]^\varepsilon + \varepsilon^3 E_3^\perp, \\
E_z^\perp = E_0^\perp + \varepsilon [E_1^\perp]^\varepsilon + \varepsilon^2 [E_2^\perp]^\varepsilon + \varepsilon^3 E_3^\perp, \\
S_z = S_0 + \varepsilon [S_1]^\varepsilon + \varepsilon^2 [S_2]^\varepsilon + \varepsilon^3 S_3, \\
T_z = T_0 + \mathcal{O}(\varepsilon), \\
F_z = F_0 + \mathcal{O}(\varepsilon),
$$

where for $i \in \{1, 2\}$,

$$
[E_i^\perp]^\varepsilon := E_i^\perp + \varepsilon [E_i^\perp]^\varepsilon \xrightarrow[\varepsilon \rightarrow 0]{} E_3^\perp \text{ in } L^\infty((0, T)), \\
[E_i^\parallel]^\varepsilon := E_i^\parallel + \varepsilon [E_i^\parallel]^\varepsilon \xrightarrow[\varepsilon \rightarrow 0]{} E_i^\parallel \text{ in } L^\infty((0, T)), \\
[S_i]^\varepsilon := S_i + \varepsilon [S_i]^\varepsilon \xrightarrow[\varepsilon \rightarrow 0]{} S_i \text{ in } L^\infty((0, T)).
$$

The characterisation of the $i$-th order expansion is similar as above; moreover, it follows from [9] that

$$
E_2 = E_0^\parallel + E_0^\perp = E_*, \quad [E_1^\parallel]^\varepsilon + [E_1^\perp]^\varepsilon = 0, \quad [E_2^\parallel]^\varepsilon + [E_2^\perp]^\varepsilon = 0, \quad E_3^\parallel + E_3^\perp = 0.
$$

In Section 4 we show that

$$
[E_1^\perp]^\varepsilon = [E_1^\parallel]^\varepsilon, \quad [E_1^\parallel]^\varepsilon = [E_1^\parallel]^\varepsilon, \quad [S_1]^\varepsilon = [S_1]^\varepsilon,
$$

and interpret the asymptotic expansion from a thermodynamic point of view. In particular, we show that to leading-order the entropy expression remains constant, i.e., $dS_0 = 0$, and consequently the dynamics can be interpreted as an adiabatic process characterised by an energy relation that defines processes in thermodynamic equilibrium,

$$
dE_0^\parallel = F_0 dy_0 + T_0 dS_0 = F_0 dy_0. \tag{11}
$$

In contrast, we show that the averaged second-order dynamics, i.e., the dynamics in the weak* limit, indicated by an overbar, represents a non-adiabatic process with an averaged non-constant entropy, $d\bar{S}_2 \neq 0$, that similarly as above satisfies relations akin to equilibrium thermodynamics, despite being beyond the limit $\varepsilon \rightarrow 0$,

$$
d\bar{E}_2 = F_0 d\bar{y}_2 + T_0 d\bar{S}_2, \tag{12}
$$

where $\bar{S}_2$ indicates the averaged second-order entropy expression ignoring interactions with its first-order expansion. Finally, we show in Theorem 4.1 that the evolution of $(\bar{y}_2, \bar{p}_2)$ is governed by equations which resemble Hamilton’s canonical equations,

$$
\frac{d\bar{y}_2}{dt} = -\frac{\partial \bar{E}_2}{\partial \bar{p}_2}, \quad \frac{d\bar{p}_2}{dt} = -\frac{\partial \bar{E}_2}{\partial \bar{y}_2},
$$

for $\bar{E}_2 = \bar{E}_2^\parallel + \bar{E}_2^\perp$, which are complemented by the $\varepsilon$-independent initial values

$$
\bar{y}_2(0) = -[y_2]^\varepsilon(0), \quad \bar{p}_2(0) = -[p_2]^\varepsilon(0).
$$

In summary, Theorem 4.1 shows that the family of mechanical systems (5) converges as $\varepsilon \rightarrow 0$ to a mechanical system, which is again Hamiltonian in nature. Based on our asymptotic expansion result we show that the leading-order entropy expression according to Hertz [10] is constant (cf. equation (11)), and that a non-constant entropy appears in the second-order expansion (cf. equation (12)). We refer to the recent study [12], which inspired our analysis. There, a classic thermodynamic description of the elastodynamics of solids is derived by studying thermoelastic coupling for bars of various lengths, thus explicitly controlling the value of $\varepsilon$. The authors then observe that in the limit $\varepsilon \rightarrow 0$, the dynamics are Hamiltonian, while dissipation occurs for larger values of $\varepsilon$. The study [12] also combines methods of [6] and [10].

Outline of the paper

Section 2 contains preliminary steps for the analysis of the model problem. We introduce action-angle variables for the rapidly oscillating degree of freedom and prove the existence and uniqueness of a solution to the transformed model problem. Section 3 includes the proof of the second-order asymptotic expansion of $y_\varepsilon, p_\varepsilon, \theta_\varepsilon$ and $\phi_\varepsilon$. After deriving the leading-order expansion, we introduce some notation that simplifies the subsequent analysis of the first- and second-order expansion. In Section 4 we introduce the thermodynamic quantities and give their detailed interpretation in the context of the model problem. The second-order expansion can be represented as a nonlinear version of a two-scale expansion, which we introduce in Appendix A. Finally, in Appendix B we describe how the thermodynamic quantities can be derived for the model problem using Hertz’ original method.
2 The model problem in action-angle variables

To analyse the dynamics of \( y_c \) and \( z_c \) for \( 0 < \varepsilon < \varepsilon_0 \), a detailed asymptotic analysis is required. We build on Appendix A, which introduces action-angle variables and uses tools from the perturbation theory of integrable Hamiltonian systems (as presented, for instance, in [3]), to derive the asymptotic behaviour of \( y_c \) and \( z_c \) to first-order. We will expand the results and determine the explicit form of the second-order correction. As in [6], we start by rephrasing the governing perturbed system of Newtonian equations [5]. We denote by \( (\eta, z) \) the canonical momenta corresponding to the positions \( (y_c, z_c) \). Then the equations of motion [6], together with the velocity relations

\[
\dot{y}_c = \eta_c, \quad \dot{z}_c = \zeta_c,
\]

are given by the canonical equations of motion belonging to the energy function

\[
E_c(y_c, \eta, z_c, \zeta_c) = \frac{1}{2} \eta^2 + \frac{1}{2} \zeta^2 + \frac{1}{2} \varepsilon^{-2} \omega^2(y_c) z_c^2.
\]

To take the oscillatory character of \( z_c \) into account, we introduce particular action-angle variables \( (\theta_c, \phi_c) \) for the fast degrees of freedom \( (z_c, \zeta_c) \),

\[
z_c = \varepsilon \sqrt{\frac{2\theta_c}{\omega(y_c)}} \sin(\varepsilon^{-1} \phi_c), \quad \zeta_c = \sqrt{2\theta_c \omega(y_c)} \cos(\varepsilon^{-1} \phi_c).
\]

The transformation \( (z_c, \zeta_c) \rightarrow (\theta_c, \phi_c) \) can be found using the theory of generating functions [2 §48]. For fixed \( y_c \), the transformation is generated by the function

\[
S_0(\theta_c, \phi_c; y_c) = \frac{1}{2} \varepsilon^{-1} \omega(y_c) z_c^2 \cot(\varepsilon^{-1} \phi_c),
\]

via \( \zeta_c = \partial S_0 / \partial z_c \) and \( \theta_c = -\partial S_0 / \partial \phi_c \). It turns out, however, that this transformation is symplectic only for fixed \( y_c \). Therefore, we now modify the position \( y_c \) or the momentum \( \eta_c \). The extended generating function \( S(y_c, p_c, z_c, \phi_c) = p_c y_c + S_0(\theta_c, \phi_c; y_c) \) does not transform the position variable \( y_c = \partial S / \partial p_c \) but changes the momentum \( \eta_c \) such that the transformation remains symplectic on the phase space as a whole. The missing transformation of the momentum \( \eta_c \) is thus given by

\[
\eta_c = \frac{\partial S}{\partial y_c} = p_c + \varepsilon \frac{\theta_c \omega'(y_c)}{2 \omega(y_c)} \sin(2 \varepsilon^{-1} \phi_c).
\]

By construction, the resulting transformation \( (y_c, \eta_c; z_c, \zeta_c) \rightarrow (y_c, p_c; \phi_c, \theta_c) \) is symplectic on the whole phase space. The energy function [13] transforms to the expression

\[
E_c = \frac{1}{2} p_c^2 + \theta_c \omega(y_c) + \varepsilon \frac{\theta_c p_c \omega'(y_c)}{2 \omega(y_c)} \sin(2 \varepsilon^{-1} \phi_c) + \varepsilon^2 \frac{\theta_c^2 \omega'(y_c)^2}{4 \omega^2(y_c)} \sin^2(2 \varepsilon^{-1} \phi_c).
\]

Thus, by the canonical formalism, the equations of motion take the form

\[
\dot{\phi}_c = \frac{\partial E_c}{\partial \theta_c}, \quad \dot{\theta}_c = -\frac{\partial E_c}{\partial p_c}, \quad \dot{y}_c = \frac{\partial E_c}{\partial \eta_c}, \quad \dot{p}_c = -\frac{\partial E_c}{\partial y_c},
\]

which gives after some calculations

\[
\begin{align*}
\dot{\phi}_c &= \omega(y_c) + \varepsilon \frac{\theta_c p_c \omega'(y_c)}{2 \omega(y_c)} \sin(2 \varepsilon^{-1} \phi_c) + \varepsilon^2 \frac{\theta_c^2 \omega'(y_c)^2}{4 \omega^2(y_c)} \sin^2(2 \varepsilon^{-1} \phi_c), \\
\dot{\theta}_c &= -\frac{\theta_c p_c \omega'(y_c)}{\omega(y_c)} \cos(2 \varepsilon^{-1} \phi_c) - \varepsilon \frac{\theta_c^2 \omega'(y_c)^2}{4 \omega^2(y_c)} \sin(4 \varepsilon^{-1} \phi_c), \\
\dot{y}_c &= p_c + \varepsilon \frac{\theta_c \omega'(y_c)}{2 \omega(y_c)} \sin(2 \varepsilon^{-1} \phi_c), \\
\dot{p}_c &= -\theta_c \omega'(y_c) + \varepsilon \frac{\theta_c p_c \omega'(y_c)^2}{2 \omega^2(y_c)} \sin(2 \varepsilon^{-1} \phi_c) - \varepsilon \frac{\theta_c^2 \omega'(y_c)^2}{2 \omega(y_c)} \sin(2 \varepsilon^{-1} \phi_c) + \varepsilon^2 \frac{\theta_c p_c \omega''(y_c)}{4 \omega^2(y_c)} \sin^2(2 \varepsilon^{-1} \phi_c).
\end{align*}
\]

The initial values, as given in [5], transform to

\[
\phi_c(0) = 0, \quad \theta_c(0) = \theta_*, \quad y_c(0) = y_*, \quad p_c(0) = p_*. \quad (17)
\]
2.1 Existence and uniqueness of a solution to the model problem

Let us denote the right hand side of \( \{16\} \) as \( \mathcal{F}_\varepsilon: \mathbb{R}^4 \to \mathbb{R}^4 \). By assumption, \( \omega \in C^\infty(\mathbb{R}) \) and therefore \( \mathcal{F}_\varepsilon \in C^\infty(\mathbb{R}^4, \mathbb{R}^4) \) for \( 0 < \varepsilon < \varepsilon_0 < \infty \). In particular, \( \mathcal{F}_\varepsilon \) is locally Lipschitz continuous. Hence, by the standard existence and uniqueness theory for ordinary differential equation (see, for example, [20]), there exists a \( 0 < T < \infty \) such that the initial value problem \( \{16\} - \{17\} \) has a unique solution

\[
(\phi_\varepsilon, \theta_\varepsilon, y_\varepsilon, p_\varepsilon) \in C^\infty([0, T], \mathbb{R}^4),
\]

for fixed \( 0 < \varepsilon < \varepsilon_0 \).

3 Second-order asymptotic expansion

In this section, we rigorously derive the second-order asymptotic expansion for \( \phi_\varepsilon, \theta_\varepsilon, y_\varepsilon \) and \( p_\varepsilon \). The equations in \( \{16\} \) are used to derive the leading-order expansions in 3.1, before we reformulate them in 3.2 to derive jointly the first- and second order expansion in 3.3 and 3.4.

3.1 Leading-order expansion

Let us analyse the sequence of solutions \( \{18\} \) for \( \varepsilon \to 0 \). The right-hand side of \( \{16\} \) is oscillatory and has in particular a highly oscillatory leading-order term. As a consequence, the sequences \( \{d\phi_\varepsilon/d\varepsilon\}, \{\theta_\varepsilon\}, \{dy_\varepsilon/d\varepsilon\}, \{dp_\varepsilon/d\varepsilon\} \) are bounded in the space \( C^0([0, T]) \) of uniformly Lipschitz continuous functions, while sequences of higher-order derivatives (in particular \( \{d^2\theta_\varepsilon/d\varepsilon^2\} \), which will require special attention in the later part of this work) become unbounded as \( \varepsilon \to 0 \). It follows from the extended Arzela-Ascoli Theorem [6, Principle 4, Chapter I §1] that we can extract a subsequence, not relabelled, and functions \( \theta_0 \in C^0([0, T]) \) and \( \phi_0, y_0, p_0 \in C^1([0, T]) \), such that

\[
\begin{align*}
\phi_\varepsilon &\to \phi_0 \quad \text{in} \quad C^1([0, T]), \quad \phi_\varepsilon \overset{*}{\rightharpoonup} \phi_0 \quad \text{in} \quad L^\infty((0, T)), \quad (19a) \\
\theta_\varepsilon &\to \theta_0 \quad \text{in} \quad C([0, T]), \quad \theta_\varepsilon \overset{*}{\rightharpoonup} \theta_0 \quad \text{in} \quad L^\infty((0, T)), \quad (19b) \\
y_\varepsilon &\to y_0 \quad \text{in} \quad C^1([0, T]), \quad \dot{y}_\varepsilon \overset{*}{\rightharpoonup} \dot{y}_0 \quad \text{in} \quad L^\infty((0, T)), \quad (19c) \\
p_\varepsilon &\to p_0 \quad \text{in} \quad C^1([0, T]), \quad p_\varepsilon \overset{*}{\rightharpoonup} p_0 \quad \text{in} \quad L^\infty((0, T)). \quad (19d)
\end{align*}
\]

By taking the limit \( \varepsilon \to 0 \) in equations \( \{16a\}, \{16c\} \) and \( \{16d\} \) and the weak* limit in \( \{16b\} \) we deduce that

\[
\dot{\phi}_0 = \omega(y_0), \quad \dot{\theta}_0 = 0, \quad \dot{y}_0 = p_0, \quad \dot{p}_0 = -\theta_0 \omega'(y_0), \quad (20)
\]

and in particular \( \theta_0 \equiv \theta_\varepsilon \) (compare with \( \{17\} \)). Moreover, since the right-hand side of the limit equation, \( \dot{y}_0 = -\theta_0 \omega'(y_0) \), does not depend on a chosen subsequence, we can discard the extraction of subsequences altogether [6, Principle 5, Chapter I §1].

3.2 Reformulation of the governing equations

For the subsequent part of this work, it is convenient to introduce a notation that simplifies the system of differential equations \( \{16\} \); namely, for \( L_\varepsilon := \log(\omega(y_\varepsilon)) \) and \( k, l \in \mathbb{N}_0 \), we define

\[
D^k D^l y_\varepsilon := \frac{d^k}{dt^k} \frac{\partial^l}{\partial y_\varepsilon^l} L_\varepsilon.
\]

Then \( \{16\} \) reads in the new notation

\[
\begin{align*}
\dot{\phi}_\varepsilon &= \omega(y_\varepsilon) + \frac{\varepsilon}{2} \theta_\varepsilon D_y L_\varepsilon \sin(2\varepsilon^{-1} \phi_\varepsilon) + \frac{\varepsilon^2}{4} \theta_\varepsilon (D_y L_\varepsilon)^2 \sin^2(2\varepsilon^{-1} \phi_\varepsilon), \quad (21a) \\
\dot{\theta}_\varepsilon &= -\theta_\varepsilon p_\varepsilon D_y L_\varepsilon \cos(2\varepsilon^{-1} \phi_\varepsilon) - \frac{\varepsilon}{4} \theta_\varepsilon (D_y L_\varepsilon)^2 \sin(4\varepsilon^{-1} \phi_\varepsilon), \quad (21b) \\
\dot{y}_\varepsilon &= p_\varepsilon + \frac{\varepsilon}{2} \theta_\varepsilon D_y L_\varepsilon \sin(2\varepsilon^{-1} \phi_\varepsilon), \quad (21c) \\
\dot{p}_\varepsilon &= -\theta_\varepsilon \omega'(y_\varepsilon) - \frac{\varepsilon}{2} \theta_\varepsilon p_\varepsilon D_y^2 L_\varepsilon \sin(2\varepsilon^{-1} \phi_\varepsilon) - \frac{\varepsilon^2}{4} \theta_\varepsilon^2 D_y L_\varepsilon D_y^2 L_\varepsilon \sin^2(2\varepsilon^{-1} \phi_\varepsilon). \quad (21d)
\end{align*}
\]
Furthermore, by solving equation (21c) for \( p_\varepsilon \) and insert the resulting expression into (21a), (21b) and (21d), the equations of motion take the final form

\[
\begin{align*}
\dot{\varphi}_\varepsilon &= \omega(y_\varepsilon) + \frac{\varepsilon}{2} D_1 L_\varepsilon \sin \left(2\varepsilon^{-1} \phi_\varepsilon\right), \\
\dot{\theta}_\varepsilon &= -\theta_\varepsilon D_1 L_\varepsilon \cos (2\varepsilon^{-1} \phi_\varepsilon), \\
y_\varepsilon &= p_\varepsilon + \frac{\varepsilon}{2} \theta_\varepsilon D_1 L_\varepsilon \sin (2\varepsilon^{-1} \phi_\varepsilon), \\
\dot{p}_\varepsilon &= -\theta_\varepsilon \omega(y_\varepsilon) - \frac{\varepsilon}{2} \theta_\varepsilon D_1 L_\varepsilon \sin (2\varepsilon^{-1} \phi_\varepsilon).
\end{align*}
\] (22)

3.3 First- and second-order expansion

To analyse the dynamics of the model problem away from the limit \( \varepsilon \to 0 \), a higher-order asymptotic expansion in \( \varepsilon \) is required. As already pointed out in [10], the first-order expansion is only non-zero for \( \theta_\varepsilon \) and hence of limited use. For this reason, we expand \( y_\varepsilon, \theta_\varepsilon \) and \( \phi_\varepsilon \) up to second-order in \( \varepsilon \).

We first define particular functions that appear in the first- and second-order expansion before we state the theorem that embodies the first main result [1].

**Definition 3.1.** Let \((\phi_\varepsilon, \theta_\varepsilon, y_\varepsilon, p_\varepsilon)\) be the solution to (16)–(17) and \((\phi_0, \theta_0, y_0, p_0)\) be as in (15). With the notation introduced in Section 3.2 we define the functions

\[
\begin{align*}
\theta_1^\varepsilon &:= \frac{\theta_\varepsilon - \theta_0}{\varepsilon}, \\
\phi_1^\varepsilon &:= \frac{\phi_\varepsilon - \phi_0}{\varepsilon^2}, \\
y_1^\varepsilon &:= \frac{y_\varepsilon - y_0}{\varepsilon^2}, \\
p_1^\varepsilon &:= \frac{p_\varepsilon - p_0}{\varepsilon^2}, \\
\theta_2^\varepsilon &:= \frac{\theta_\varepsilon - [\theta_1]^\varepsilon}{\varepsilon},
\end{align*}
\] (23)

\[
\begin{align*}
[\theta_1]^\varepsilon &= -\frac{\theta_\varepsilon D_1 L_0}{2\omega(y_0)} \sin(2\varepsilon^{-1} \phi_0), \\
[\phi_1]^\varepsilon &= -\frac{D_1 L_0}{4\omega(y_0)} \cos(2\varepsilon^{-1} \phi_0), \\
[y_1]^\varepsilon &= -\frac{\theta_\varepsilon D_1 L_0}{4\omega(y_0)} \cos(2\varepsilon^{-1} \phi_0), \\
[p_1]^\varepsilon &= \frac{\theta_\varepsilon D_1 L_0}{4\omega(y_0)} \cos(2\varepsilon^{-1} \phi_0)
\end{align*}
\]

and

\[
\begin{align*}
[\theta_2]^\varepsilon &= -\theta_\varepsilon D_1 L_0 [y_2]^\varepsilon - \frac{p_0}{\omega(y_0)} [p_2]^\varepsilon + \frac{\theta_\varepsilon^2 (D_1 L_0)^2}{16\omega(y_0)} \cos(4\varepsilon^{-1} \phi_0) - \frac{\theta_\varepsilon D_1 L_0}{\omega(y_0)} \phi_2 \cos(2\varepsilon^{-1} \phi_0).
\end{align*}
\]

The functions \( \theta_1^\varepsilon, \phi_1^\varepsilon, y_1^\varepsilon \) and \( p_1^\varepsilon \) as defined in (23) describe scaled versions of the residual motion of the originally given degrees of freedom and their homogenised versions. The scaling order is indicated by the corresponding subscript and marks their relevancy in the first- and second-order expansion. To determine the relevant term in the second-order expansion for \( \theta_\varepsilon \), we similarly define by \( \theta_2^\varepsilon \) the scaled residual motion of \( \theta_\varepsilon \) and its first-order expansion, which is derived in a two-step procedure via \( \theta_1^\varepsilon \). As hinted before in [11] the second-order expansions comprise of oscillating and non-oscillating terms. The oscillating terms are denoted by expressions in square brackets, as in the remainder of the definition. The non-oscillatory terms are characterised in the following theorem, which is the main analytic result of this article. One key result is that the non-oscillatory terms of the second-order expansion, marked by an overbar and subscript 2, satisfy a system of ordinary differential equations.

**Theorem 3.2.** The functions specified in Definition 3.1 satisfy

\[
\begin{align*}
\frac{d}{dt} (\theta_1^\varepsilon - [\theta_1]^\varepsilon) &= 0 \quad \text{in} \quad C([0,T]), \\
\frac{d}{dt} (\phi_1^\varepsilon - [\phi_1]^\varepsilon) &= 0 \quad \text{in} \quad C([0,T]), \\
\frac{d}{dt} (y_1^\varepsilon - [y_1]^\varepsilon) &= 0 \quad \text{in} \quad C([0,T]), \\
\frac{d}{dt} (p_1^\varepsilon - [p_1]^\varepsilon) &= 0 \quad \text{in} \quad C([0,T]),
\end{align*}
\]

and

\[
\begin{align*}
\frac{d}{dt} \theta_2^\varepsilon - [\theta_2]^\varepsilon &= 0 \quad \text{in} \quad C([0,T]),
\end{align*}
\] (24)
where \((\tilde{\phi}_2, \tilde{\theta}_2, \bar{y}_2, \bar{p}_2)\) is the unique solution to the inhomogeneous linear system of differential equations

\[
\begin{align*}
\frac{d\bar{y}_2}{dt} &= \omega'(y_0)\bar{y}_2 + \frac{\theta_\ast (D_yL_0)^2}{8} - \frac{(D_tL_0)^2}{8\omega(y_0)}, \\
\frac{d\bar{\theta}_2}{dt} &= \frac{d}{dt} \frac{\theta_\ast (D_tL_0)^2}{8\omega(y_0)}, \\
\frac{d\bar{y}_2}{dt} &= \bar{p}_2 - \frac{\theta_\ast D_yL_0D_yL_0}{4\omega(y_0)}, \\
\frac{d\bar{p}_2}{dt} &= -\omega'(y_0)\bar{\theta}_2 - \frac{\theta_\ast \omega''(y_0)\bar{y}_2}{8} + \frac{\theta_\ast D_yL_0D_yL_0}{4\omega(y_0)},
\end{align*}
\]

with \(\varepsilon\)-independent initial values

\[
\begin{align*}
\bar{\phi}_2(0) &= -[\phi_2]^\varepsilon(0), & \bar{\theta}_2(0) &= -[\theta_2]^\varepsilon(0), & \bar{y}_2(0) &= -[y_2]^\varepsilon(0), & \bar{p}_2(0) &= -[p_2]^\varepsilon(0).
\end{align*}
\]

The results in Theorem 3.2 are central in two different ways. Firstly, it will be crucial for the thermodynamic interpretation we develop in the second part of this article. Secondly, it is interesting for computational purposes. That is, in simulating a natural evolution of a light particle coupled to a heavy particle, their mass ratio \(\varepsilon\) will be small but finite and enters into the underlying model through potentials of different strengths. The result above says that rather than solving the coupled system directly, which is restricted to a small step size to ensure numerical stability, the approximation to second-order can be computed by combining explicitly known oscillatory functions (as given in Definition 3.1) with the solution of a linear inhomogeneous system of differential equations, as given in Theorem 3.2.

The proof of Theorem 3.2 is given in the next section. We remark that we will give a thermodynamic interpretation for the equations \((29a)\) and \((29b)\) governing the evolution of the slow particle, in terms of a constraining second-order energy expression. This formulation is given in \((53)\) in Theorem 3.1 below.

At last, we want to give an alternative formulation of the uniform convergence results in Theorem 3.2 in terms of a nonlinear version of two-scale convergence. Appendix A gives a brief introduction to two-scale convergence, including the definition of two-scale convergence with respect to the nonlinear transformation \(\phi_\ast^{-1} \circ \pi\).

**Corollary 3.3.** With the notation introduced in Appendix A, the uniform convergences in Theorem 3.2 are equivalent to the following strong two-scale convergences with respect to \(\phi_\ast^{-1} \circ \pi\):

\[
\begin{align*}
\phi_\ast \xrightarrow{\phi_\ast^{-1} \circ \pi/2} \phi_2 + [\phi_2] \quad &\text{in} \quad C([0, T] \times S), \\
\bar{y}_2 \xrightarrow{\phi_\ast^{-1} \circ \pi/2} \bar{y}_2 + [y_2] \quad &\text{in} \quad C([0, T] \times S), \\
\bar{\theta}_2 \xrightarrow{\phi_\ast^{-1} \circ \pi/2} \bar{\theta}_2 + [\theta_2] \quad &\text{in} \quad C([0, T] \times S), \\
\bar{p}_2 \xrightarrow{\phi_\ast^{-1} \circ \pi/2} \bar{p}_2 + [p_2] \quad &\text{in} \quad C([0, T] \times S),
\end{align*}
\]

where \((\tilde{\phi}_2, \tilde{\theta}_2, \bar{y}_2, \bar{p}_2)\) is the unique solution to the initial value problem \((29)\) and \((30)\) and where for \(t \in [0, T]\) and \(s \in S\) we define

\[
\begin{align*}
[\theta_1](t,s) &:= -\frac{\theta_\ast D_yL_0(t)}{2\omega(y_0(t))} \sin(2\pi s), & &\text{[\phi_2](t,s) := -} \frac{D_tL_0(t)}{4\omega(y_0(t))} \cos(2\pi s), \\
[y_2](t,s) &:= -\frac{\theta_\ast D_yL_0(t)}{4\omega(y_0(t))} \cos(2\pi s), & &\text{[p_2](t,s) := } \frac{d}{dt} \left( \frac{\theta_\ast D_yL_0(t)}{4\omega(y_0(t))} \right) \cos(2\pi s) \text{.}
\end{align*}
\]

and

\[
\begin{align*}
[\theta_2](t,s) &:= -\frac{\theta_\ast D_yL_0(t)[y_2](t,s) - \frac{p_0(t)}{\omega(y_0(t))}[p_2](t,s) + \frac{\theta_\ast^2(D_yL_0)^2}{16\omega(y_0(t))} \cos(4\pi s) - \frac{\theta_\ast D_tL_0(t)}{\omega(y_0(t))} \phi_2(t) \cos(2\pi s).}
\end{align*}
\]

**Proof.** The equivalence follows from Theorem 3.2 and Proposition 2.4.

### 3.4 Proof of Theorem 3.2

This section comprises lemmas that collectively prove Theorem 3.2. They are stated separately but should be understood in the context of Theorem 3.2 above.

**Lemma 3.4.** There exists \(0 < C < \infty\) and \(0 < \varepsilon_0 < \infty\), where \(\varepsilon_0 = \varepsilon_0(\phi_\ast, \theta_\ast, y_\ast, p_\ast, \omega, C)\), such that \(0 < C \leq \phi_\ast\) for all \(0 < \varepsilon < \varepsilon_0\) small enough.
Proof. The claim follows directly from \([7]\) and \([22a]\).

Remark. Henceforth we assume that \(0 < \varepsilon < \varepsilon_0\) is small enough, so that the conclusion of Lemma \([3,4]\) applies.

Lemma 3.5. Let \(\{u_1\}\) and \(\{\psi_1\}\) be bounded sequences in \(C^{0,1}([0,T])\) and \(C^{1,1}([0,T])\) respectively and \(0 < C \leq \psi_1\). Then, for all \(a, b \in [0,T]\)

\[
\int_a^b u_1 \sin(\varepsilon^{-1} \psi_1) \, dt = O(\varepsilon), \quad \int_a^b u_1 \cos(\varepsilon^{-1} \psi_1) \, dt = O(\varepsilon).
\]

Proof. Integration by parts gives for \(0 < \varepsilon < \varepsilon_0\) small enough

\[
\left| \int_a^b u_1 \exp \left( \frac{i \psi_1}{\varepsilon} \right) \, dt \right| \leq \varepsilon \left| \frac{u_1(a)}{\psi_1(a)} \right| + \varepsilon \left| \frac{u_1(b)}{\psi_1(b)} \right| + \varepsilon \int_a^b \frac{d}{dt} \left( \frac{u_1}{\psi_1} \right) \exp \left( \frac{i \psi_1}{\varepsilon} \right) \, dt = O(\varepsilon).
\]

The claim follows by considering real and imaginary part separately and the isometric isomorphism \([8\) p. 154]

\(C^{k,1,1}([0,T]) \cong W^{k,\infty}((0,T))\).

Lemma 3.6. Let \(u \in C^2(\mathbb{R}_{>0} \times \mathbb{R}^3)\) and \((\phi_1, \theta_1, y_1, p_1)\) be the solution to \([16]\) - \([17]\). Then, the sequence of functions \(\{u_1\}\), where \(u_1 := u(\phi_1, \theta_1, y_1, p_1)\), satisfies for all \(a, b \in [0,T]\)

\[
\int_a^b \dot{u}_1 \cos(2\varepsilon^{-1} \phi_1) \, dt \rightarrow \frac{1}{2} \int_a^b \left[ D_1 L_0 \left( \omega(y_0) \partial_1 u_0 - \theta_1 \partial_2 u_0 + \theta_1 \omega'(y_0) \partial_3 u_0 \right) \right] dt
\]

and

\[
\int_a^b \dot{u}_1 \sin(2\varepsilon^{-1} \phi_1) \, dt = O(\varepsilon).
\]

Proof. The equations in \([22]\) imply after some calculations that

\[
\dot{u}_1 = \partial_1 u_1 \left( \dot{u}_1 \omega(y_1) + \frac{D_1^2 L_0}{2} \sin(2\varepsilon^{-1} \phi_1) + D_1 L_0 \dot{\phi}_1 \cos(2\varepsilon^{-1} \phi_1) \right) - \partial_2 u_1 \theta_1 L_0 \cos(2\varepsilon^{-1} \phi_1)
\]

\[
- \partial_3 u_1 \left( \theta_1 \omega'(y_1) - \theta_1 \omega'(y_1) \cos(2\varepsilon^{-1} \phi_1) \right) + \theta_1 u_1 \dot{y}_1.
\]

The claim follows from the uniform convergence results in \([19]\), Lemma \([3,5]\) and the trigonometric identities

\[
2 \cos(x) \cos(y) = \cos(x + y) + \cos(x - y), \quad 2 \cos(x) \sin(y) = \sin(x + y) - \sin(x - y).
\]

Lemma 3.7. The sequences \(\{\theta_1^1\}, \{\phi_1^2\}, \{y_1^2\}\) and \(\{p_1^2\}\) are uniformly bounded in \(L^\infty((0,T))\).

Proof. In the following proof, the constant \(0 \leq C < \infty\) is dependent on \(T\) but independent of \(\varepsilon\) and can take on different values from line to line. Let \(t \in [0,T]\) and \(0 < \varepsilon < \varepsilon_0\) small enough and let

\[
M_1 := \sup_{0 < \varepsilon < \varepsilon_0} \sup_{h \in [0,1]} \| \omega'(1 - h y_1 + h y_0) \|_{L^\infty((0,T))}, \quad M_2 := \sup_{0 < \varepsilon < \varepsilon_0} \sup_{h \in [0,1]} \| \omega''(1 - h y_1 + h y_0) \|_{L^\infty((0,T))}.
\]

We apply Lemma \([3,5]\) to equation \([22a]\),

\[
|\phi_1^2(t)| = \int_0^t \dot{\phi}_1^2 \, ds \leq \frac{1}{\varepsilon^2} \int_0^t \omega(y_1) - \omega(y_0) \, ds + \frac{1}{2\varepsilon} \int_0^t D_s L_0 \sin(2\varepsilon^{-1} \phi_1) \, ds \leq M_1 \int_0^t |\dot{y}_1^2| \, ds + C, \quad (31)
\]

then to equation \([22b]\),

\[
|\theta_1(t)| = \int_0^t \dot{\theta}_1 \, ds = \frac{1}{\varepsilon} \int_0^t \theta_1 D_s L_0 \cos(2\varepsilon^{-1} \phi_1) \, ds \leq C, \quad (32)
\]

to equation \([22c]\),

\[
|y_1^2(t)| = \int_0^t \dot{y}_1^2 \, ds \leq \int_0^t |p_1^2| \, ds + \frac{1}{2\varepsilon} \int_0^t \theta_1 D_s L_0 \sin(2\varepsilon^{-1} \phi_1) \, ds \leq \int_0^t |p_1^2| \, ds + C, \quad (33)
\]
Therefore, writing $\varepsilon$ and expanding the energy function (15) up to second-order in $\phi$ scale dynamics. In the following, Lemma 3.9, 3.10 and 3.11 provide information about the decomposition of the $\varepsilon$ for $\theta$. Finally, a variation of the classical Grönwall inequality (see [14, p. 383]) implies that

$$B_\varepsilon$$

By combining the inequalities (33)–(35) we obtain

$$|y_\varepsilon^2(t)| \leq C + \theta_* M_2 \int_0^T \int_0^T |y_\varepsilon^2| \, dr \, ds.$$ 

Finally, a variation of the classical Grönwall inequality (see [14, p. 383]) implies that

$$|y_\varepsilon^2(t)| \leq C \exp \left( \theta_* M_2 T^2 \right),$$

for $t \in [0, T]$, which together with (33)–(35) yields the uniform bound for $\{\theta_\varepsilon^1\}, \{\phi_\varepsilon\}, \{y_\varepsilon^2\}$ and $\{p_\varepsilon^2\}$. 

**Lemma 3.8.** The sequence $\{\theta_\varepsilon^1\}$ is uniformly bounded in $L^\infty((0, T))$.

**Proof.** According to Lemma 3.7 the sequences $\{\theta_\varepsilon^1\}, \{\phi_\varepsilon\}, \{y_\varepsilon^2\}$ and $\{p_\varepsilon^2\}$ are uniformly bounded in $L^\infty((0, T))$. Therefore, writing

$$\theta_\varepsilon = \theta_* + \varepsilon \theta_\varepsilon^1, \quad \phi_\varepsilon = \phi_0 + \varepsilon^2 \phi_\varepsilon^2, \quad y_\varepsilon = y_0 + \varepsilon^2 y_\varepsilon^2, \quad p_\varepsilon = p_0 + \varepsilon^2 p_\varepsilon^2$$

and expanding the energy function (15) up to second-order in $\varepsilon$ gives $E_\varepsilon = E_0 + \varepsilon E_\varepsilon^1 + O(\varepsilon^2)$ with

$$E_0 := \frac{1}{2} p_0^2 + \theta_* \omega(y_0), \quad E_\varepsilon^1 := \omega(y_0) \theta_\varepsilon^1 + \frac{\theta_* D_y L_0}{2} \sin(2\varepsilon^{-1} \phi_0),$$

for $0 < \varepsilon < \varepsilon_0$ small enough. According to (20), the energy $E_0$ is constant. It follows from (11) that $E_\varepsilon = E_0 = E_*$ and thus $E_\varepsilon^1 = O(\varepsilon)$. This yields the claim as

$$\theta_\varepsilon^1 - [\theta_\varepsilon] = O(\varepsilon).$$

Due to the oscillatory character of the problem, Lemma 3.8 shows that the first-order asymptotic expansion in $\theta_\varepsilon$ is expressed by a high-frequency term which represents small-scale oscillations of order $\varepsilon$. Averaging over these oscillations, that is, taking the weak* limit shows that on average $\theta_\varepsilon^1$ has zero effect on the first-order macro-scale dynamics. In the following, Lemma 3.9, 3.10 and 3.11 provide information about the decomposition of the second-order asymptotic expansion of $\phi_\varepsilon, \theta_\varepsilon, y_\varepsilon$ and $p_\varepsilon$ into high-frequency terms with zero average contribution and terms with non-zero average contribution, specifying the macro-scale dynamics to second-order.

**Lemma 3.9.** Let $u_0, \psi_0 \in C^1([0, T])$ and let $\{u_\varepsilon\}, \{\psi_\varepsilon\}$ be sequences in $C^1([0, T])$ such that the sequences $\{u_\varepsilon\}, \{\varepsilon^{-1} (u_\varepsilon - u_0)\}, \{\varepsilon^{-2} (\psi_\varepsilon - \psi_0)\}$ and $\{\varepsilon^{-1} (\psi_\varepsilon - \psi_0)\}$ are bounded in $L^\infty((0, T))$. Then for $v_\varepsilon$ such that

$$v_\varepsilon := u_\varepsilon \cos(\varepsilon^{-1} \psi_\varepsilon) - u_0 \cos(\varepsilon^{-1} \psi_0),$$

the sequence $\{\varepsilon^{-1} v_\varepsilon\}$ is bounded in $L^\infty((0, T))$ and in particular

$$v_\varepsilon \to 0 \quad \text{in} \quad C([0, T]), \quad \dot{v}_\varepsilon \overset{\varepsilon}{\to} 0 \quad \text{in} \quad L^\infty((0, T)).$$

11
Proof. By writing
\[ w_\varepsilon := (u_\varepsilon - u_0) \exp(i\varepsilon^{-1} \psi_\varepsilon) - u_0 \exp(i\varepsilon^{-1} \psi_0)(1 - \exp(i\varepsilon^{-1} (\psi_\varepsilon - \psi_0))) \]
and
\[ \dot{w}_\varepsilon = \left( (\dot{u}_\varepsilon - \dot{u}_0) + i\varepsilon^{-1} \psi_\varepsilon (u_\varepsilon - u_0) + i\varepsilon^{-1} u_0 (\dot{\psi}_\varepsilon - \dot{\psi}_0) \right) \exp(i\varepsilon^{-1} \psi_\varepsilon) \]
- \left( \dot{u}_0 + i\varepsilon^{-1} u_0 \dot{\psi}_0 \right) (1 - \exp(i\varepsilon^{-1} (\psi_\varepsilon - \psi_0))) \exp(i\varepsilon^{-1} \psi_0),

the assumptions imply that the sequences \( \{\varepsilon^{-1} w_\varepsilon\} \) and \( \{\dot{w}_\varepsilon\} \) are bounded in \( L^\infty ((0, T), \mathbb{C}) \), which yields directly the uniform convergence of \( w_\varepsilon = \Re(w_\varepsilon) \) to zero. The weak* convergence of \( \dot{w}_\varepsilon = \Re(\dot{w}_\varepsilon) \) follows from [6, Principle 1, Chapter I §1]. \( \square \)

Remark. Lemma 3.8 and Lemma 3.9 imply the convergence (24).

Lemma 3.10. There exists a subsequence \( \{\varepsilon'\} \) and functions \( \phi_2, \bar{y}_2, \bar{p}_2 \in C^{0,1}([0, T]) \) such that the convergences (25)–(27) hold.

Proof. By taking the time derivative of the functions \( \phi_2^\varepsilon - [\phi_2]^\varepsilon, y_2^\varepsilon - [y_2]^\varepsilon \) and \( p_2^\varepsilon - [p_2]^\varepsilon \), we obtain
\[ \frac{d}{dt} (\phi_2^\varepsilon - [\phi_2]^\varepsilon) = \frac{\omega(y_\varepsilon) - \omega(y_0)}{\varepsilon^2} + \frac{d}{dt} \left( \frac{D_L L_0}{4\phi_\varepsilon} \right) \cos(2\varepsilon^{-1} \phi_\varepsilon) - \frac{d}{dt} \left( \frac{[\phi_2]^\varepsilon + D_L L_0}{4\phi_\varepsilon} \cos(2\varepsilon^{-1} \phi_\varepsilon) \right), \tag{36} \]
\[ \frac{d}{dt} (y_2^\varepsilon - [y_2]^\varepsilon) = \frac{p_\varepsilon - p_0}{\varepsilon^2} + \frac{d}{dt} \left( \frac{\theta_L D_L L_0}{4\phi_\varepsilon} \right) \cos(2\varepsilon^{-1} \phi_\varepsilon) - \frac{d}{dt} \left( y_2^\varepsilon + \frac{\theta_L D_L L_0}{4\phi_\varepsilon} \cos(2\varepsilon^{-1} \phi_\varepsilon) \right), \tag{37} \]
\[ \frac{d}{dt} (p_2^\varepsilon - [p_2]^\varepsilon) = -\dot{\theta}_e \omega' (y_\varepsilon) - \omega' (y_0) + \frac{\theta_1}{\varepsilon} \omega' (y_\varepsilon) \]
- \frac{d}{dt} \left( \frac{\theta_L D_L L_0}{4\phi_\varepsilon} \right) \cos(2\varepsilon^{-1} \phi_\varepsilon) - \frac{d}{dt} \left( \frac{[p_2]^\varepsilon - \theta_L D_L L_0}{4\phi_\varepsilon} \cos(2\varepsilon^{-1} \phi_\varepsilon) \right) \tag{38} \]
where we write \( [p_2]^\varepsilon = \frac{\theta_L D_L L_0}{4\omega(y_0)} \cos(2\varepsilon^{-1} \phi_0) \), \( [p_2]^\varepsilon = -\frac{\theta_L D_L L_0}{4\omega(y_0)} \cos(2\varepsilon^{-1} \phi_0) \).

For the derivation of equation (38), we note that in
\[ \frac{dp_2^\varepsilon}{dt} = -\dot{\theta}_s \omega'(y_\varepsilon) - \omega'(y_0) - \frac{\theta_2 - \theta_s}{\varepsilon^2} \omega'(y_\varepsilon) - \frac{d}{dt} \left( \frac{\theta_L D_L L_0}{4\omega(y_0)} \right) \omega'(y_\varepsilon) \cos(2\varepsilon^{-1} \phi_\varepsilon) + \frac{d}{dt} \left( \frac{\theta_L D_L L_0}{4\omega(y_0)} \omega'(y_\varepsilon) \cos(2\varepsilon^{-1} \phi_\varepsilon) \right), \]
we can rewrite the second term on the right hand side by introducing \( [\theta_1]^\varepsilon \), i.e.,
\[ \frac{\theta_2 - \theta_s}{\varepsilon^2} \omega'(y_\varepsilon) = \frac{\theta_1}{\varepsilon} \frac{\theta_1}{\varepsilon} \omega'(y_\varepsilon) - \frac{d}{dt} \left( \frac{\theta_L D_L L_0}{4\omega(y_0)} \omega'(y_\varepsilon) \right) \cos(2\varepsilon^{-1} \phi_\varepsilon) + \frac{d}{dt} \left( \frac{\theta_L D_L L_0}{4\omega(y_0)} \omega'(y_\varepsilon) \cos(2\varepsilon^{-1} \phi_\varepsilon) \right). \]

By Lemma 3.7, 3.8 and 3.9, the sequences \( \{\phi_2^\varepsilon - [\phi_2]^\varepsilon\}, \{y_2^\varepsilon - [y_2]^\varepsilon\} \) and \( \{p_2^\varepsilon - [p_2]^\varepsilon\} \) are bounded in the space \( C^{0,1}([0, T]) \) of uniformly Lipschitz continuous functions. The claim follows after successive applications of [6, Principle 4, Chapter I §1]. \( \square \)

Lemma 3.11. Under the subsequence extracted in Lemma 3.10, we obtain the convergence (28), where \( \bar{\theta}_2 \) is of the form
\[ \bar{\theta}_2 = -\frac{p_0}{\omega(y_0)} p_2 - \theta_s D_L L_0 \bar{y}_2 - \frac{\theta_2^2 (D_L L_0)^2}{16\omega(y_0)} + \frac{\theta_s (D_L L_0)^2}{4\omega^3(y_0)}. \tag{39} \]

Proof. By Lemma 3.10 we can write
\[ \phi_\varepsilon = \phi_0 + \varepsilon^2 (\phi_2^\varepsilon + [\phi_2]^\varepsilon) + \varepsilon^2 \phi_4, \]
\[ \theta_\varepsilon = \theta_s + \varepsilon [\theta_1]^\varepsilon + \varepsilon^2 \theta_2, \]
\[ y_\varepsilon = y_0 + \varepsilon^2 (\bar{y}_2 + [y_2]^\varepsilon) + \varepsilon^2 \bar{y}_4, \]
\[ p_\varepsilon = p_0 + \varepsilon^2 (\bar{p}_2 + [p_2]^\varepsilon) + \varepsilon^2 \bar{p}_4, \]
\[ v_\varepsilon = v_0 + \varepsilon^2 (\bar{v}_2 + [v_2]^\varepsilon) + \varepsilon^2 \bar{v}_4. \]
where \( \phi_3^\varepsilon, y_3^\varepsilon, p_3^\varepsilon \to 0 \) in \( C([0,T]) \). An expansion of the energy function \( \text{(15)} \) up to second-order in \( \varepsilon \) gives
\[
E_\varepsilon = E_0 + \varepsilon E_1^\varepsilon + \varepsilon^2 E_2^\varepsilon + \varepsilon^2 E_3^\varepsilon,
\]
where \( E_3^\varepsilon \to 0 \) in \( C([0,T]) \) and
\[
E_0 := \frac{1}{2} p_0^2 + \theta_1 \omega_0(y_0),
E_1^\varepsilon := \omega(y_0)\theta_1 \varepsilon + \theta_2 \varepsilon p_0 \omega'(y_0) \sin(2\varepsilon^{-1}\phi_0),
E_2^\varepsilon := p_0 (p_2 + [p_2^\varepsilon]) + \theta_1 \omega(y_0) (y_2 + [y_2^\varepsilon]) + \omega(y_0) \theta_2 \varepsilon + \frac{\theta_2^2 (D_y L_0)^2}{8} \sin^2(2\varepsilon^{-1}\phi_0)
\]
\[+ \theta_1 D_1 L_0 \left( \dot{\phi}_2 + [\phi_2^\varepsilon] \right) \cos(2\varepsilon^{-1}\phi_0) + \frac{[\theta_1 \varepsilon D_1 L_0]}{2} \sin(2\varepsilon^{-1}\phi_0) = \omega(y_0) \left( \theta_2^\varepsilon - [\theta_2^\varepsilon] \right).\]

It follows from \( \text{(9)} \) that \( E_\varepsilon = E_0 = E_* \) and by Lemma \( \text{(38)} \) that \( E_2^\varepsilon = 0 \). This implies that \( E_3^\varepsilon + E_3^\varepsilon = 0 \) and hence \( E_\varepsilon = -E_3^\varepsilon \to 0 \) in \( C([0,T]) \). The claim follows with the identity
\[
\theta_1 D_1 L_0 \left( \dot{\phi}_2 + [\phi_2^\varepsilon] \right) \cos(2\varepsilon^{-1}\phi_0) + \frac{[\theta_1 \varepsilon D_1 L_0]}{2} \sin(2\varepsilon^{-1}\phi_0) = -\frac{\theta_1 (D_1 L_0)^2}{4\omega(y_0)}.\]

**Lemma 3.12.** The extraction of a subsequence in Lemma \( \text{(7,17)} \) can be discarded altogether and \( (\dot{\phi}_2, \dot{\theta}_2, \dot{y}_2, \dot{p}_2) \) is the unique solution to the initial value problem \( \text{(29)}, \text{(31)} \).

**Proof.** The differential equations \( \text{(29a)}, \text{(29c)} \) and \( \text{(29d)} \) follow from \( \text{(26)}, \text{(27)} \) by taking the weak* limit in combination with Lemma \( \text{(3.3)} \) and Lemma \( \text{(3.9)} \) and \( \text{[6] Lemma 1, Chapter I §1} \). To prove formula \( \text{(29b)} \), we differentiate equation \( \text{(39)} \) with respect to time and use equation \( \text{(29c)} \) and \( \text{(29d)} \) together with
\[
D_2^\varepsilon L_0 = -\theta_1 \omega(y_0) D_y L_0 + \gamma_2 \varepsilon D_2^\varepsilon L_0.
\]
The initial values \( \text{(31)} \) can be derived from the uniform convergence in \( \text{(26)}, \text{(28)} \). Furthermore, since the right-hand side of \( \text{(29)} \) and therefore the solution \( (\dot{\phi}_2, \dot{\theta}_2, \dot{y}_2, \dot{p}_2) \in C^\infty([0,T], \mathbb{R}^4) \) — does not depend on the chosen subsequence, \( \text{[6] Principle 5, Chapter I §1} \) allows us to discard the extraction of subsequences altogether.

## 4 Thermodynamic expansion and interpretation

We now give a thermodynamic interpretation of the analytic result presented in Theorem \( \text{3.2} \). Thermodynamic effects can in principle occur when a separation of scales exist; Hertz \( \text{[10]} \) developed a thermodynamic theory for Hamiltonian systems with slowly varying external parameter \( \text{[10]} \). The model considered in this article is an example of this kind if we restrict the analysis to the fast particle (variable \( z_* \)) and consider the slow particle (variable \( y_* \)) as an external parameter. The question we want to address in this section is “Can we replace the dynamics of the fast particle by a thermodynamic description in terms of temperature and entropy?” An answer to this question could potentially lead to new algorithms that reduce the computational complexity of large-scale molecular dynamics simulations either by allowing for a larger step size or a reduction of the system’s dimensions. Although a larger step size can be used to integrate the system of differential equations \( \text{(29)} \), which decreases the computational complexity, a reduction in the dimension of the model problem is not expected because a new algorithm would only involve a substitution of two degrees of freedom, i.e., the generalised position and momentum of one particle, by two thermodynamic state variables. Nonetheless, we study this problem to develop a first thermodynamic understanding. As it turns out, even in this simple model problem, an interesting adiabatic/non-adiabatic characteristic emerges through a higher-order asymptotic expansion.

For a thermodynamic interpretation of the system, we will regard the fast particle \( z_* \) as a heat bath acting on the slow particle \( y_* \). As such, we will mainly focus our thermodynamic analysis on the energy associated with the fast particle, which we call in the following the heat bath energy \( E_\varepsilon^\perp \), in contrast to the residual energy, which we call the environmental energy \( E_\varepsilon^\parallel \). Both energies can be read off from the total energy \( \text{(9)} \), i.e.,
\[
E_\varepsilon^\perp = \frac{1}{2} z_*^2 + \varepsilon z_*^2 \omega^2(y_*) z_*^2, \quad E_\varepsilon^\parallel = E_\varepsilon - E_\varepsilon^\perp.
\]

Note that the evolution of the fast degree of freedom \( z_* \) is governed by the energy \( E_\varepsilon^\perp = E_\varepsilon^\perp (z_*, \dot{z}_*; y_*) \), which is subject to a dynamically varying external parameter given by the evolution of the slow degree of freedom \( y_* \). This framework allows us to apply the theory developed by Hertz \( \text{[5]} \). From a lengthy analysis, which we describe in the Appendix \( \text{[3]} \), we derive for \( \varepsilon > 0 \) the following expressions for the temperature \( T_\varepsilon \), the entropy \( S_\varepsilon \) and the external force \( F_\varepsilon \) in the fast subsystem:
\[
T_\varepsilon = \theta_\varepsilon \omega'(y_\varepsilon), \quad S_\varepsilon = \log(\theta_\varepsilon) + C, \quad F_\varepsilon = \theta_\varepsilon \omega'(y_\varepsilon).
\]
In combination with the second-order expansion derived in Theorem 3.2, we will analyse the asymptotic properties of the thermodynamic expressions above, by expanding \(T_\varepsilon = T_0 + \mathcal{O}(\varepsilon), \ F_\varepsilon = F_0 + \mathcal{O}(\varepsilon)\) and \(S_\varepsilon = S_0 + \varepsilon[S_1]^\varepsilon + \varepsilon^2[S_2]^\varepsilon + \varepsilon^2 S_3^\varepsilon\) with \(S_3^\varepsilon \rightarrow 0\) in \(C([0,T])\), where
\[
T_0 := \theta_\ast \omega(y_0), \quad F_0 := \theta_\ast \omega'(y_0)
\] (42)
and
\[
S_0 := \log(\theta_\ast) + C, \quad [S_1]^\varepsilon := \left[\frac{[\theta_1]^\varepsilon}{\theta_\ast}\right], \quad [S_2]^\varepsilon := \frac{\bar{\theta}_2 + [\theta_2]^\varepsilon}{\theta_\ast} - \frac{1}{2} \left(\frac{[\theta_1]^\varepsilon}{\theta_\ast}\right)^2.
\] (43)

Analogously, we expand the energy of the fast subsystem \(E_\varepsilon^+ = \theta_\varepsilon \omega(y_\varepsilon) = E_0^+ + \varepsilon[E_1^+] + \varepsilon^2[E_2^+] + \varepsilon^2 E_3^+\) where \(E_3^+ \rightarrow 0\) in \(C([0,T])\) and
\[
E_0^+ := \theta_\ast \omega(y_0), \quad [E_1^+] := \omega(y_0) [\theta_1]^\varepsilon, \quad [E_2^+] := \omega'(y_0) (\bar{y}_2 + [y_2]^\varepsilon) + \omega(y_0) (\bar{\theta}_2 + [\theta_2]^\varepsilon).
\] (44)

\[4.1 \quad \text{Leading-order thermodynamics: constant entropy}\]

We show in this section, following Bornemann [8], that to leading-order (limit \(\varepsilon \rightarrow 0\)), the resulting thermodynamic process is adiabatic or in other words a thermodynamic process with constant entropy.

\[4.1.1 \quad \text{Thermodynamics of the limit process}\]

As an aside, we briefly sketch how the thermodynamic nature of the problem considered in this article materialises in the thermodynamic principles that underpin the proof of Theorem 1.1. This observation is independent of the conclusions we will draw about the adiabatic nature of the limit process.

Firstly, the proof in [8] uses the equi-partitioning of the heat bath energy \(E_\varepsilon^+\) in the weak* limit. To illustrate this, we consider the quantity \(\Xi_\varepsilon := \bar{z}_e z_e\), which is of order \(\varepsilon\) and hence converges uniformly to zero. Its time derivative is given by
\[
\dot{\Xi}_\varepsilon = \bar{z}_e \dot{z}_e + \bar{z}_e^2 = -\varepsilon^2 \omega^2(y_\varepsilon) z_e^2 + \bar{z}_e^2 = -2U_\varepsilon + 2K_\varepsilon^+,
\] (45)
where \(U_\varepsilon^+\) is the potential and \(K_\varepsilon^+\) kinetic energy of the fast degree of freedom. It follows from [11] Principle 1, Chapter I §1 that \(\Xi_\varepsilon\) converges weakly* to \(0 = -U_0^+ + K_0^+\), which implies the equi-partitioning of the energy \(E_0^+\) into kinetic and potential energy, i.e., \(U_\varepsilon^+ = \frac{1}{2} E_\varepsilon^+\) and \(K_\varepsilon^+ = \frac{1}{2} E_\varepsilon^+\).

Secondly, the proof in [8] utilises the adiabatic invariance of the action \(\theta_\ast \rightarrow \theta_\ast\) in the limit \(\varepsilon \rightarrow 0\), see (19). The action, which was used in the transformation into action-angle variables [14], takes the form of the energy-frequency ratio \(\theta_\varepsilon = E_\varepsilon^+/\omega(y_\varepsilon)\). Since the time evolution of the energy \(E_\varepsilon^+\) and the external variable \(y_\varepsilon\) are in general independent, the adiabatic invariance of the action reveals their dependence in the limit \(\varepsilon \rightarrow 0\), as \(\theta_\ast = E_\varepsilon^+/\omega(y_0)\).

\[4.1.2 \quad \text{Leading-order thermodynamics: Adiabatic invariance}\]

The concept of adiabatic invariance finds applications in the analysis of slowly perturbed dynamical systems, where one is primarily interested in the derivation of the effective evolution of the system. It emerged in celestial mechanics in form of the perturbation theory of Hamiltonian dynamical systems [2] Chapter 10, and can be found in many other fields. In particular, adiabatic invariance plays a key role in thermodynamics. There, adiabatic processes are idealised models in the limit of an infinite separation of time-scales and are, by definition, processes with constant entropy. Thus, for adiabatic processes the entropy reveals, similar to above, a dependence of the internal energy \(E\) and the external parameter \(y\), as \(S(E,y) = \text{const}\). An introduction to the thermodynamic theory as developed by Hertz can be found in Appendix [13].

Let us now have a closer look at \(\theta_\ast = \text{const}\). Naturally, every function of \(\theta_\ast = E_0^+/\omega(y_0)\) is a constant of motion. On the other hand, every differentiable invariant of motion must be a function of \(\theta_\ast\). This follows from a contradiction argument [5] Chapter 1.5, which we sketch for the reader’s convenience. Assume that there is another invariant \(S(E_\varepsilon^+, y_\varepsilon)\) with \(\dot{S} = 0\). Then with \(E_\varepsilon^+ = E_\varepsilon^+(\theta_\ast, y_0)\) we can write, with slight abuse of the notation, \(S(E_\varepsilon^+(\theta_\ast, y_0), y_0) = S(\theta_\ast, y_0)\). Taking the time derivative we get
\[
0 = \frac{dS}{dt} = \frac{\partial S}{\partial \theta_\ast} \dot{\theta}_\ast + \frac{\partial S}{\partial y_0} \dot{y}_0 = \frac{\partial S}{\partial y_0} \dot{y}_0.
\]
Since in general \(\dot{y}_0 \neq 0\), it follows that \(\partial S/\partial \theta_\ast = 0\) and hence \(S = S(\theta_\ast)\). Therefore, since the entropy is a constant of motion for an adiabatic thermodynamic process, we can conclude that in the limit \(\varepsilon \rightarrow 0\) the entropy is a function of \(\theta_\ast\), i.e., \(S = S(\theta_\ast)\).

In fact, by comparing this result with the leading-order expansion of the temperature, entropy and external force in the model problem as derived in (42) and (43), i.e.
\[
T_0 = \theta_\ast \omega(y_0), \quad S_0 = \log(\theta_\ast) + C, \quad F_0 = \theta_\ast \omega'(y_0),
\] (46)
we observe, that \( S_0 = S_0(\theta_*) = \text{const.} \) and hence reason that the limit process is adiabatic. This is in particular a result of the external parameter \( y_0 \), which affects the fast system to leading-order only slowly. The energy in the limit \( \varepsilon \to 0 \) (see equation (41)) is given by \( E_0^\perp(y_0) = \theta_\ast \omega(y_0) \), and therefore (cf. equation (57))

\[
dE_0^\perp = F_0 dy_0 + T_0 dS_0 = F_0 dy_0,
\]

which coincides with the qualitative intuition presented in Section 5.1. Note that by action and reaction, the force exerted on the fast subsystem \( F_0 \) is equal but of opposite sign to the force acting on the environment \( -F_0 \) (see also (20)).

4.2 Second-order thermodynamics

4.2.1 Rescaling of the process

Recall that our main goal is the derivation of a higher-order effective evolution of the slow degree of freedom \( y_\varepsilon \). With a thermodynamic description, we aim to supplement the most dominant motion of \( y_\varepsilon \), i.e. \( y_0 \), by an effective description of the interacting fast particle \( z_\varepsilon \), which can be thought of as a heat bath acting on \( y_\varepsilon \). For the slow degree of freedom, the typical time-scale is of order \( \mathcal{O}(1) \), whereas for the fast degree of freedom \( z_\varepsilon \) it is of order \( \mathcal{O}(1/\varepsilon) \). We remark that for the thermodynamic analysis, it is important to shift the viewpoint — while the overarching aim is to derive thermodynamic corrections to the slow sub-system, from a thermodynamic point of view the analysis itself has to focus on the fast system with its exposure to the slow external agent.

To derive this dualistic viewpoint, we introduce a scaling of \( z_\varepsilon \) in space and time such that its typical time- and length-scale is of order \( \mathcal{O}(1) \) and consequently \( y_\varepsilon = \mathcal{O}(\varepsilon) \). We show in Appendix B that the dynamics of \( z_\varepsilon \) is then described by a prototypical thermodynamic model, namely a slowly perturbed harmonic oscillator, which is in the limit of an infinite separation of time-scale in thermal equilibrium. Here, in the limit \( \varepsilon \to 0 \), the change of the external agent \( y_0 \) is regarded as infinitely small and the constant value \( \theta_* \) is geometrically given as the phase space volume enclosed by the energy surface for a fixed value of \( y_0 \) (see [5] or [10]). In this context, a thermodynamic process can be defined as a sequence of thermodynamic equilibrium states in which \( y_0 \) is static for every instance in time but dynamically changing in the course of the sequence. Such processes are called quasi-static adiabatic processes in classical thermodynamics [23, Chapter 1.4]. These processes are characterised by a constant entropy. In contrast, processes with non-constant entropy involve a fast change of the external parameter, as noted in [5, Chapter 1.2].

4.2.2 Higher-order thermodynamic properties

Using this scaling of space and time of \( z_\varepsilon \) as worked out in Appendix B, we are able to derive the temperature \( T_0 \) and external force \( F_0 \) based on the time average of certain quantities for fixed energy \( E_0^\perp \) and external parameter \( y_0 \). To analyse the thermodynamic properties for dynamically changing \( E_0^\perp \) and \( y_0 \), we will focus on the original scaling as in (40) and regard the evolution as a quasi-static thermodynamic process. Inspired by the equipartitioning of the energy \( E_0^\perp \) (see (15)), we take the weak* limit as the corresponding averaging operator in the original scaling to derive thermodynamic quantities.

Therefore, we calculate the average contribution of the higher-order micro-scale oscillations in \( E_2^\perp \) and \( S_2 \) by taking the weak* limit of the asymptotic expansion terms \( [E_1^0]^\perp, [E_2^0]^\perp, [S_1]^\perp \) and \( [S_2]^\perp \). This yields

\[
\begin{align*}
[E_1^0]^\perp \xrightarrow{\ast} & 0 \quad \text{in} \quad L^\infty((0,T)), \\
[E_2^0]^\perp \xrightarrow{\ast} & E_2^\perp := \theta_* \omega(y_0) \bar{y}_2 + \omega(y_0) \bar{\theta}_2 \quad \text{in} \quad L^\infty((0,T)), \\
[S_1]^\perp \xrightarrow{\ast} & 0 \quad \text{in} \quad L^\infty((0,T)), \\
[S_2]^\perp \xrightarrow{\ast} & S_2 := \frac{\theta_2}{\theta_*} - \left( \frac{D_t L_0}{4\omega(y_0)} \right)^2 \quad \text{in} \quad L^\infty((0,T)).
\end{align*}
\]

We can now define the second-order average heat bath energy and entropy as

\[
E_2^\perp := E_0^\perp + \varepsilon^2 E_2^\perp, \quad S_\varepsilon := S_0 + \varepsilon^2 \bar{S}_2,
\]

where \( \bar{S}_2 := \bar{\theta}_2/\theta_* \). Note that we do not include the second term of the weak* limit of \( [S_2]^\ast \) in (49) in the definition of \( \bar{S}_2 \), since this term does not appear in the energy expansion. It describes the effects of the first-order fast dynamics on the second-order dynamics, which does not affect the average second-order energy correction \( E_2^\perp \).

To analyse the thermodynamic properties of \( E_2^\perp \) for \( \varepsilon > 0 \), we focus now on the second-order expansion term \( E_2^\perp \). The appropriate temperature, entropy and external force can be read off from (48) and (49),

\[
T_0 = \theta_* \omega(y_0), \quad \bar{S}_2 = \bar{\theta}_2/\theta_* , \quad F_0 = \theta_* \omega(y_0).
\]

Note that the entropy in this case is not constant. This can be explained by the second-order correction of the external parameter \( y_\varepsilon \), which exhibits according to Theorem 4.2 a decomposition into a slowly varying component
\( \bar{y}_2 \) and a rapidly varying component \([y_2]^\epsilon\). By considering \( E_2^+ = E_2^+(\bar{S}_2, \bar{y}_2) \) we obtain (cf. equation (55))
\[
d\bar{E}_2^+ = F_0 d\bar{y}_2 + T_0 d\bar{S}_2,
\]
which agrees with the qualitative discussion of Section B.1 below.

Finally, let us inspect how the thermodynamic energy balance is realised in the total second-order energy correction of \( E_\epsilon \). Analogous to the decomposition above, we split the total energy \( E_\epsilon \) into the heat bath energy \( E_\epsilon^+ \) and the environmental energy \( E_\epsilon^- \), i.e., \( E_\epsilon = E_\epsilon^+ + E_\epsilon^- \), where
\[
E_\epsilon^\parallel = \frac{1}{2} \frac{\varepsilon^2}{\theta_\epsilon^} \int \rho_\epsilon^2 \theta_\epsilon^ D_\lambda L_\epsilon \sin(2\varepsilon^{-1} \phi_\epsilon) + \frac{\varepsilon^2}{8} \theta_\epsilon^2 (D_\lambda L_\epsilon)^2 \sin^2(2\varepsilon^{-1} \phi_\epsilon).
\]

We then use the expressions derived in Theorem 3.2 to expand \( E_\epsilon \) into \( E_\epsilon^0 + \varepsilon [E_1^+] + \varepsilon^2 [E_2^+] + \varepsilon^2 E_3^\parallel \), where \( E_3^\parallel \rightarrow 0 \) in \( C([0, T]) \) with
\[
E_\epsilon^0 := \frac{1}{2} \rho_0^2 \quad \text{and} \quad [E_1^+] := \frac{1}{2} \theta_\epsilon^ D_\lambda L_0 \sin(2\varepsilon^{-1} \phi_\epsilon)
\]
and
\[
[E_2^+] := p_0 (p_2^+ + [p_2^+]) + \frac{\theta_\epsilon^2 (D_\lambda L_0)^2}{8} \sin^2(2\varepsilon^{-1} \phi_\epsilon) + \theta_\epsilon^ D_\lambda L_0 (\bar{\phi}_2 + [\phi_2^+]) \cos(2\varepsilon^{-1} \phi_\epsilon) + \frac{[\theta_\epsilon^]}{2} \theta_\epsilon^ D_\lambda L_0 \sin(2\varepsilon^{-1} \phi_\epsilon).
\]
As before, we take the weak* limit to determine the average energy correction at first- and second-order, and find
\[
[E_1^+]^\ast \rightarrow 0 \quad \text{in} \quad L^\infty((0, T)), \quad [E_2^+]^\ast \rightarrow \bar{E}_2 := p_0 \bar{p}_2 + \left( \frac{\theta_\epsilon^2 D_\lambda L_0}{4} \right)^2 - \frac{\theta_\epsilon^ D_\lambda L_0}{4\omega^2(y_0)} \quad \text{in} \quad L^\infty((0, T))
\]
and define the averaged environmental energy \( E_\epsilon^- := E_\epsilon^0 + \varepsilon^2 \bar{E}_2^\parallel \). The following theorem shows how the Hamiltonian character of the model problem and the thermodynamic interpretation materialise for the averaged total second-order energy correction \( \bar{E}_2 = \bar{E}_2^+ + \bar{E}_2^- \).

**Theorem 4.1.** Let \((y_0, p_0)\) be as in (19) and \((\bar{y}_2, \bar{p}_2)\) be as in Theorem 3.2. Let \( \bar{E}_2 \) be the averaged total second-order energy correction
\[
\bar{E}_2 = \bar{S}_2^\parallel (\bar{y}_2, \bar{p}_2; y_0, p_0) = \bar{A}(\bar{p}_2; y_0, p_0) + F_0(y_0) \bar{y}_2 + T_0(y_0) \bar{S}_2,
\]
with
\[
\bar{A}(\bar{p}_2; y_0, p_0) = p_0 \bar{p}_2 + \left( \frac{\theta_\epsilon^ \omega^\prime(y_0)}{4 \omega^2(y_0)} \right)^2 - T_0(y_0) \left( \frac{p_0 \omega^\prime(y_0)}{2 \omega^2(y_0)} \right)^2,
\]
and
\[
T_0(y_0) = \theta_\epsilon^ \omega^\prime(y_0), \quad F_0(y_0) = \theta_\epsilon^ \omega^\prime(y_0), \quad \bar{S}_2 = \bar{S}_2(y_0, p_0) = \frac{1}{2} \left( \frac{p_0 \omega^\prime(y_0)}{2 \omega^2(y_0)} \right)^2 + C_{\bar{S}_2},
\]
where
\[
C_{\bar{S}_2} = -\theta_\epsilon^ \frac{\omega^\prime(y_0)}{2 \omega^2(y_0)} - \frac{5 \theta_\epsilon^ \omega^\prime(y_0)^2}{16 \omega^3(y_0)} + \frac{p_0^2 \omega''(y_0)}{4 \omega^4(y_0)} - \frac{p_0^2 \omega'(y_0)^2}{4 \omega^4(y_0)}.
\]
Then, the differential equations (29c) and (29d) and the constituent equations (51) take the form
\[
\frac{d\bar{y}_2}{dt} = \frac{\partial \bar{E}_2}{\partial p_0}, \quad \frac{d\bar{p}_2}{dt} = \frac{\partial \bar{E}_2}{\partial y_0} \quad \text{and} \quad F_0 = \frac{\partial \bar{E}_2}{\partial \bar{y}_2}, \quad T_0 = \frac{\partial \bar{E}_2}{\partial \bar{S}_2}.
\]

**Proof.** The claim follows directly from (29c) and (29d).

**Remark.** We point out that (57) gives a thermodynamic interpretation of the slow second-order evolution derived in Theorem 3.2. Moreover, with the special initial values as in (55), one finds that \( \bar{E}_2 \equiv 0 \), in accordance with equation (9). In this special case, the second-order energy correction \( \bar{E}_2 (\bar{y}_2, \bar{p}_2, \bar{S}_2; y_0, p_0) \equiv 0 \) acts as a constraint on the system and \( \varepsilon^2 \) in the expansion can be regarded as a Lagrange multiplier. Additionally, note that the expression for \( \bar{S}_2 \) was chosen as the part of the averaged second-order energy correction that does not include the self-interaction with the averaged first-order correction and that corresponds to the appropriate expression found in \( E_2^+ \). Finally, note that the term
\[
T_0(y_0) \left( \frac{p_0 \omega^\prime(y_0)}{2 \omega^2(y_0)} \right)^2
\]
can be found both in \( A \) and in \( \bar{S}_2 \), which indicates an energy exchange of heat and work in the averaged total second-order energy correction \( \bar{E}_2 \).
5 Conclusion

In this paper, we analysed a simple fast-slow Hamiltonian system with energy function of the form

\[ E_\varepsilon(y_\varepsilon, z_\varepsilon) = \frac{1}{2}y_\varepsilon^2 + \frac{1}{4}z_\varepsilon^2 + \frac{1}{2}\varepsilon^{-2}(y_\varepsilon)z_\varepsilon^2, \]

where \( y_\varepsilon \) is the slow and \( z_\varepsilon \) is the fast degree of freedom and \( 0 < \varepsilon < \varepsilon_0 \) is a parameter determining the scale separation. This fast-slow Hamiltonian system was introduced and studied in [6], where a theory is established to describe the dynamics of \( y_\varepsilon \) in the limit \( \varepsilon \to 0 \), i.e., the coarse-grained dynamics of the system.

In the first part of this paper, we gave a finer description of the dynamics, for a small but non-zero \( \varepsilon \), by deriving the second-order correction of the system’s dynamical evolution. The second-order expansion can be decomposed into a highly oscillatory term with zero mean and a remainder; remarkably, the remainder can be characterised explicitly in form of a linear inhomogeneous system of differential equations as shown in Theorem 3.2. This gives in principle a computationally tractable way to simulate the dynamics efficiently.

Moreover, the expansion can be interpreted in a two-scale sense (see Appendix A). Furthermore, in Theorem 4.1 we provided a thermodynamic interpretation of the slow second-order evolution derived in Theorem 3.2.

In the second part of this paper, we investigated the fast subsystem with energy function

\[ E_\varepsilon^f(z_\varepsilon; y_\varepsilon) = \frac{1}{2}z_\varepsilon^2 + \frac{1}{2}\varepsilon^{-2}(y_\varepsilon)z_\varepsilon^2, \]

which we interpret as the system of a harmonic oscillator in which the frequency is slowly perturbed by \( y_\varepsilon \).

After appropriate scaling, the perturbation disappears in the limit \( \varepsilon \to 0 \), and the resulting system is a standard harmonic oscillator with one degree of freedom, which is a simple example of an ergodic Hamiltonian system. Hence, in the limit, we can regard the system studied here as a thermodynamic system evolving in a sequence of thermodynamic equilibrium states. (Here we use a setting developed by Hertz [10] which, despite being described beautifully in [5], seems little known, and is thus sketched in Appendix B.) Based on this observation, we defined for \( \varepsilon > 0 \) a temperature \( T_\varepsilon \), an external force \( F_\varepsilon \) and an entropy \( S_\varepsilon \) of the fast subsystem \( E_\varepsilon^f \).

Using the results from the first part of this paper, we expanded \( E_\varepsilon^f, T_\varepsilon, F_\varepsilon \) and \( S_\varepsilon \) and showed that the first and second law of thermodynamics (according to Carathéodory) are satisfied in the expansion of \( E_\varepsilon^f \). In particular, we found that the leading-order expansion of \( E_\varepsilon^f \) exhibits a constant entropy, \( dS_0 = 0 \), and hence describes an adiabatic thermodynamic process, as shown in [17].

\[ dE_0^\perp = F_0 dy_0 + T_0 dS_0 = F_0 dy_0. \]

The form of the entropy in this adiabatic limit is given in [17] by

\[ S_0 = \log(\theta_\ast) + C. \]

Moreover, we showed that the averaged second-order expansion of the fast subsystem \( E_\varepsilon^f \) defines a non-adiabatic process, characterised by a non-constant entropy, \( d\bar{S}_2 \neq 0 \), see [52]. Remarkably, this entropy satisfies the equation

\[ d\bar{E}_2^\perp = F_0 dy_2 + T_0 d\bar{S}_2, \]

which is only expected in thermal equilibrium \( \varepsilon \to 0 \), though it is shown here to hold true beyond that limit.

The non-constant entropy to second-order is given in [51] by

\[ \bar{S}_2 = \bar{\theta}_2 / \theta_\ast. \]

In summary, the limit process is described by an energy which is not the naïve energy that one obtains by setting \( z_\varepsilon \equiv 0 \), as shown by Bornemann [5], and is characterised by a constant entropy, while a nonconstant entropy appears only at second-order.

A Interpretation of the analytic expansion as two-scale convergence

The convergence results in Theorem 3.2 exhibit scale separations that are characteristic of the theory of two-scale convergence. In this appendix, we give a summary of the theory and introduce a nonlinear version of two-scale convergence which is used in Corollary 3.3.
A.1 Two-scale convergence

The theory of two-scale convergence was first introduced by Nguetseng \[15\]. We follow here the presentation in \[1\] and \[21\], though restricted to the one-dimensional case. We denote by \(S\) the set \(S := [0,1)\) equipped with the topology of the 1-dimensional torus, and identify any function on \(S\) with its \(S\)-periodic extension on \(\mathbb{R}\).

In general a bounded sequence \(\{u_\varepsilon\}\) of functions in \(L^2(\Omega)\) is said to weakly two-scale converge to \(u \in L^2(\Omega \times S)\), symbolically indicated by \(u_\varepsilon \rightharpoonup u\), if and only if

\[
\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(t) \psi(t, \varepsilon^{-1} t) \, dt = \int_{\Omega \times S} u(t, s) \psi(t, s) \, dt \, ds,
\]

for any smooth function \(\psi: \mathbb{R} \times \mathbb{R} \to \mathbb{R}\) which is \(S\)-periodic with respect to the second argument.

A.2 Two-scale decomposition

For any \(\varepsilon > 0\), one can decomposes a real number \(t \in \mathbb{R}\) as \(t = \varepsilon[N(t/\varepsilon) + R(t/\varepsilon)]\), where

\[
N(t) := \max\{n \in \mathbb{Z} : n \leq t\}, \quad R(t) := t - N(t) \in \mathcal{S}.
\]

If \(\varepsilon\) is the ratio between two disparate scales, \(N(t/\varepsilon)\) and \(R(t/\varepsilon)\) may then be regarded as a coarse-scale and a fine-scale variable, respectively. Besides this two-scale decomposition, one defines a two-scale composition function:

\[
h_{\varepsilon}(t, s) := \varepsilon N(t/\varepsilon) + \varepsilon s \quad \forall (t, s) \in \mathbb{R} \times \mathcal{S}, \quad \forall \varepsilon > 0.
\]

The two-scale composition function can be written as \(h_{\varepsilon}(t, s) = t + \varepsilon[s - R(t/\varepsilon)]\), and thus

\[
h_{\varepsilon}(t, s) \to t \quad \text{uniformly in } \mathbb{R} \times \mathcal{S}, \quad \text{as } \varepsilon \to 0.
\]

Definition A.1 (Two-scale convergence, \[21\]). Let \(S\) and \(h_\varepsilon\) be defined as above. A sequence of functions \(\{u_\varepsilon\}\) in \(L^p(\mathbb{R})\) with \(1 \leq p \leq \infty\) two-scale converges strongly respectively weakly (weakly star for \(p = \infty\)), denoted by \(u_\varepsilon \rightharpoonup u, u_\varepsilon \rightharpoonup^* u, u_\varepsilon \stackrel{\cdot}{\rightharpoonup} u\), respectively, to a limit \(u_0(t, s)\) in \(L^p(\mathbb{R} \times \mathcal{S})\) if it satisfies the following corresponding relation:

\[
\begin{align*}
u_\varepsilon \rightharpoonup u & \quad \text{in } L^p(\mathbb{R} \times \mathcal{S}) \iff u_\varepsilon \circ h_\varepsilon \rightharpoonup u \quad \text{in } L^p(\mathbb{R} \times \mathcal{S}), \quad \forall p \in [1, \infty]; \\
u_\varepsilon \rightharpoonup^* u & \quad \text{in } L^p(\mathbb{R} \times \mathcal{S}) \iff u_\varepsilon \circ h_\varepsilon \rightharpoonup^* u \quad \text{in } L^p(\mathbb{R} \times \mathcal{S}), \quad \forall p \in [1, \infty]; \\
u_\varepsilon \stackrel{\cdot}{\rightharpoonup} u & \quad \text{in } L^\infty(\mathbb{R} \times \mathcal{S}) \iff u_\varepsilon \circ h_\varepsilon \stackrel{\cdot}{\rightharpoonup} u \quad \text{in } L^\infty(\mathbb{R} \times \mathcal{S}).
\end{align*}
\]

For any domain \(\Omega \subset \mathbb{R}\), two-scale convergence in \(L^p(\Omega \times \mathcal{S})\) is then defined by extending functions to \(\mathbb{R} \setminus \Omega\) with vanishing value.

It is shown in \[21\] that this definition of two-scale convergence is equivalent to the definition first introduced in \[15\]. However, it is more versatile. In particular, it allows defining two-scale convergence in \(C^0\).

A.3 Two-scale convergence in \(C^0\)

Some modifications are needed to extend the definition of two-scale convergence in \[21\] to \(C^0\), for in general the function \(u_\varepsilon \circ h_\varepsilon\) is discontinuous with respect to \(t \in \mathbb{R}\) and \(s \in \mathcal{S}\), even if \(u_\varepsilon\) is continuous. One therefore replaces \(u_\varepsilon \circ h_\varepsilon\) by a continuous function, \(L_\varepsilon u_\varepsilon\), constructed via linear interpolation with respect to each argument. More precisely, for \((t, s) \in \mathbb{R} \times \mathcal{S}\) and \(w: \mathbb{R} \times \mathcal{S} \to \mathbb{R}\), we define

\[
\begin{align*}
(L_\varepsilon w)(t, s) := w[\varepsilon N(t/\varepsilon), s] + R(t/\varepsilon)[w(\varepsilon N(t/\varepsilon) + \varepsilon, s) - w(\varepsilon N(t/\varepsilon), s)], \\
(J_\varepsilon w)(t, s) := w(t, s) - s \left(\lim_{r \to 1^-} w(t, r) - w(t, 0)\right).
\end{align*}
\]

Then, for \(v: \mathbb{R} \to \mathbb{R}\), the linear interpolation is defined as

\[
L_\varepsilon v := (J \circ L_\varepsilon)(v \circ h_\varepsilon).
\]

Thus \(v \circ h_\varepsilon\) is piecewise constant with respect to \(t\), whereas \(L_\varepsilon v\) is piecewise linear and continuous with respect to \(t\) and periodic in \(s\), i.e.,

\[
\lim_{r \to 1^-} (L_\varepsilon v)(t, r) = (L_\varepsilon v)(t, 0) \quad \forall t \in \mathbb{R}.
\]

Note that if \(v \in C^0(\mathbb{R})\), then \(L_\varepsilon v \in C^0(\mathbb{R} \times \mathcal{S})\).

We say that \(u_\varepsilon\) strongly two-scale converges to \(u\) in \(C^0([0, T] \times \mathcal{S})\) if and only if

\[
L_\varepsilon u_\varepsilon \to u \quad \text{in } C^0([0, T] \times \mathcal{S}).
\]
A.4 Nonlinear two-scale convergence

The two-scale convergence theory is a generalisation of the weak* convergence theory which retains information about the oscillatory character of $u_\varepsilon$ in the limit $\varepsilon \to 0$. For instance, we have $\sin(2\pi \varepsilon^{-1} t) \overset{\varepsilon}{\to} \sin(2\pi s)$. Notice, however, that $\sin (2\pi \varepsilon^{-1} \phi(t)) \not\overset{\varepsilon}{\to} 0$ for any nonlinear function $\phi$. To derive a non-zero two-scale limit in such a case we introduce a nonlinear change of coordinates that temporarily annihilates the nonlinearity so that the standard two-scale limit can be taken before it is reintroduced into the two-scale limit. This procedure is expressed in the following definition. Note that the constant $\pi$ was chosen to normalise the period of the rapidly oscillating functions in Corollary 3.3.

**Definition A.2** (Two-scale convergence with respect to $\phi_0^{-1} \circ \pi$). Let $\{u_\varepsilon\} \subset C([0,T])$ and $u \in C([0,T] \times \mathcal{S})$. We say that $u_\varepsilon$ two-scale convergences with respect to $\phi_0^{-1} \circ \pi$ to $u$ in $C([0,T] \times \mathcal{S})$ if $u_\varepsilon \circ \phi_0^{-1} \circ \pi$ two-scale converges to $u \circ (\phi_0^{-1} \circ \pi, \text{Id})$ in $C([0,\pi^{-1} \phi_0(T)] \times \mathcal{S})$, i.e.,

$$
\frac{\phi_0^{-1}}{2} \sin(\pi \varepsilon) u \quad \text{in} \quad C([0,T] \times \mathcal{S}) \quad \iff \quad u_\varepsilon(\phi_0^{-1}(\pi t)) \overset{T}{\rightharpoonup} u(\phi_0^{-1}(\pi t), s) \quad \text{in} \quad C([0,\pi^{-1} \phi_0(T)] \times \mathcal{S}).
$$

With this definition at hand, we can express the uniform convergence results of Theorem 3.2 using the notation of two-scale convergence. Rephrasing the weak* convergence results in Theorem 3.2 in a similar way requires more notation. It is for this reason that we do not pursue the analysis any further.

B Hertz’ approach to thermodynamics

As the theory of Hertz does not seem to be very well known, we recall the thermodynamic setting and the theory here, following the presentation in [5].

**B.1 The first and second law of thermodynamics**

Hertz considers a thermodynamic system under a slowly changing external parameter $y$. A classical example is a vessel filled with gas, where $y$ indicates the height of a piston which compresses the gas. In line with Hertz’ analysis, we considered for the problem studied in this article the fast subsystem with energy $E^1_\varepsilon$ as a thermodynamic system under a slowly changing external parameter represented by $y_\varepsilon$. We point out that Hertz’ theory is based on dynamical systems which are inherently reversible in time and are thus regarded as idealised thermodynamic systems. As such, on a macro-scale level, the dynamics is described by the first and second law of thermodynamics, where the second law is given in Carathéodory’s form.

The first law states that for every infinitesimal thermodynamical process $dy$, one can introduce the work of an external force $dA = Fdy$ and the heat supply $dQ$ such that the sum $dA + dQ$ is the differential of some energy function $E$,

$$
dE = dA + dQ. \tag{54}
$$

The second law of thermodynamics states that, for reversible processes, there are two functions of state, namely the absolute temperature $T$ and the entropy $S$ such that

$$
dQ = TdS.
$$

Hence, the first and second law of thermodynamics combined read

$$
dE = Fdy + TdS. \tag{55}
$$

Equation (55) can be reduced to the statement that there exists an entropy $S = S(E, y)$ such that the constitutive equations

$$
\frac{1}{T} = \frac{\partial S(E, y)}{\partial E} \quad \text{and} \quad F = -T \frac{\partial S(E, y)}{\partial y} \tag{56}
$$

are satisfied.

The special case of a process without heat exchange, $dQ = 0$, is called an adiabatic process. In this case, all work $dA$ is converted into a change of energy,

$$
dE = dA, \tag{57}
$$

or, equivalently, the entropy of the system stays constant,

$$
S(E, y) = \text{const.} \tag{58}
$$

**Remark.** With $E = E(S, y)$ the constitutive equations (56) read equivalently

$$
T = \frac{\partial E(S, y)}{\partial S} \quad \text{and} \quad F = \frac{\partial E(S, y)}{\partial y}. \tag{59}
$$
B.2 Derivation of thermodynamics from mechanics

We will give a first intuitive and informal explanation of the macroscopic thermodynamic behaviour for microscopical mechanical systems of Hamiltonian nature. Let $H(z,\zeta; y)$ be a Hamiltonian, where $z$ and $\zeta$ denote the generalised coordinate and generalised momentum respectively, and where $y$ is an external parameter. If we divide the external parameter into a slowly varying component $s$ and a rapidly varying component $r$, then the time derivative of the Hamiltonian can be written as

$$\frac{dH}{dt} = \frac{\partial H}{\partial s} \frac{ds}{dt} + \frac{\partial H}{\partial r} \frac{dr}{dt}.$$  (60)

This equation expresses the balance of the energy on the micro-scale in the same way as the first law of thermodynamics does on the macro-scale. By comparing these two equations, one can reason that the last term in (60) with the heat supply of the system averaged over time to obtain the macro-scale effect of the micro-scale motion.

This informal and qualitative derivation of thermodynamic properties in Hamiltonian systems can be developed into a quantitative theory for ergodic Hamiltonian systems, as discussed in the following section.

B.3 Thermodynamic description of a slowly perturbed harmonic oscillator

We now sketch how Hertz’ theory makes the previous informal arguments precise in the case of an harmonic oscillator with slowly perturbed frequency. There, the dynamics of the generalised position $z_e$ and momentum $\zeta_e$ are governed by a Hamiltonian of the form

$$H^\perp_e(z_e,\zeta_e; y_e) = \frac{1}{2} q_e^2 + \frac{1}{2} \omega_e^2(y_e) z_e^2,$$  (61)

where $y_e(t) = y(\varepsilon t)$ is a slow external parameter with $\dot{y}_e = \mathcal{O}(\varepsilon)$. For $\varepsilon = 0$, the unperturbed Hamiltonian is given by

$$H^\perp_0(z_0,\zeta_0; y_\ast) = \frac{1}{2} q_0^2 + \frac{1}{2} \omega_\ast^2(y_\ast) z_0^2,$$  (62)

where $y_\ast(t) = y(0) = y_\ast$ is constant. Let the corresponding canonical equations be complemented by the initial values $z_0(0) = 0$ and $\zeta_0(0) = \sqrt{2E_\ast^\perp}$, where $E_\ast^\perp$ is a constant energy level such that $H^\perp_0(z_0(t),\zeta_0(t), y_\ast) \equiv E_\ast^\perp$. The solution of the unperturbed system is thus given by

$$z_0(t) = \frac{\sqrt{2E_\ast^\perp}}{\omega(y_\ast)} \sin(\omega(y_\ast)t), \quad \zeta_0(t) = \sqrt{2E_\ast^\perp} \cos(\omega(y_\ast)t).$$  (63)

We note that the unperturbed Hamiltonian $H^\perp_0$ is ergodic, as trajectories in phase-space coincide with the whole energy surface.

B.3.1 Derivation of $T$ and $S$ via time-averaging

For an ergodic Hamiltonian system, the temperature in thermal equilibrium is defined via the time average, indicated by angle brackets $\langle \cdot \rangle$, of twice the kinetic energy,

$$\left\langle \frac{\partial H^\perp_0}{\partial \zeta_0} \right\rangle,$$

relating the temperature to the “speed” of the system’s degrees of freedom. The temperature $T$ for the system (62) is hence of the form

$$T(E_\ast^\perp, y_\ast) := \left\langle \frac{\partial H^\perp_0(z_0,\zeta_0; y_\ast)}{\partial \zeta_0} \right\rangle := \lim_{\theta \to \infty} \frac{1}{2\theta} \int_{-\theta}^{+\theta} 2E_\ast^\perp \cos^2(\omega(y_\ast)t) \ dt = E_\ast^\perp.$$  (64)

The system’s entropy can then be derived from the first constitutive equation in (50), namely

$$S(E_\ast^\perp, y_\ast) = \log(E_\ast^\perp) + f(y_\ast),$$

where $f(y_\ast)$ is a constant of integration with respect to $E_\ast^\perp$. To find the function $f$, we use the second equation in (50), with the macro-scale external force $F$ defined as the time average of the micro-scale force:

$$F(E_\ast^\perp, y_\ast) := \left\langle \frac{\partial H^\perp_0(z_0,\zeta_0; y_\ast)}{\partial y_\ast} \right\rangle = E_\ast^\perp \frac{\omega(y_\ast)}{\omega(y_\ast)}.$$
Therefore

\[ S(E^+_z, y_*) = \log \left( \frac{E^+_z}{\omega(y_*)} \right) + C, \]

where \( C \) is an integration constant. Note that there are various definitions of entropy in the classical thermodynamic literature and \([10]\) coincides with a definition for infinitely large systems \([3, \text{Chapter 1.5}]\).

### B.3.2 Derivation of \( T \) and \( S \) via ensemble-averaging

In this subsection, we sketch the derivation of an equivalent expression for the entropy, \((\text{74})\) below, as given by Hertz, still for the perturbed harmonic oscillator. Since this section is largely a modern reformulation of \([10]\) applied to a special case, we only sketch the argument and dispense with rigour.

As the harmonic oscillator is ergodic, it admits a unique invariant measure, given by

\[ \mu(A) = \frac{\int_A \frac{d\sigma}{|\nabla H^+_0|}}{\int_{\Sigma} \frac{d\sigma}{|\nabla H^+_0|}}, \]

where \( A \subseteq \Sigma \) is a region on the level set \( \Sigma = \{(z_0, \zeta_0) \in \mathbb{R}^2 : H^+_0(z_0, \zeta_0; y_*) = E^+_z\} \), \( d\sigma \) is an area element on the energy surface and

\[ |\nabla H^+_0| = \left\{ \left( \frac{\partial H^+_0}{\partial z_0} \right)^2 + \left( \frac{\partial H^+_0}{\partial \zeta_0} \right)^2 \right\}^{1/2}. \]

By the ergodic theorem of Birkhoff and Khinchin, see, e.g., \([22]\), the invariant measure \( \mu \) can be used to find the time average in \((\text{64})\) simply by integration, without knowing the trajectory, since all the quantities on the right-hand side of equation \((\text{65})\) are known,

\[ T(E^+_z, y_*) = \left\langle \zeta_0 \frac{\partial H^+_0(z_0, \zeta_0; y_*)}{\partial \zeta_0} \right\rangle = \int_{\Sigma} \frac{\zeta_0 \partial H^+_0}{\partial \zeta_0} \frac{d\sigma}{|\nabla H^+_0|}. \]

The numerator can be evaluated by noting that \( \partial H^+_0 / \partial \zeta_0 \) is the second component of the vector \( \nabla H^+_0 \) and hence

\[ n_\zeta := \frac{\partial H^+_0 / \partial \zeta_0}{|\nabla H^+_0|}, \]

is the second component of the outer unit vector \( n = \frac{\nabla H^+_0}{|\nabla H^+_0|} \) on the energy surface. Therefore, we can write the numerator in the form

\[ \int_{\Sigma} \frac{\zeta_0 \partial H^+_0}{\partial \zeta_0} \frac{d\sigma}{|\nabla H^+_0|} = \int_{\Sigma} \zeta_0 n_\zeta \ d\sigma = \int_{H^+_0(z_0, \zeta_0; y_*) \leq E^+_z} d(z_0, \zeta_0) =: \Gamma(E^+_z, y_*), \]

which follows from Gauss’ theorem, where \( \Gamma(E^+_z, y_*) \) is the phase-space volume enclosed by the trajectory of \((\text{63})\) and is also known as the action of the orbit in Hamiltonian dynamics \([9]\). To derive the denominator in \((\text{67})\), we calculate the derivative of \( \Gamma(E^+_z, y_*) \) with respect to \( E^+_z \). We find

\[ \Gamma(E^+_z + \Delta E^+_z, y_*) - \Gamma(E^+_z, y_*) = \int_{E^+_z \leq H^+_0(z_0, \zeta_0; y_*) \leq E^+_z + \Delta E_z} \frac{d(z_0, \zeta_0)}{\Delta n \ d\sigma}, \]

where \( \Delta n \) is the distance between the energy surface \( H^+_0(z_0, \zeta_0; y_*) = E^+_z \) and \( H^+_0(z_0 + n \Delta n, \zeta_0 + n_\zeta \Delta n; y_*) = E^+_z + \Delta E^+_z \). A Taylor expansion gives \( \Delta n = \Delta E^+_z / |\nabla H^+_0| \), and hence

\[ \frac{\partial \Gamma(E^+_z, y_*)}{\partial E^+_z} = \int_{H^+_0(z_0, \zeta_0; y_*) = E^+_z} \frac{d\sigma}{|\nabla H^+_0|}. \]

Combining equations \((\text{67})\)–\((\text{70})\), the temperature \( T \) can thus be expressed in terms of the phase-space volume \( \Gamma(E^+_z, y_*) \),

\[ T(E^+_z, y_*) = \frac{\Gamma(E^+_z, y_*)}{\partial \Gamma(E^+_z, y_*) / \partial E^+_z}. \]

According to equation \((\text{65})\) we integrate \((\text{71})\) with respect to \( E^+_z \) and obtain as formula for the entropy,

\[ S(E^+_z, y_*) = \log \left( \frac{\Gamma(E^+_z, y_*)}{\partial \Gamma(E^+_z, y_*) / \partial E^+_z} \right) + f(y_*). \]
It remains to show that the function $f$ is constant. To see this, we investigate the dependence of $S$ on $y_*$ and will, similar as above, use equation (56). Employing again the Birkhoff–Kinchin Theorem, we calculate

$$F(E^+_*, y_*) = \left\langle \frac{\partial H^+_0(z_0, \zeta_0; y_*)}{\partial y_*} \right\rangle = \int \frac{\partial H^+_0}{\partial y_*} \frac{d\sigma}{|\nabla H^+_0|}. \quad (72)$$

For the numerator, we calculate the derivative of $\Gamma(E^+_*, y_*)$ with respect to $y_*$. Similarly as before, we have

$$\Gamma(E^+_*, y_* + \Delta y_*) - \Gamma(E^+_*, y_*) = \int_{H^+_0(z_0, \zeta_0; y_* + \Delta y_*) \leq E^+_*} d\{z_0, \zeta_0\} - \int_{H^+_0(z_0, \zeta_0; y_*) \leq E^+_*} d\{z_0, \zeta_0\}$$

$$\approx \int_{H^+_0(z_0, \zeta_0; y_*) = E^+_*} \Delta n \, d\sigma,$$

where $\Delta n$ is the distance between the energy surface $H^+_0(z_0, \zeta_0; y_*) = E^+_*$ and $H^+_0(z_0 + n_\zeta \Delta n, \zeta_0 + n_\zeta \Delta n; y_* + \Delta y_*) = E^+_*$. A Taylor expansion gives

$$\Delta n = -\frac{1}{|\nabla H^+_0|} \frac{\partial H^+_0}{\partial y_*} \Delta y_*$$

and we obtain

$$\frac{\partial \Gamma(E^+_*, y_*)}{\partial y_*} = \int \frac{\partial H^+_0}{\partial y_*} \frac{d\sigma}{|\nabla H^+_0|}. \quad (73)$$

Combining equations (70), (72) and (73) we obtain

$$F(E^+_*, y_*) = \left\langle \frac{\partial H^+_0}{\partial y_*} \right\rangle = -\frac{\partial \Gamma(E^+_*, y_*)}{\partial \Gamma(E^+_*, y_*)/\partial E^+_*}.$$

We thus find the desired formula for the entropy,

$$S(E^+_*, y_*) = \log \left\{ \Gamma(E^+_*, y_*) \right\} + C, \quad (74)$$

where $C$ is an arbitrary constant. This is a key result of Hertz: the entropy of a Hamiltonian system under the influence of a slowly varying parameter is, up to a constant, the logarithm of the phase space volume.

### B.4 Thermodynamic description of the model problem

In Section B.3, we derived thermodynamic properties of a perturbed harmonic oscillator in the limit of infinitesimal small perturbations. This case corresponds to a situation where the motion of the external parameter is infinitely slow and can thus be regarded as constant.

For the model problem §3, we expect to see thermodynamic effects as a description of the fast subsystem. Now, however, the slow parameter is not constant. We nevertheless derive a description, using a suitable mapping to the harmonic oscillator studied in Section B.3. To this behalf, let us now introduce a scaling that focuses on the dynamics of the slow parameter. Here, the external parameter will affect the system dynamically of order one, while the frequency of the harmonic oscillator becomes infinitely high.

The energy of the slowly perturbed harmonic oscillator in (61) is given by

$$E^+_\varepsilon(t) = \frac{1}{2} \xi^2(t) + \frac{1}{2} \omega^2(y(t)) z^2(t). \quad (75)$$

We introduce a scaling in space and time of the form

$$z_\varepsilon(t) = \varepsilon^{-1} z(t), \quad \xi_\varepsilon(t) = \xi(t) \quad \text{and} \quad \tau = \varepsilon t. \quad (76)$$

With this scaling, the new energy takes the form

$$\tilde{E}^+_\varepsilon(\tau) = \frac{1}{2} \xi^2_\varepsilon(\tau) + \frac{1}{2} \omega^2(\tilde{y}_\varepsilon(\tau)) \tilde{z}^2(\tau), \quad (77)$$

which corresponds to the energy of the fast subsystem in our model problem §3. This establishes the mapping between perturbed harmonic oscillator and the problem under consideration.

For (75), Section B.3 describes how to derive the temperature, entropy and external force in the limit $\varepsilon \to 0$. They are given by

$$T(E^+_*, y_*) = \frac{\Gamma(E^+_*, y_*)}{\partial \Gamma(E^+_*, y_*)/\partial E^+_*}, \quad S(E^+_*, y_*) = \log \left\{ \Gamma(E^+_*, y_*) \right\} + C, \quad F(E^+_*, y_*) = -\frac{\partial \Gamma(E^+_*, y_*)/\partial y_*}{\partial \Gamma(E^+_*, y_*)/\partial E^+_*}.$$
where the phase space volume is
\[ \Gamma(E^1_\varepsilon, y_\varepsilon) = 2\pi \frac{E^1_\varepsilon}{\omega(y_\varepsilon)}. \]

In analogy, we define in the case of (77) with a time-dependent external parameter \( y_\varepsilon \) and energy \( E^1_\varepsilon \) the temperature, entropy and external force as
\[ T_\varepsilon(E^1_\varepsilon, y_\varepsilon) := \frac{\Gamma_\varepsilon(E^1_\varepsilon, y_\varepsilon)}{\partial \Gamma_\varepsilon(E^1_\varepsilon, y_\varepsilon)/\partial E^1_\varepsilon}, \quad S_\varepsilon(E^1_\varepsilon, y_\varepsilon) := \log(\Gamma_\varepsilon(E^1_\varepsilon, y_\varepsilon)) + C_\varepsilon, \quad F_\varepsilon(E^1_\varepsilon, y_\varepsilon) := \frac{\partial \Gamma_\varepsilon(E^1_\varepsilon, y_\varepsilon)/\partial y_\varepsilon}{\partial \Gamma_\varepsilon(E^1_\varepsilon, y_\varepsilon)/\partial E^1_\varepsilon}, \]
where \( C_\varepsilon \) is an arbitrary constant and \( \Gamma_\varepsilon \) is the time dependent phase-space volume derived from (14),
\[ \Gamma_\varepsilon(E^1_\varepsilon, y_\varepsilon) = 2\pi \varepsilon \frac{E^1_\varepsilon}{\omega(y_\varepsilon)}. \]

Since entropy is an extensive property, it scales with the size, according to (75). To compare it with intensive quantities and to avoid a divergent entropy in the limit \( \varepsilon \to 0 \), the constant in the entropy has to be chosen accordingly, for example \( C_\varepsilon = -\log(\Gamma_\varepsilon(E^1_\varepsilon, y_\varepsilon)) \). With (14), the phase-space volume \( \Gamma_\varepsilon \) can be written as
\[ \Gamma_\varepsilon(t) = 2\pi \varepsilon \theta_\varepsilon(t) \]
and consequently with \( E^1_\varepsilon = \theta_\varepsilon \omega(y_\varepsilon) \) we obtain the desired final thermodynamic formulas in (11):
\[ T_\varepsilon = \theta_\varepsilon \omega(y_\varepsilon), \quad S_\varepsilon = \log(\theta_\varepsilon) + C_\varepsilon, \quad F_\varepsilon = \theta_\varepsilon \omega'(y_\varepsilon). \]
