Introduction

Epidemiological studies suggest that iron modulates the susceptibility to infections/inflammation, but the molecular mechanisms underlying this phenomenon are incompletely understood. The iron/inflammation relationship is reciprocal, since several iron-related molecules (TIR1, Fpn, ferritin, Lcn2, etc.) are transcriptionally modulated by inflammation [1]. Among them the anti-microbial peptide hepcidin, the main regulator of systemic iron homeostasis, is an acute phase protein expressed and secreted by the liver, which provides a critical connection with the inflammatory response [2]. Hepcidin expression in inflammation is activated by IL6 and IL22 [3] through phosphorylated Stat3 (P-Stat3) binding to the hepcidin promoter, in a region closed to the加州悍马疾病/California mouse/german macaque pathways differentially expressed in Tmprss6 KO mice, compared to IDA animals and thus irrespective of the iron status. In the effort of defining genes potentially targets of Tmprss6 we analyzed liver gene expression changes according to the genotype and independently of treatment. Tmprss6 inactivation causes down-regulation of liver pathways connected to immunity, and inflammatory response as well as spleen genes related to macrophage activation and inflammatory cytokines production. The anti-inflammatory status of Tmprss6 KO animals was confirmed by the down-regulation of pathways related to immunity, stress response and intracellular signaling in both liver and spleen after LPS treatment. Opposite to Tmprss6 KO mice, Hfe−/− mice are characterized by iron overload with inappropriately low hepcidin levels. Liver expression profiling of Hfe−/−/iron deficient versus iron loaded mice show the opposite expression of some of the genes modulated by the loss of Tmprss6. Altogether our results confirm the anti-inflammatory status of Tmprss6 KO mice and identify new potential target pathways/gene of Tmprss6.

Abstract

Control of systemic iron homeostasis is interconnected with the inflammatory response through the key iron regulator, the antimicrobial peptide hepcidin. We have previously shown that mice with iron deficiency anemia (IDA)-low hepcidin show a pro-inflammatory response that is blunted in iron deficient-high hepcidin Tmprss6 KO mice. The transcriptional response associated with chronic hepcidin overexpression due to genetic inactivation of Tmprss6 is unknown. By using whole genome transcription profiling of the liver and analysis of spleen immune-related genes we identified several functional pathways differentially expressed in Tmprss6 KO mice, compared to IDA animals and thus irrespective of the iron status. In the effort of defining genes potentially targets of Tmprss6 we analyzed liver gene expression changes according to the genotype and independently of treatment. Tmprss6 inactivation causes down-regulation of liver pathways connected to immunity, and inflammatory response as well as spleen genes related to macrophage activation and inflammatory cytokines production. The anti-inflammatory status of Tmprss6 KO animals was confirmed by the down-regulation of pathways related to immunity, stress response and intracellular signaling in both liver and spleen after LPS treatment. Opposite to Tmprss6 KO mice, Hfe−/− mice are characterized by iron overload with inappropriately low hepcidin levels. Liver expression profiling of Hfe−/−/iron deficient versus iron loaded mice show the opposite expression of some of the genes modulated by the loss of Tmprss6. Altogether our results confirm the anti-inflammatory status of Tmprss6 KO mice and identify new potential target pathways/gene of Tmprss6.

hepcidin) mice. These findings suggested that in vivo lack of hepcidin and not lack of iron induces a proinflammatory condition, when body iron is low [11]. However, the molecular pathway/s that account for the anti-inflammatory phenotype observed in Tmprss6 KO mice remain undefined.

The liver plays a crucial role in the response to systemic inflammation, via secretion of acute phase proteins and hepcidin production. For this reason we investigated the whole genome transcriptional profiling of the liver and the expression of selected genes in the spleen in Tmprss6 KO mice, which are iron deficient with high hepcidin, in comparison with iron deficient (IDA) animals, with low hepcidin levels. The latter approach was performed with the aim of identifying signaling pathway/s activated by chronic hepcidin overexpression and/or the genes connected with the anti-inflammatory response are up-regulated.

**Materials and Methods**

**Animals, Diet and Tissue Collections**

Mice were maintained in the animal facility of San Raffaele Scientific Institute in accordance with the European Union guidelines. The study was approved by the Institutional Animal Care and Use Committee (IACUC) of San Raffaele Scientific Institute, Milan, Italy. To study the liver gene expression profiling in the absence of Tmprss6, we used Tmprss6 KO mice and iron deficiency anemia (IDA) control littermates, as described by Pagani et al. [11]. Briefly, four weeks old KO male mice, on a mixed 129/Ola x C57BL/6 background [9], were fed an iron-balanced diet (carbonile iron 200 mg/kg, SAFE, Augy, France).

Four weeks old IDA animals were maintained on an iron-deficient diet (<3 mg iron/kg; SAFE) for 3 weeks. Inflammation was induced by intra-peritoneal injection of lipopolysaccharide (LPS) (from E.coli O26:B6; 0.1 mg/kg, i.p., Sigma-Aldrich, Sydney, Australia). Animals were sacrificed 6 hours later.

To investigate the role of exogenous hepcidin in the modulation of liver gene expression, seven weeks IDA mice were ip injected with 100 micrograms/animal of recombinant hepcidin or sterile PBS as vehicle. Mice were sacrificed 8 hours later.

To study liver gene expression modulation by dietary iron, four weeks old male mice were maintained on an iron balanced, iron deficient and iron loaded (8.3 g/kg iron, SAFE, Augy, France) diet for 3 weeks. Livers and spleen used for RNA isolation were stored in RNALater (Qiagen, Mississauga, ON, Canada) and processed for quantitative real-time PCR. Livers were also analyzed for total liver iron content (LIC) [11].

**Microarray Analysis**

The gene expression profile was determined using the MouseWG-6 v2 Expression BeadChips (Illumina®). On a single BeadChip it is possible to simultaneously profile six samples for more than 45,200 transcripts for each sample. In the first phase of the experiment, cDNA and cRNA synthesis was performed using the Illumina Total Prep RNA Amplification Kit (Ambion), according to the manufacturer’s protocol; briefly, 500ng of total RNA, isolated from liver tissue by using the RNeasy Mini Kit (QIAGEN), were reverse transcribed to cDNA with T7 Oligo(T) Primer, then the double strand cDNA was in vitro transcribed to synthesize cRNA using a biotin-NTP mix. The resulted cRNA was quantified by three replicate measurements using Nanodrop-2000 spectrophotometer and the quality assessed using the Agilent Bioanalyzer. 750 ng of cRNA (150 ng/µl) were then hybridized to the BeadChip at 58°C overnight and the fluorescent signal was developed with streptavidin-Cy3. BeadChips were then imaged using the Illumina® BeadArray Reader, a two-channel 0.8 µm resolution confocal laser scanner and the Illumina® GenomeStudio software. This software was used to elaborate the fluorescence signal to a value, whose intensity corresponds to the quantity of the respective transcript in the original sample. The same software was used to assess the system quality control, including biological specimen, hybridization, signal generation controls and negative controls.

Gene expression data were normalized using the cubic spline algorithm implemented in the Illumina® GenomeStudio software. More than 30,000 genes were investigated with the array experiment, of those a selection of “expressed” genes was done by filtering on the “detection P-Value” parameter. The transcripts whose intensity value was significantly different from that of background (detection P-Value <0.01) in at least one sample of the entire series were considered “expressed” genes in the experiment and on those the following analyses were performed. More than 10,000 genes were appointed as “expressed” in the experiment. PCA (Principal Component Analysis) was done on that group of genes using scripts in Rstudio [12]. LIMMA Bioconductor package [13] was used extract of differentially expressed genes considering a factorial design model and pair-wise comparisons. A post test was used to select putative differentially genes considering the following comparison (KO: Tmprss6 KO; IDA: Iron Deficiency Anemia; UT: untreated; LPS: LPS treatment).

The dotted line shows significance cut-off at enrichment analysis, which corresponds to a P-Value of 0.05. B) Representation of the KEGG Toll-Like Receptor Signaling Pathway, showing up-regulated (red boxes) and down-regulated (green boxes) genes. doi:10.1371/journal.pone.0069694.g003
KO.UT-IDA.UT.
KO.LPS-IDA.LPS.
IDA.LPS-KO.UT.
KO.LPS-KO.UT.
(KO.LPS-KO.UT)-(IDA.LPS-KO.UT) = Genotype.
(KO.LPS-KO.UT)-(IDA.LPS-KO.UT) = Interaction.
(KO.LPS-KO.UT)-(IDA.LPS-KO.UT) = Treatment.

A biological term enrichment analysis using Gene Ontology biological process database was performed using DAVID tool [14] [15] considering the background list of “expressed” genes and the single lists deriving from the differentially expressed genes in specific contrasts i.e.: Genotype, Interaction and the single pairwise comparisons in basal and stimulated conditions (KO.UT-IDA.UT, KO.LPS-IDA.LPS).

The enriched categories were selected for being enriched in comparison under investigation and not in the background of “expressed” genes. GoSemSim package [16] was used to calculate semantic distances among Gene ontology biological process terms and the results used to cluster the biological terms so grouping related categories using hierarchical clustering.

The same procedure of enrichment was done considering the KEGG pathway database [17] [18] and the DAVID server [14].

The microarray data were deposited in NCBI’s Gene Expression Omnibus public repository and are accessible through GEO Series accession number GSE46287 [19]. As additional validation of the functional profiling, a repeat analysis was carried out using Gene Set Enrichment Analysis (GSEA) [20] (GSEA Analysis S1).

**qRT-PCR**

Two/three micrograms of total RNA were retro-transcribed with the High Capacity CDNA Reverse Transcription Kit (Applied Biosystem), using Random Examers and RNase Inhibitor. Gene expression levels were measure by quantitative real-time PCR using the ABI7900 Real-Time PCR System (Applied Biosystem) using TaqMan Gene Expression Master Mix (Applied Biosystem). Primers used for qRT-PCR are in Table S4. The unpaired 2-tailed Student t test was used to analyze significant changes in gene expression levels (GraphPad Prism Version 5.0a). P-Values <0.05 were considered statistical significant.

**Mouse Immune Array v2.1**

RNA isolated from the spleen of IDA and Tmprss6 KO mice, treated or not with LPS, were retro-transcribed as described in the “qRT-PCR” section, pooled and analyzed by TaqMan qRT-PCR using a Mouse Immune Array v2.1 (Applied Biosystem), that

1: Log₂ratio refers to the contrast KO.UT-IDA.UT.

doi:10.1371/journal.pone.0069694.t001

**Figure 4. Heat map of selected genes (basal condition).** The heat map represents the hierarchical clustering of 49 genes being differentially expressed according to the “Interaction contrast” (adjusted P-Value < 0.05 and $| \log_{2}\text{ratio} | > 1$). The expression level of each gene has been standardized by subtracting the gene’s mean expression and then dividing by the standard deviation across all samples. This scaled expression value, denoted as the Row Z-score, is plotted in red-blue scale color, with red indicating high expression.

doi:10.1371/journal.pone.0069694.g004

**Figure 5. Analysis of liver BMP-SMAD, STAT3 and NF-kB proteins activation.** Livers were dissociated as described in the “Material and Methods” section; extracts were subjected to SDS-PAGE and Western Blot performed using anti-Phosphorylated-SMAD1/5/8 (P-SMAD), anti-Phosphorylated-STAT3 (P-STAT3), anti-NF-κB p65, and anti-NF-κB p65. Protein levels were quantified by densitometric analysis of P-SMAD, P-STAT3, NF-κB p100 and NF-κB p65 specific bands, normalized to actin. 1 and 2 refers to liver extracts from two different mice. The numbers under the panels indicate arbitrary densitometric unit.

doi:10.1371/journal.pone.0069694.g005
allows the evaluation of the expression of about 90 immune-related genes. Hprt1 was used as the housekeeping gene. Unpaired 2-tailed Student t test was used to analyze significant changes in gene expression levels (GraphPad Prism Version 5.0a). P-Values <0.05 were considered statistical significant.

Western Blot Analysis

Livers were lysed in lysis buffer (200 mM Tris-HCl, pH 8; 1 mM EDTA; 100 mM NaCl; 10% glycerol; 0.5% NP-40) containing a mixture of proteases (Sigma-Aldrich) and phosphatases (Roche) inhibitors. Protein extracts (80 μg) were diluted in Laemmli buffer, boiled 5 minutes, separated onto a 10% SDS-PAGE and then transferred to Hybond C membrane (Amersham Bioscience Europe GmbH) by standard Western blot technique. Blots were blocked with 5% nonfat milk in TBST (0.5 M Tris-HCl, pH 7.4; 0.15 M NaCl and 0.1% Tween 20), incubated overnight with anti-phospho-SMAD1/5/8 (1:1000; Cell signaling; Millipore), anti-phospho-STAT3 (1:1000; Cell Signaling), anti-NF-kB p100 (1:1000; Cell Signaling), anti-NF-kB p65 (1:200; Santa Cruz Biotechnology Inc.), anti-actin (1:5000; Sigma-Aldrich). After washing with TBST, blots were incubated 1 hour with relevant HRP-conjugated antiserum and developed using a chemoluminescent detection kit (ECL; Amersham Biosciences).

Results

To study the role of Tmprss6 in hepatic gene regulation, we performed whole genome expression profiling on individual livers of untreated and LPS-injected Tmprss6 KO vs control IDA mice. Although Tmprss6 KO mice show a more severe iron deficiency anemia than control mice (Hb 97+/−1.5 vs 126+/−4.4 g/L [11]), liver iron content is comparable in the two groups (106.8+/−14.4 in Tmprss6 KO mice vs 101.8+/−11.6 μg iron/g liver in IDA animals) and does not significantly change after LPS treatment, as already reported for iron deficient animals [11].

Principal Component Analysis [21] was performed on the subset of expressed genes in the experiment (see materials and methods for working definition of expressed genes). A tridimensional visualization of the first 3 principal components of the various mice groups (Figure 1) show that Tmprss6 KO mice formed a distinct group, illustrating the strong impact of Tmprss6 deletion on liver gene expression. A similar situation is maintained also in LPS treated animals, suggesting a different LPS response in the two groups of mice.

Figure 6. Genes differentially expressed under basal conditions. Total liver RNA was isolated from Tmprss6 KO and IDA mice. mRNA expression was quantified by TaqMan qRT-PCR. Hprt1 was used as the housekeeping gene. mRNA expression ratio was normalized to an IDA mean value of 1. Error bars indicate Standard Error.; ns, not significant; *P<0.05; **P<0.01; and ***P<0.001. White bar: IDA mice; grey bar: Tmprss6 KO mice. doi:10.1371/journal.pone.0069694.g006

Figure 7. Genes differentially expressed after LPS treatment. Total liver RNA was isolated from Tmprss6 KO and IDA mice treated with LPS to induce acute inflammation (3 mice each group). TaqMan qRT-PCR was used to quantify mRNA expression and Hprt1 was used as the housekeeping gene. mRNA expression ratio was normalized to an IDA mean value of 1. Error bars indicate Standard Error.; ns, not significant; *P<0.05; **P<0.01; and ***P<0.001. White bar: IDA mice; grey bar: Tmprss6 KO mice. doi:10.1371/journal.pone.0069694.g007
To identify genes differentially expressed in the absence of Tmprss6 we used the LIMMA Bioconductor package [13]. The “Genotype contrast” identifies genes differentially expressed in Tmprss6 KO mice compared to wild-type animals, independently of the LPS treatment. The “Treatment contrast” recognizes genes differentially regulated by the LPS treatment, independently of the genotype, whereas the “Interaction contrast” identifies genes whose expression levels are influenced by both the absence of Tmprss6 and LPS treatment (Table S1).

Genes selected using a cut-off of adjusted P-Value $<0.05$ and $|\text{log}_{2}\text{ratio}| >1$ applying the “Genotype contrast” are shown in Dataset S1. The reliability of the method was confirmed by the selection of BMP-Son of Mother Against Decapentaplegic (SMAD) target and Tmprss6 genes. The term enrichment analysis of the genes emphasized the biological processes affected by the loss of Tmprss6; these comprise genes related to cytokine production, immune response to microorganisms, regulation of innate immune response and proliferation and differentiation of inflammatory cells (Figure 2). Enriched signaling pathways are shown in Figure 3A and include pathways involved in Toll like receptor signaling (KEGG pathway: mmu04620; Figure 3B), cytokine-cytokine receptor interaction (KEGG pathway: mmu04060; Figure S1) and nitric oxide metabolism (KEGG pathway: mmu00910; not shown). More in detail, loss of Tmprss6 modulates genes of the cytochrome-dependent drug metabolism

Figure 8. Heat map of clustered biological terms highlighted by differentially expressed genes in the “Interaction contrasts”. The heat map represents semantic similarity among gene ontology (GO) Biological Process (BP) terms. Rows and columns show the list of enriched GO BP terms derived from term enrichment analysis of Interaction significant genes. The colors represent the semantic distances calculated using GOSemSim Bioconductor package. Yellow-red clusters identify groups of terms sharing semantic similarity about biological processes.
doi:10.1371/journal.pone.0069694.g008
Figure 9. Heat map of selected genes (“Interaction contrast”). The heat map represents the hierarchical clustering of 59 genes being differentially expressed according to the “interaction contrast” (adjusted P-value < 0.05 and |log2ratio| > 1). The expression level of each gene has been standardized by subtracting the gene’s mean expression and then dividing by the standard deviation across all samples. This scaled expression value, denoted as the Row Z-score, is plotted in red-blue scale color, with red indicating high expression.

doi:10.1371/journal.pone.0069694.g009

(as Cyp1a2, Cyp2b13, Cyp2b20, Cyp2b9, Cyp2c54, Cyp3a25, Cyp4a12, Cyp4b1, Cyp4f14, Cyp7a1, Cyp7b1; KEGG pathway: mmm00980), up-regulates extracellular matrix-related genes (as Lamb3, Lamal, Wnt, Cnd1, Chd1), whereas down-regulates genes involved in the response to inflammation, as Lyp, Gsf14, Tlr2, Myd88, Nkhd2 (and target genes), genes encoding for members of the chemokine ligands (as Cxcl1, Cxcl2, Cxcl9, Cxcl10) and members of the interleukine receptors (as Il1r2, Il1r4, Il1r1, and Il6rba) [Dataset S1].

Genes selected according to the “Genotype contrast” and significantly modulated in Tmprss6 KO mice under basal condition are shown in Table S1. A selection of genes using a |log2ratio| > 1.5 is depicted in Table 1 and Figure 4. Up-regulation of BMP-SMAD-target genes, such as Hamp and Id1, was previously reported in Pagani et al. [11]. Our microarray data indicate that also Hamp2, Id2, Atf6 and Smad6 are up-regulated [Dataset S1]. In agreement with the activation of the BMP-SMAD pathway, phosphorylation of SMAD1/5/8 proteins is increased in Tmprss6 KO livers compared to IDA mice (Figure 5).

Variation of expression of representative genes (Table 1) was confirmed by qRT-PCR. Expression of Gdf15, Atf3, Efnal, Cdx1, Apol4 and Jun was increased (Figure 6), and expression of C9, that participates in the formation of Membrane Attack Complex and plays a key role in innate and adaptive immune response, was decreased. Mip3 that encodes for major urinary protein 3, showed a trend towards reduction in Tmprss6 KO mice (Figure 6).

The expected strong impact of LPS on liver gene expression is shown in Figure S2. Genes modulated according to the “Treatment contrast” are related to the inflammatory response, the regulation of defense and innate immune response, cytokines production, response to DNA damage, antigen presentation and processing, T cell activation, response to viruses, bacteria and peptidoglycan, ion transport and hair cycle and follicle development.

Fewer genes are modulated by LPS treatment in Tmprss6 KO mice compared to IDA animals (Table S1). Results of relevant genes, selected according to the “Genotype contrast” and with a |log2ratio| > 1.5 for LPS treatment are summarized in Table 2 and Figure S3. Selected genes, analyzed by qRT-PCR, are shown in Figure 7. Although the expression levels of these genes do not change under basal conditions (data not shown), their LPS-mediated activation is strongly impaired in Tmprss6 KO mice. Cyp2b9, Slc2a2, Fbxo21 and Fos are up-regulated in Tmprss6 KO animals. Interestingly, the F-box protein family, that includes also Fbxo21, is involved in Iron Regulatory Protein 2 degradation by proteasome during iron-replete condition through phosphorylation-dependent ubiquitination [22,23]. Genes involved in the regulation of the inflammatory response, as Nkhd1, Thr2, Icam1, Tnfaip2 and Il1r1, are strongly down-regulated in Tmprss6 KO mice. Due to the blunted LPS response and the reduced leukocytes recruitment in Tmprss6 KO animals [11] we analyzed the expression of liver genes involved in these signaling pathways. As shown in Figure 7, Cxcl1, Irak3, Myd88 and Soc3 are reduced in LPS-treated Tmprss6 KO animals, confirming the impairment of the TLR-mediated signaling pathway. This evidence is further supported by the reduced expression of Cd80, implying the impairment of NF-kB and Stat signaling in mutant mice [24].

Using anti-P-Stat3, we showed that Stat3 signaling was strongly decreased in Tmprss6 KO mice both under basal condition and after LPS injection (Figure 5), whereas no changes were observed at the mRNA level (Figure 7D). Of the two NF-kB key signaling molecules (p100 and p65) only p100 is decreased in Tmprss6 KO animals, suggesting a mild impairment of the pathway (Figure 5). The “Interaction contrast” was applied to examine to what extent the genotype influences the inflammatory response and biological term enrichment analysis highlighted the LPS-related
Figure 10. Modulation of representative genes by iron/hepcidin. 7 weeks old mice (n = 4 per group) were maintained an iron deficient (IDA, white bar), iron balanced (IB, light grey bar) and iron loaded (IL, dark grey bar) diet for 3 wks. Liver mRNA expression was measured by TaqMan qRT-PCR. Hprt1 was used as the housekeeping gene. mRNA expression ratio was normalized to an IB mean value of 1. Error bars indicate Standard Error; ns, not significant; *P<0.05 and **P<0.01.

doi:10.1371/journal.pone.0069694.g010
biological processes modified by the absence of Tmprss6 (Figure 8). These include signaling pathways related to innate immune and defense responses (Relb and Nfkbia), production of pro-inflammatory cytokines (as Cxcl2, Cxcl12, Il1r2, Il1ra, Tnfalpha2 and Tnfaip3), response to bacteria and peptidoglycan (as Tvl2). Interestingly, genes specifically modulated in Tmprss6 KO mice are Hmox1, as expected, but also Gdf15, Cyp7a1, the liver specific heme enzyme that synthesizes bile acid from cholesterol, and Prss8, which encodes for prostatin, a GPI-anchored serine protease belonging to the type II transmembrane serine proteases as Tmprss6 (Figure 9).

Expression of Immune Genes in Total Spleen of Tmprss6 KO and IDA Mice

Together with the liver, spleen macrophages are the principal mediators of the inflammatory-anti-inflammatory response. We investigated the expression of immune-related genes in spleen of IDA and Tmprss6 KO mice, treated or not with LPS by using the Mouse Immune Array v2.1 (AB) which allows testing >90 immune genes. Results of relevant genes selected using a cut off value of |log2ratio| >1.5 are shown in Table S2.

Compared to IDA, Tmprss6 KO mice under basal condition up-regulate transferrin receptor 1 (Tfrc) and the anti-inflammatory gene Bcl2l1, whereas down-regulate several pro-inflammatory genes, in particular Il1beta, Tnf alpha, the hematopoietin cytokine family (Il4 and Il13) and Cd40lg, which belongs to the “cytokine-cytokine receptor interaction” family. Compatible with a blunted response to LPS, nitric oxide synthase 2 (Nos2), pro-inflammatory cytokines (Il6 and Il1g), the chemokine ligand Cxcl11, and molecules involved in the positive regulation of the inflammatory response (Pig2 or Cx3c-2), are down-regulated in Tmprss6 KO mice. On the other hand, few immune genes as Bcl2l1, Hmox1 and Tfrc are up-regulated after LPS in Tmprss6 KO mice.

To investigate whether the transcriptional changes observed in KO vs IDA spleens, after LPS challenge, were due to different basal expression levels, expression fold changes were evaluated in the two groups of mice. Most of the spleen immune genes were up-regulated at similar levels in the two groups whereas few were down-regulated in KO compared to IDA animals (Figure S4A). Cyt2, Hmox1, Vegfa and Tfrc showed opposite regulation (up in KO and down in IDA) (Figure S4B).

Potential Tmprss6 Target Genes

In the attempt to distinguish whether high hepcidin or lack of Tmprss6 determines the anti-inflammatory phenotype, we used different approaches. First we injected IDA mice with hepcidin and analyzed the expression of differentially modulated genes (Table 1). Acute hepcidin treatment strongly decreases Gdf15, Afp3, and Efna1 expression 8 hours post-injection. C9 is only slightly down-regulated, whereas Apor4 is increased by hepcidin injection (Figure S5). To investigate the modulation of the same genes in chronic conditions of low and high hepcidin, we studied their liver expression in iron deficient (IDA), iron balanced (IB) and iron loaded (IL) wild type mice. As expected, hepcidin was down- and up-regulated in iron deficiency and overload respectively, and genes such as Ccd1 and Apor4 were modulated according to the iron/hepcidin levels (Figure 10), as already reported [25]. However, Gdf15, Afp3, Efna1, Jun and C9 expression remained unchanged even in IL mice, excluding that high hepcidin is responsible for variation of these genes in Tmprss6 KO mice (Figure 10).

Discussion

Hepcidin is a liver “defensin-like” acute phase protein with antimicrobial activity in vitro and potentially in vivo due to its ability to decrease plasma iron, a growth factor for invading pathogens. In response to inflammation, not only liver but also macrophages strongly increase hepcidin production, amplifying iron retention through the autocrine effect of hepcidin on macrophage ferroportin [26]. The inflammation-mediated hepcidin regulation has clinical relevance, since macrophage iron sequestration results in iron restricted erythropoiesis and Anemia of Chronic Disease (ACD), a common type of anemia observed in infections and acute and chronic inflammatory disorders as an adaptation mechanism. The anti-inflammatory role of hepcidin might not only be limited to intracellular iron sequestration. Changes in hepcidin (and/or of iron levels) might modulate the inflammatory response in vivo. Although the kinetics and doses of LPS were different in the different experimental settings, mouse models characterized by low hepcidin and iron overload, as Hfe−/− [27] and hepcidin−/− mice [6], up-regulate inflammatory genes in response to LPS more actively than wild type animals. Moreover, IL6 treatment of liver conditional Smad4 deficient mice [28] strongly induced liver acute phase proteins expression (Cyp and Saa-1), compared to control animals. On the contrary, Tmprss6 KO mice, characterized by iron deficient anemia and high hepcidin, have a blunted inflammatory response compared to mice with a diet-induced iron deficient anemia and low hepcidin [11].

The genome-wide expression profiling of Tmprss6 KO mice, compared to IDA animals, revealed the downregulation of genes involved in immune response, suggesting that high hepcidin and/or absence of Tmprss6 are associated with an anti-inflammatory phenotype. The evidence of a decreased STAT3 and NF-kB signaling, both at RNA and protein levels, further supports this finding, strengthening the pro-inflammatory role of Tmprss6, compatible with the finding of a pro-inflammatory condition in iron deficiency anemia [11], a condition characterized by Tmprss6 activation [29] [30]. As additional validation of this profiling, a further analysis has been carried out using the Gene Set Enrichment Analysis (GSEA) [20]. Gene sets related to inflammation and immune response are significantly enriched among the negative correlated genes (GSEA Analysis S1).

Liver gene expression profile of Tmprss6 KO mouse is available in the literature [9], however the experiment was performed on a single animal using a wild type liver replete animal as control, and thus is not comparable to our analysis.

Due to the genetic loss of the BMP pathway physiological inhibitor [31], some BMP-SMAD target genes are up-regulated in Tmprss6 KO mice. Indeed in these mice we show an increased phosphorylation of SMAD1/5/8, expected to be low in conditions of iron deficiency. Other up-regulated genes, such as Gdf15, Afp3 and Jun, are linked to an anti-inflammatory response. Gdf15, a secreted member of the transforming growth factor (TGF)-beta superfamily highly expressed in liver tissue and in erythroid precursors, is commonly up-regulated during inflammation and exerts its function through phosphorylation of SMAD2 and SMAD3 [32]. Gdf15 inhibits leukocyte integrin activation thus reducing inflammatory cell recruitment after myocardial infarction [33], a finding in agreement with the reduced leukocytes recruitment observed in LPS-treated Tmprss6 KO mice [11]. Although Gdf15 is activated by inflammation, Tmprss6 KO mice do not show increased inflammatory cytokines, suggesting that in these mice Gdf15 is up-regulated by an inflammation-independent mechanism. Gdf15 has been proposed also as a hepcidin inhibitor [34]. However, the high hepcidin levels suggest that either Tmprss6
KO mice lack Gdf15 target molecule(s) or that Gdf15 does not inhibit hepcidin in vivo, as recently proposed [35]. Af53 is a member of the Activation Transcription Factor family, which represses IL-6, IL-12 and other cytokines downstream Toll-like receptor 4 (TLR4) and provides a negative feedback to prevent excessive inflammation [36]. Af53 is activated by inflammation and by the TGF-beta mediator Smad3 [37], suggesting a functional connection with Gdf15.

The transcription factor Jun participates with other proteins (Fos, ATF and JDP) in the formation of activator protein 1 (AP-1) complex, essential in regulating gene expression in response to a variety of stimuli as cytokines, growth factors, stress, and infections. Functional cross-talk between TGF-beta, SMAD proteins and Jun has been demonstrated: the SMAD3/SMAD4 heterodimer acts synergistically with the Jun/Fos heterodimer to activate transcription in response to TGF-beta [38]. This finding is of interest since Gdf15, Af53 and Jun, all participate to the AP-1 complex formation.

In the attempt to distinguish whether the observed transcriptional changes are due to the genetic loss of Tmprss6 and/or to the differential regulation of the BMP-SMAD-target genes, as hepcidin, we analyzed the expression of some representative genes (Figure 10 and Figure S5) in conditions of acute and chronic high hepcidin. Acute hepcidin injection in IDA mice does not substantially change the expression of the studied genes, and even strongly down-regulates Gdf15 and Jun. Dietary iron loaded mice with chronic high hepcidin do not modulate the expression of the representative genes, excluding a role for hepcidin in their regulation.

Our approach of comparing Tmprss6 KO mice with IDA animals eliminates the contribution of iron deficiency to the modulation of gene expression. This allows an interesting comparison with published data on the opposite model of Hfe hemochromatosis [25]. The liver expression profiling of the Hfe\(^{-/-}\) mice was analyzed versus iron-loaded animals, excluding transcriptional changes due to iron overload. Comparing Tmprss6 KO and Hfe\(^{-/-}\) liver transcriptomes reveals interesting opposite expression of specific genes, as shown in Table S3. First, some inflammation related genes, such as Il6ra and acute phase proteins (Mmap4, Saa1, Saa2, Saa3), down-regulated or unchanged in Tmprss6 KO mice are up-regulated in Hfe\(^{-/-}\) mice. On the contrary, Hmp1, genes participating to the stress response (Egr1 and Gadd45g) and immune genes (suppressors of cytokine signaling and histocompatibility class II Ag) are down-regulated in Hfe\(^{-/-}\) but not in Tmprss6 KO animals. Considering that the BMP-SMAD pathway is attenuated in Hfe\(^{-/-}\) [39] and strongly activated in Tmprss6 KO mice it is tempting to speculate that these differences are related to the activity of this pathway. Further studies are needed to verify this hypothesis.
