Unitary and Euclidean Representations of a Quiver

Vladimir V. Sergeichuk
Institute of Mathematics, Tereshchenkivska 3, Kiev, Ukraine
sergeich@imath.kiev.ua

Abstract

A unitary (Euclidean) representation of a quiver is given by assigning to each vertex a unitary (Euclidean) vector space and to each arrow a linear mapping of the corresponding vector spaces. We recall an algorithm for reducing the matrices of a unitary representation to canonical form, give a certain description of the representations of canonical form, and reduce the problem of classifying Euclidean representations to the problem of classifying unitary representations. We also describe the set of dimensions of all indecomposable unitary (Euclidean) representations of a quiver and establish the number of parameters in an indecomposable unitary representation of a given dimension.

1 Introduction

Many problems of linear algebra can be formulated and studied in terms of quivers and their representations, which were proposed by Gabriel [1] (see also [2]). A quiver is a directed graph. Its representation $\mathcal{A}$ is given by assigning to each vertex $i$ a vector space $\mathcal{A}_i$ and to each arrow $\alpha : i \to j$ a linear mapping $\mathcal{A}_\alpha : \mathcal{A}_i \to \mathcal{A}_j$. For example, the canonical form problems for representations of the quivers $\xrightarrow{\bullet}$ and $\xrightarrow{\bullet}$ correspond to the canonical
form problems for linear operators (whose solution is the Jordan normal form) and for pairs of linear mappings from one space to another (the matrix pencil problem, solved by Kronecker).

In this chapter we study unitary and Euclidean representations of a quiver up to isometry. A unitary (Euclidean) representation $\mathcal{A}$ is given by assigning to each vertex $i$ a finite dimensional unitary (Euclidean) space $\mathcal{A}_i$ and to each arrow $\alpha : i \to j$ a linear mapping $\mathcal{A}_\alpha : \mathcal{A}_i \to \mathcal{A}_j$. We say that two unitary (Euclidean) representations $\mathcal{A}$ and $\mathcal{B}$ are isometric and write $\mathcal{A} \simeq \mathcal{B}$ if there exists a system of isometries $\Phi_i : \mathcal{A}_i \to \mathcal{B}_i$ such that $\Phi_j \mathcal{A}_\alpha \Phi_i^{-1} = \mathcal{B}_\alpha$ for each $\alpha : i \to j$.

Our main tool is Littlewood’s algorithm [3] for reducing matrices to triangular canonical form via unitary similarity. In [4] I rediscovered Littlewood’s algorithm and applied it to the canonical form problem for unitary representations of a quiver. Various algorithms for reducing matrices to different canonical forms under unitary similarity were also proposed by Brenner, Mitchell, McRae, Radjavi, Benedetti and Gragnolini, and others; see Shapiro’s survey [5].

In Section 2 we recall briefly Littlewood’s algorithm and study the structure of canonical matrices much as it was made in [4] for the matrices of linear operators in a unitary space.

We say that a matrix problem is unitarily wild if it contains the problem of classifying linear operators in a unitary space. In Section 2.3 we show that the last problem contains the problem of classifying unitary representations of an arbitrary quiver (i.e., it is hopeless in a certain sense) and give examples of unitarily wild matrix problems.

The vector

$$\dim \mathcal{A} = (\dim \mathcal{A}_1, \dim \mathcal{A}_2, \ldots, \dim \mathcal{A}_p) \in \mathbb{N}_0^p$$

is called the dimension of a representation $\mathcal{A}$ of a quiver $Q$ with vertices $1, 2, \ldots, p$ (we denote

$$\mathbb{N} = \{1, 2, \ldots\}, \quad \mathbb{N}_0 = \{0, 1, 2, \ldots\}.$$  

In Section 3 we describe the set of dimensions of direct-sum-indecomposable unitary representations of a quiver, and establish the number of parameters in an indecomposable unitary representation of a given dimension. Analogous, but much more fundamental and complicated, results for non-unitary
representations of a quiver were obtained by V. G. Kac [6, 7, 8] (see also [2, Sect 7.4]).

In particular, if \( z \in \mathbb{N}^p \) and \( Q \) is a connected quiver other than \( \bullet \) and \( \bullet \rightarrow \bullet \), then there exists an indecomposable unitary representation of dimension \( z \) if and only if \( zM_Q \geq z \), where \( M_Q = [m_{ij}] \) is the \( p \times p \) matrix whose entry \( m_{ij} \) is the number of arrows of the form \( i \rightarrow j \) and \( i \leftarrow j \), where

\[
(t_1, \ldots, t_p) \geq (z_1, \ldots, z_p)
\]

means

\[
t_1 \geq z_1, \ldots, t_p \geq z_p.
\]

In Section 4 we study Euclidean representations of a quiver. Let \( A^C \) denote the unitary representation obtained from a Euclidean representation \( A \) by complexification (\( A \) and \( A^C \) are given by the same set of real matrices). In Section 4.1 we prove intuitively obvious facts that

(i) \( A^C \simeq B^C \) implies \( A \simeq B \), and

(ii) if \( A \) is indecomposable and \( A^C \) is decomposable, then \( A^C \simeq U \oplus \bar{U} \),

where \( U \) is an indecomposable unitary representation.

This will imply that unitary and Euclidean representations have the same sets of dimensions of indecomposable representations.

In Section 4.2 we study, when a given unitary representation of a quiver can be obtained by complexification. In particular, let \( A \) be a complex matrix that is not unitarily similar to a direct sum of matrices, and let \( S^{-1}AS = \bar{A} \) for a unitary matrix \( S \) (such \( S \) exists if \( A \) is unitarily similar to a real matrix). Then \( A \) is unitarily similar to a real matrix if and only if \( S \) is symmetric.

2 Unitary matrix problems

We suppose that the complex numbers are lexicographically ordered:

\[
a + bi \leq a' + b'i \text{ if either } a = a' \text{ and } b \leq b', \text{ or } a < a';
\]

and that the set of blocks of a block matrix \( A = [A_{ij}] \) are linearly ordered:

\[
A_{ij} \leq A_{i'j'} \text{ if either } i = i' \text{ and } j \leq j', \text{ or } i > i'.
\]
A block complex matrix with a given (perhaps empty) set of marked square blocks will be called a *marked block matrix*; a square block is marked by a line along its principal diagonal. By a *unitary matrix problem* we mean the classification problem for marked block matrices

\[ A = [A_{ij}], \quad 1 \leq i \leq l, \quad 1 \leq j \leq r, \]

up to transformations

\[ A \mapsto B := R^{-1}AS = [R^{-1}_{i}A_{ij}S_{j}], \quad (3) \]

where

\[ R = R_{1} \oplus \cdots \oplus R_{l}, \quad S = S_{1} \oplus \cdots \oplus S_{r} \]

are unitary matrices, and \( R_i = S_j \) whenever the block \( A_{ij} \) is marked. The transformation (3) is called an *admissible transformation*; we say that these marked block matrices \( A \) and \( B \) (with the same disposition of marked blocks) are *equivalent* and write \( A \sim B \) or \( (R, S) : A \sim B. \) (4)

Notice that a matrix consisting of a single block is reduced by transformations of unitary similarity if the block is marked, and by transformations of unitary equivalence otherwise. Moreover, the matrices of every unitary representation \( \mathcal{A} \) of a quiver can be placed into a marked block matrix \( A \) such that the admissible transformations with \( A \) correspond to reselections of the orthogonal bases in the spaces of \( \mathcal{A} \), for example,

\[
\begin{array}{ccc}
S_1 & S_2 & S_3 \\
S_{1}^{-1} & & \\
& A_{\lambda} & A_{\mu} & A_{\nu} \\
& 0 & A_{\xi} & \\
S_{3}^{-1} & & 0 \\
\end{array}
\]  

(5)

### 2.1 An algorithm

The algorithm is based on the following two lemmas:
Lemma 2.1. (a) Each complex matrix $A$ is unitarily equivalent to the matrix

$$D = a_1 I + \cdots + a_{k-1} I + 0, \quad a_i \in \mathbb{R}, \quad a_1 > \cdots > a_{k-1} > 0. \quad (6)$$

(b) If $R^{-1}DS = D'$, where $R$ and $S$ are unitary matrices and $D, D'$ are of the form (6), then $D = D'$,

$$S = S_1 \oplus \cdots \oplus S_{k-1} \oplus S',$$

and

$$R = S_1 \oplus \cdots \oplus S_{k-1} \oplus R',$$

where each $S_i$ has the same size as $a_i I$.

Lemma 2.2. (a) Each square complex matrix $A$ is unitarily similar to the block-triangular matrix

$$F = \begin{bmatrix}
\lambda_1 I & F_{12} & \cdots & F_{1k} \\
\lambda_2 I & \cdots & F_{2k} \\
\vdots & \ddots & \vdots \\
0 & & \lambda_k I
\end{bmatrix}, \quad \lambda_1 \geq \cdots \geq \lambda_k \quad (see (1)),$$

the columns of $F_{i,i+1}$ are linearly independent if $\lambda_i = \lambda_{i+1}$.

(b) If $S^{-1}FS = F'$, where $S$ is a unitary matrix and $F$ and $F'$ have the form (7), then $\lambda_i I = \lambda'_i I$ and

$$S = S_1 \oplus \cdots \oplus S_k,$$

where each $S_i$ has the same size as $\lambda_i I$.

Proof. These lemmas were proved in many articles, see, for example, [3, 4, 5], so we give only an outline of their proofs. Part (a) of Lemma 2.1 is the singular value decomposition; part (b) follows from

$$D = D', \quad S^* D^* R^{-1} = D^*, \quad S^{-1} D R = D,$$

$$D^2 R = R D^2, \quad D^2 S = S D^2.$$

The matrix (7) is the matrix of an arbitrary linear operator $A : \mathbb{C}^n \to \mathbb{C}^n$ in an orthogonal basis $f_1, \ldots, f_n$ such that $f_1, \ldots, f_{t_r}$ is a basis of

$$\text{Ker}(A - \lambda_1 I) \cdots (A - \lambda_r I), \quad 1 \leq r \leq k,$$

where

$$(x - \lambda_1) \cdots (x - \lambda_k), \quad \lambda_1 \geq \cdots \geq \lambda_k,$$

is the minimal polynomial of $A$; it proves part (a) of Lemma 2.2. Successively equating the blocks of $FS = SF'$ ordered with (2), we prove part (b).  \qed
By the *canonical part* of the matrix (6) or (7), we mean the matrix (6) or, respectively, the collection of blocks $F_{ij}$, $i \geq j$. According to Lemmas 2.1 and 2.2, the canonical part is uniquely determined by the initial matrix $A$ and does not change if $A$ is replaced by a unitarily equivalent or, respectively, similar matrix.

The algorithm for reducing a marked block matrix $A = [A_{ij}]$ to canonical form:

Let $A_{pq}$ be the first (in the ordering (2)) block of $A$ that changes under admissible transformations (3). Depending on the arrangement of the marked blocks, it is reduced by the transformations of unitary equivalence or similarity. Respectively, we reduce $A = [A_{ij}]$ to the matrix $\tilde{A} = [\tilde{A}_{ij}]$ with $\tilde{A}_{pq}$ of the form (6) or (7), and then restrict ourselves to those admissible transformations with $\tilde{A}$ that preserve the canonical part of $\tilde{A}_{pq}$. As follows from Lemmas 2.1(b) and 2.2(b), they are exactly the admissible transformations with the marked block matrix $A'$ that is obtained in the following way: The block $\tilde{A}_{pq}$ of the form (6) or (7) consists of $k$ horizontal and $k$ vertical strips; we extend this partition to the whole $p$-th horizontal and the whole $q$-th vertical strips of $\tilde{A}$. If new $k$ divisions pass through the marked block $\tilde{A}_{ij}$, we carry out $k$ perpendicular divisions such that $\tilde{A}_{ij}$ is partitioned into $k \times k$ subblocks with square diagonal blocks (they are crossed by the marking line) and repeat this for all new divisions. We additionally mark the subblocks $a_1 I, \ldots, a_{k-1} I$ of $\tilde{A}_{pq}$ if it has the form (6). The obtained marked block matrix $A'$ will be called the *derived matrix* of $A$. Clearly, $A \sim B$ implies $A' \sim B'$.

Let us consider the sequence of derived matrices

$$A^{(0)} := A, \ A', \ A'', \ldots, A^{(s)}.$$  \hspace{1cm} (8)

This sequence ends with a certain matrix $A^{(s)}$, $s \geq 0$, for which the admissible transformations do not change any of its blocks, i.e., $A^{(s)}$ is equivalent only to itself. Then $A \sim B$ implies $A^{(s)} \sim B^{(s)}$, i.e., $A^{(s)} = B^{(s)}$. Remove from $A^{(s)}$ all additional divisions into subblocks and additional marking lines that have appeared during the reduction of $A$ to $A^{(s)}$. The obtained marked block matrix will be called a *canonical matrix* or the *canonical form* of $A$ and will be denoted by $A^\infty$. We have the following

**Theorem 2.1.** Each marked block matrix $A$ is equivalent to the uniquely determined canonical matrix $A^\infty$; moreover, $A \sim B$ if and only if $A^\infty = B^\infty$. 

$\square$
We will take under consideration the null matrices $0_{0n}$, $0_{m0}$, and $0_{00}$ of size $0 \times n$, $m \times 0$, and $0 \times 0$, putting for a $p \times q$ matrix $M$

\[
M \oplus 0_{0n} = \begin{bmatrix} M & 0_{p0n} \end{bmatrix}, \quad M \oplus 0_{m0} = \begin{bmatrix} M \\ 0_{0mq} \end{bmatrix}, \quad 0_{m0} \oplus 0_{0n} = 0_{mn}.
\]

Respectively, we will consider block matrices with “empty” horizontal and/or vertical strips.

Let $A = [A_{ij}]$ and $B = [B_{ij}]$ $(1 \leq i \leq l, 1 \leq j \leq r)$ be marked block matrices with the same set of indices $(i, j)$ of the marked blocks. By the block direct sum of $A$ and $B$ we mean the marked block matrix

\[
A \uplus B := [A_{ij} \oplus B_{ij}]
\]

with the same disposition of marked blocks. If

\[
T_1 = (R_1, S_1) : A \sim C
\]

and

\[
T_2 = (R_2, S_2) : B \sim D
\]

(see (11)), then $R_1, R_2$ and, respectively, $S_1, S_2$ are block diagonal matrices with $l$ and, respectively, $r$ diagonal square blocks, and

\[
T_1 \uplus T_2 := (R_1 \uplus R_2, S_1 \uplus S_2) : A \uplus B \sim C \uplus D.
\]

A marked block matrix $A$ is said to be indecomposable if

(i) its size other than $0 \times 0$, and

(ii) $A \sim B \uplus C$ implies that $B$ or $C$ has size $0 \times 0$.

For every matrices $M_1, \ldots, M_n$, $N$, we define

\[
(M_1, \ldots, M_n) \otimes N := (M_1 \otimes N, \ldots, M_n \otimes N), \tag{9}
\]

where $M_i \otimes N$ is obtained from $M_i$ by replacing its entries $a$ with $aN$.

**Theorem 2.2.** (a) Each marked block matrix $A$ is equivalent to a matrix of the form

\[
B = (P_1 \otimes I_{m_1}) \uplus \cdots \uplus (P_t \otimes I_{m_t})
\]

\[
\sim \underbrace{P_1 \uplus \cdots \uplus P_1}_{m_1 \text{ copies}} \uplus \underbrace{P_t \uplus \cdots \uplus P_t}_{m_t \text{ copies}},
\]

\[
7
\]
where \( P_1, \ldots, P_t \) are nonequivalent indecomposable marked block matrices, uniquely determined up to equivalence (we may take \( P_1 = P_1^\infty, \ldots, P_t = P_t^\infty \)), and \( m_1, \ldots, m_t \) are uniquely determined natural numbers. Every admissible transformation \( T : B \leadsto B \) that preserves \( B \) has the form

\[
T = (1_{P_1} \otimes U_1) \cup \cdots \cup (1_{P_t} \otimes U_t),
\]

where \( 1_{P_i} = (I, I) : P_i \leadsto P_i \) is the identity transformation of \( P_i \), and \( U_i \) is a unitary \( m_i \times m_i \) matrix \( (1 \leq i \leq t) \).

(b) A marked block matrix \( A \) of size \( \neq 0 \times 0 \) is indecomposable if and only if every preserving it admissible transformation \( T : A \leadsto A \) has the form \( T = a1_A, \; a \in \mathbb{C}, \; |a| = 1 \).

(c) A canonical matrix can be reduced to an equivalent block direct sum of indecomposable canonical matrices using only admissible permutations of rows and columns.

**Proof.** (a) We may take \( A = A^\infty \). Since admissible transformations with \( A^{(i)}, \; 1 \leq i \leq s \), (see (8)) are exactly the admissible transformations with \( A \) that preserve the already reduced part of \( A^{(i)} \) (preserve \( A^{(s)} \) if \( i = s \)), the set of admissible transformations with \( A^{(s)} \) consists of all \( (R, S) : A \leadsto A \). By (3),

\[
R = R_1 \oplus \cdots \oplus R_l, \quad S = S_1 \oplus \cdots \oplus S_r,
\]

where \( l \times r \) is the number of blocks of \( A \). Since \( (R, S) : A^{(s)} \leadsto A^{(s)} \), we have

\[
R_i = U_{f(i,1)} \oplus \cdots \oplus U_{f(i,l_i)}, \quad S_j = U_{g(j,1)} \oplus \cdots \oplus U_{g(j,r_j)}, \quad (10)
\]

where

\[
 f(i, \alpha), \; g(j, \beta) \in \{1, \ldots, t\}
\]

and \( U_1, \ldots, U_t \) are arbitrary unitary matrices of fixed sizes. \( A^{(s)} \) differs from \( A \) only by additional divisions of its strips into substrips (and by additional marking lines). We transpose substrips within each strip of \( A \) to obtain a matrix \( B \sim A \) such that, for all \( (R, S) : B \sim B \), we have [10] with

\[
f(i, 1) \leq \cdots \leq f(i, l_i), \quad g(j, 1) \leq \cdots \leq g(j, r_j).
\]

Clearly, \( B \) satisfies (a).

(b)\&(c) These statements are obvious. \( \square \)
2.2 The structure of canonical matrices

In this section we divide the set of canonical $m \times n$ matrices into disjoint subsets of canonical matrices with the same “scheme” (the number of such schemes is finite for each size $m \times n$), and show how to construct all the canonical matrices with a given scheme (for matrices under unitary similarity this was made briefly in [4]).

We partition a canonical matrix into zones, which illustrate the reduction process.

Let $A = A^\infty$ be a canonical matrix. Then all its derived matrices differ from $A$ only by additional divisions and marking lines. Denote by $P_l$ ($0 \leq l < s$) the first block of $A^{(l)}$ that changes under admissible transformations (it is reduced when we construct $A^{(l+1)}$).

Let $A_{ij}^{(l)}$ be a block of $A^{(l)}$ such that either $A_{ij}^{(l)} \leq P_l$ or $l = s$. The admissible transformations with $A^{(l)}$ induce the unitary equivalence or similarity transformations with $A_{ij}^{(l)}$. Respectively, $A_{ij}^{(l)}$ has the form (6) or (7); we denote by $Z(A_{ij}^{(l)})$ its canonical part (see page 6). Defining by induction in $l$, we call $Z(A_{ij}^{(l)})$ by a zone and $l$ by its depth if either $l = 0$ or $Z(A_{ij}^{(l)})$ is not contained in a zone of depth $< l$.

For each zone $Z = Z(A_{ij}^{(l)})$, we put $Bl(Z) := A_{ij}^{(l)}$ and call $Z$ by an equivalence (similarity) zone if $Bl(Z)$ is transformed by unitary equivalence (similarity) transformations.

Clearly, every canonical matrix $A$ is partitioned into equivalence and similarity zones; for example (for a marked block matrix of the form [ ] ),
is partitioned into 10 zones, their depths are indicated on the right of (11).

Let $A$ be a canonical matrix partitioned into zones. For each similarity zone, we replace all its diagonal elements by stars. For each equivalence zone, we replace all its nonzero elements by circles, and join with a line its circles corresponding to equal elements (this line does not coincide with a marking line because the marking lines connect stars). The other elements of $A$ are zeros, we replace theirs by points. The obtained picture will be called the scheme $S(A)$ of $A$.

For example, the canonical matrix (11) has the scheme

![Scheme of Matrix A](image)

Theorem 2.3. Each canonical matrix $A = [a_{ij}]$ with a given scheme $S = [s_{ij}]$ can be constructed by successive filling of its zones by numbers starting with
the zones of greatest depth as follows: Let $Z$ be a zone of depth $d(Z)$ and let all entries in zones of depth $> d(Z)$ be replaced by numbers. Then we replace all points, circles, and stars of $Z$, respectively, by zeros, positive real numbers, and complex numbers such that the following conditions hold:

1) Let $s_{ij}$ and $s_{i+1,j+1}$ be circles in $Z$. Then $a_{ij} = a_{i+1,j+1}$ if $s_{ij}$ and $s_{i+1,j+1}$ are linked by a line, and $a_{ij} > a_{i+1,j+1}$ otherwise.

2) Let $s_{\alpha,\beta}, \ldots, s_{\alpha+k,\beta+k}$ be all stars of $Z$ that lie under a certain stair of $Z$. Then

$$a_{\alpha,\beta} = \cdots = a_{\alpha+k,\beta+k}.$$ 

If

$$s_{\alpha+k+1,\beta+k+1}, \ldots, s_{\alpha+t,\beta+t}$$

are all stars of $Z$ that lie under the next stair of $Z$, then $a_{\alpha,\beta} \preceq a_{\alpha+t,\beta+t}$; moreover, $a_{\alpha,\beta} \succeq a_{\alpha+t,\beta+t}$ whenever the columns of the block

$$[a_{ij} | \alpha \leq i \leq \alpha + k, \beta + k + 1 \leq j \leq \beta + t]$$

are linearly dependent (this block has been filled by numbers because all its entries are located in zones of depth $> d(Z)$).

This theorem gives a convenient way to present solutions of unitary matrix problems in small sizes by their sets of schemes. Thus, the list of schemes of canonical $5 \times 5$ matrices under unitary similarity was obtained by Klimenko [11].

### 2.3 Unitarily wild matrix problems

The canonical form problem for pairs of $n \times n$ matrices under simultaneous similarity (i.e., for representations of the quiver $\mathcal{Q}$) plays a special role in the theory of (non-unitary) matrix problems. It may be proved that its solution implies the classification of representations of every quiver (and even representations of every finite dimensional algebra). For this reason, the classification problem for pairs of matrices under simultaneous similarity is used as a yardstick of the complexity; Donovan and Freislich [12] (see also [2]) suggested to name a classification problem wild if it contains the problem of simultaneous similarity, and otherwise to name it tame (in accordance with the partition of animals into wild and tame ones).

The canonical form problem for an $n \times n$ matrix under unitary similarity (i.e., for unitary representations of the quiver $\mathcal{Q}$) plays the same role in the
theory of unitary matrix problems: it contains the problem of classifying unitary representations of every quiver. For example, the problem of classifying unitary representations of the quiver (5) can be regarded (by Lemma 2.2) as the problem of classifying, up to unitary similarity, matrices of the form:

$$
\begin{bmatrix}
5I & I & A_\lambda & A_\nu & A_\mu \\
0 & 4I & I & 0 & 0 \\
0 & 0 & 3I & 0 & 0 \\
0 & 0 & 0 & 2I & A_\xi \\
0 & 0 & 0 & 0 & I
\end{bmatrix}.
$$

A matrix problem is called unitarily wild (or \(*\)-wild, see [13]) if it contains the problem of classifying matrices via unitary similarity, and unitarily tame otherwise.

For each unitary problem, one has an alternative: to solve it or to prove that it is unitarily wild (and hence is hopeless in a certain sense). In this section we give some examples of such alternatives.

(i) Let us consider the problems of classifying nilpotent linear operators \(\varphi, \varphi^n = 0\), in a unitary space.

For \(n = 2\) this problem is unitarily tame; the canonical matrix of \(\varphi\) (see page 6) is

$$
\begin{bmatrix}
0 & D \\
0 & 0
\end{bmatrix},
$$

where \(D\) is of the form (6) without zero columns. Indeed, a matrix \(F = [F_{ij}]\) of the form (7) satisfies \(F^2 = 0\) only if \(k = 2, F_{11} = 0,\) and \(F_{22} = 0\); we can reduce \(F_{12}\) to the form (6).

For \(n > 2\) this problem is unitarily wild since the matrices

$$
\begin{bmatrix}
0 & I & X \\
0 & 0 & I \\
0 & 0 & 0
\end{bmatrix}
\quad \text{and} \quad
\begin{bmatrix}
0 & I & Y \\
0 & 0 & I \\
0 & 0 & 0
\end{bmatrix}
$$

are unitarily similar if and only if \(X\) and \(Y\) are unitarily similar (see also [14]).

(ii) Let us consider the problem of classifying \(m\)-tuples \((p_1, \ldots, p_m)\) of projectors \(p_i^2 = p_i\) in a unitary space.
For \( m = 1 \) this problem is unitarily time; the canonical matrix of a projector \( p = p^2 \) was obtained in [15] and [16]. Of course, it is

\[
\begin{bmatrix}
I & D \\
0 & 0
\end{bmatrix},
\]

where \( D \) is of the form (4), since a matrix \( F = [F_{ij}] \) of the form (2) satisfies \( F^2 = F \) only if \( k = 2, \ F_{11} = I, \) and \( F_{22} = 0. \)

As was proved in [16], for \( m \geq 2 \) this problem is unitarily wild even if \( p_1 \) is an orthoprojector, i.e. \( p_1 = p_1^2 = p_1^* \), (since the pairs of idempotent matrices

\[
\left( \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} X & I-X \\ X & I-X \end{bmatrix} \right)
\]

and

\[
\left( \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} Y & I-Y \\ Y & I-Y \end{bmatrix} \right)
\]

are unitarily similar if and only if \( X \) and \( Y \) are unitarily similar), or if \( p_1p_2 = p_2p_1 = 0. \)

(iii) The problems of classifying the following operators and systems of operators in unitary spaces are unitarily wild:

- Pairs of linear operators \((\varphi, \psi)\) such that
  \[
  \varphi^2 = \psi^2 = \varphi\psi = \psi\varphi = 0
  \]
  since
  
  \[
  \left( \begin{bmatrix} 0 & I \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & X \\ 0 & 0 \end{bmatrix} \right) \text{ and } \left( \begin{bmatrix} 0 & I \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & Y \\ 0 & 0 \end{bmatrix} \right)
  \]
  are unitarily similar if and only if \( X \) and \( Y \) are unitarily similar.

- Pairs of selfadjoint operators \((\varphi, \psi)\) because \( \varphi + i\psi \) is an arbitrary operator. The tame-wild dichotomy for satisfying quadratic relation pairs of selfadjoint operators in a Hilbert space was studied in [17].

- Pairs of unitary operators \((\varphi, \psi)\) since
  
  \[
  (i(\varphi + 1)(\varphi - 1)^{-1}, i(\psi + 1)(\psi - 1)^{-1})
  \]
  is a pair of selfadjoint operators (the Cayley transformation).
Partial isometries (i.e., linear operators \( \varphi \) such that \( (\varphi^* \varphi)^2 = \varphi^* \varphi \)), it was proved in [18].

(iv) The problem of classifying unitary representations of a connected quiver \( Q \) is unitarily tame if \( Q \in \{ \bullet, \bullet \to \bullet \} \) and unitarily wild otherwise.

Indeed, the classification of unitary representations of the quiver \( \bullet \to \bullet \) is given by the singular value decomposition (Lemma 2.1).

The problem of classifying unitary representations of the quiver \( \bullet \to \bullet \leftarrow \bullet \) is unitarily wild because it reduces to the unitary matrix problem for marked block matrices of the form

\[
\begin{pmatrix}
2I & 0 & 0 & I & X \\
0 & I & 0 & I & I \\
0 & 0 & 0 & I & 0
\end{pmatrix}
\quad \text{and} \quad
\begin{pmatrix}
2I & 0 & 0 & I & Y \\
0 & I & 0 & I & I \\
0 & 0 & 0 & I & 0
\end{pmatrix}
\]

are equivalent if and only if \( X \) and \( Y \) are unitarily similar. We can change the direction of an arrow in a quiver by replacing in each representation the corresponding linear mapping by the adjoint one.

(v) Let us consider the problem of classifying \( n \)-tuples \((V_1, \ldots, V_n)\) of subspaces of a unitary space \( U \) up to the following equivalence:

\[(V_1, \ldots, V_n) \sim (V'_1, \ldots, V'_n)\]

if there exists an isometry \( \varphi : U \to U \) such that

\[\varphi V_i = V'_i, \ldots, \varphi V_n = V'_n.\]

Fixing an orthogonal basis in \( U \) and (non-orthogonal) bases in \( V_1, \ldots, V_n \), we reduce it to the canonical form problem for block matrices \( A = [A_1 | \ldots | A_n] \) (the columns of \( A_i \) are the basis vectors of \( V_i \) and hence are linearly independent) up to unitary transformations of rows of \( A \) and elementary (non-unitary) transformations of columns of \( A_i \) \((i = 1, \ldots, n)\). If \( n = 1 \), then \( A = [A_1] \) reduces to \( I \oplus 0_{p_0} \); this follows from Lemma 2.1.

If \( n = 2 \), then \( A = [A_1 | A_2] \) reduces to

\[
\begin{pmatrix}
I & I & 0 & 0 & 0 \\
0 & 0 & D & 0 & 0 \\
0 & 0 & 0 & I & 0
\end{pmatrix}
\]
where $D$ is of the form $[Q]$. This block matrix reduces to a block direct sum of matrices

$$
\begin{bmatrix}
1 & \alpha \\
0 & 1
\end{bmatrix} \quad (\alpha > 0), \quad [1|1], \quad [1|0_{10}], \quad [0_{10}|1], \quad [0_{10}|0_{10}].
$$

(The problem of classifying pairs of subspaces in a complex or real vector space with scalar product given by a symmetric, or skew-symmetric, or Hermitian form was solved in [19].)

For $n = 3$ this problem is unitarily wild even if we restrict our consideration to the triples $(V_1, V_2, V_3)$ with $V_1 \perp V_2$ since

$$
\begin{bmatrix}
I & 0 & X \\
0 & I & Y \\
0 & 0 & I
\end{bmatrix}
\begin{bmatrix}
I & 0 & X' \\
0 & I & Y' \\
0 & 0 & I
\end{bmatrix}
$$

if and only if $(X, Y)$ and $(X', Y')$ determine isometric unitary representations of the quiver $\bullet \leftarrow \bullet \rightarrow \bullet$ (see page 14). An analogous statement was proved in [20] and [13]: the problem of classifying triples $(p_1, p_2, p_3)$ of orthoprojectors $p_i = p_i^2 = p_i^*$ in a unitary space is unitarily wild even if

$$
p_1 p_2 = p_2 p_1 = 0;
$$

such a triple determines, in one-to-one manner, a triple $(V_1, V_2, V_3)$ with $V_1 \perp V_2$ by means of $V_i = \text{Im } p_i$.

3 Unitary representations of a quiver

From now on, $Q$ denotes a quiver with vertices $1, \ldots, p$ and arrows $\alpha_1, \ldots, \alpha_q$. A unitary representation of dimension

$$
d = (d_1, \ldots, d_p) \in \mathbb{N}_0^p
$$

(in short, a unitary $d$ representation) will be given by assigning a matrix $A_\alpha \in \mathbb{C}^{d_j \times d_i}$ to each arrow $\alpha : i \rightarrow j$, i.e., by the sequence

$$
A = (A_{\alpha_1}, \ldots, A_{\alpha_q})
$$

(assigning to each vertex $i$ the unitary vector space $\mathbb{C}^{d_i}$ with scalar product

$$
(x, y) = \bar{x}_1 y_1 + \cdots + \bar{x}_{d_i} y_{d_i},
$$

15
we obtain a unitary representation; see page 2)

An isometry $A \sim B$ of $d$ representations $A$ and $B$ (an autometry if $A = B$) is given by a sequence

$$S = (S_1, \ldots, S_p)$$

of unitary $d_i \times d_i$ matrices $S_i$ such that

$$S_j A_\alpha = B_\alpha S_i$$

for each arrow $\alpha : i \to j$; we say also that $B$ is obtained from $A$ by admissible transformations and write $A \simeq B$. An autometry $S : A \sim A$ is scalar if $S = a 1_A$, where

$$a \in \mathbb{C}, \quad 1_A = (I_{d_1}, \ldots, I_{d_p}).$$

For two sequences of matrices

$$M = (M_1, \ldots, M_t), \quad N = (N_1, \ldots, N_t),$$

we denote

$$M \oplus N = (M_1 \oplus N_1, \ldots, M_t \oplus N_t).$$

A unitary $d$ representation $A$ of $Q$ is indecomposable if (i) $d \neq (0, \ldots, 0)$ and (ii) $A \simeq B \oplus C$ implies $B$ or $C$ has dimension $(0, \ldots, 0)$.

### 3.1 Canonical representations

Let $A$ be a unitary representation of $Q$. Using the algorithm from page 6, we reduce $A_{\alpha_1}$ to its canonical form $A_{\alpha_1}^\infty$, then restrict the set of admissible transformations with $A$ to those that preserve $A_{\alpha_1}^\infty$ (it gives certain unitary matrix problems for $A_{\alpha_2}, \ldots, A_{\alpha_q}$ with partitions them into blocks) and reduce $A_{\alpha_2}$ to its canonical form $A_{\alpha_2}^\infty$, and so on. The obtained representation

$$A^\infty = (A_{\alpha_1}^\infty, \ldots, A_{\alpha_q}^\infty)$$

(we omit the marking lines) will be called a canonical representation of the quiver $Q$; the sequence of the schemes

$$S(A^\infty) = (S(A_{\alpha_1}^\infty), \ldots, S(A_{\alpha_q}^\infty))$$

will be called the scheme of $A^\infty$.

Clearly, $A \simeq A^\infty$ and $A \simeq B$ if and only if $A^\infty = B^\infty$. 

16
Theorem 3.1. (a) Every unitary representation is isometric to a representation of the form

\[ B = (P_1 \otimes I_{m_1}) \oplus \cdots \oplus (P_t \otimes I_{m_t}) \]

\[ \simeq \underbrace{P_1 \oplus \cdots \oplus P_1}_{m_1 \text{ copies}} \oplus \cdots \oplus \underbrace{P_t \oplus \cdots \oplus P_t}_{m_t \text{ copies}} \]

(see (9)), where \( P_1, \ldots, P_t \) are nonisometric indecomposable representations, uniquely determined up to isometry, and \( m_1, \ldots, m_t \) are uniquely determined natural numbers. Every autometry \( S : B \xrightarrow{\simeq} B \) has the form

\[ S = (1_{P_1} \otimes U_1) \oplus \cdots \oplus (1_{P_t} \otimes U_t), \]

where \( U_i \) is a unitary \( m_i \times m_i \) matrix \((1 \leq i \leq t)\).

(b) A unitary representation of dimension \( \neq (0, \ldots, 0) \) is indecomposable if and only if all its autometries are scalar.

Proof. Analogously (5), the matrices of every unitary representation \( A \) of \( Q \) can be accommodated in a block diagonal matrix

\[ A = \text{diag}(A_{\alpha_q}, A_{\alpha_{q-1}}, \ldots, A_{\alpha_1}, 0, \ldots, 0) \]

with a certain set of marked blocks such that the admissible transformations with \( A \) correspond to the admissible transformations with \( M(A) \). Then \( M(A^\infty) = M(A)^\infty \) and we can apply Theorem 2.2.

3.2 The set of dimensions of indecomposable unitary representations

We will use the following notation:

- \( M_Q = [m_{ij}] \) is the \( p \times p \) matrix, in which \( m_{ij} \) is the number of arrows \( i \to j \) and \( i \leftarrow j \) of the quiver \( Q \);
- \( \text{supp}(z) \) is the full subquiver of \( Q \) with the vertex set \( \{i \mid z_i \neq 0\} \) for each \( z \in \mathbb{N}_0^p \);
- \( e_i = (0, \ldots, 1, \ldots, 0) \in \mathbb{N}_0^p \) with 1 in the \( i \)th position.
Denote by $D(Q)$ the subset of $\mathbb{N}_0^p$ consists of $e_1, \ldots, e_p$, all $e_i + e_j$ with $m_{ij} = 1$, and all nonzero $z$ with connected $\text{supp}(z) \notin \{\bullet, \bullet \rightarrow \bullet\}$ such that $zM_Q \geq z$.

In this section we prove:

**Theorem 3.2.** $D(Q)$ is the set of dimensions of indecomposable unitary representations of a quiver $Q$.

Put

$$\Delta_i(z) := \sum_j m_{ij}z_j, \quad z \in \mathbb{N}_0^p, \quad 1 \leq i \leq p.$$ 

Then

$$zM_Q = (\Delta_1(z), \ldots, \Delta_p(z)).$$

**Lemma 3.1.** $D(Q)$ satisfies the following conditions:

(i) If $z \in D(Q)$ and $\text{supp}(z) \notin \{\bullet, \bullet \rightarrow \bullet, \bullet \otimes\}$, then $zM_Q > z$.

(ii) If $z, u \in D(Q)$ and $z < u$, then there exists $i$ such that $z + e_i \leq u$ and $z + e_i \in D(Q)$.

**Proof.** (i) Let

$$z \in D(Q), \quad \text{supp}(z) \notin \{\bullet, \bullet \rightarrow \bullet, \bullet \otimes\}, \quad zM_Q = z.$$ 

Fix $i$ such that $z_i = \max\{z_1, \ldots, z_p\}$. Then $m_{ij} \neq 0$ for a certain $j \neq i$. Since

$$z_j = \Delta_j(z) \geq m_{ij}z_i \geq z_i,$$

we have

$$z_i = z_j, \quad m_{ij} = 1, \quad m_{kj}z_k = 0$$

for all $k \neq i$. Taking $z_j$ and $z_i$ instead of $z_i$ and $z_j$, we obtain $m_{ki}z_k = 0$ for all $k \neq j$. Hence $\text{supp}(z) = \bullet \rightarrow \bullet$, a contradiction.

(ii) Let $z, u \in D(Q)$ and $z < u$. If $\text{supp}(z) \neq \text{supp}(u)$, then there exists a nonzero $m_{ij}$ with

$$i \in \text{supp}(u) \setminus \text{supp}(z), \quad j \in \text{supp}(u) \cap \text{supp}(z).$$

The $z + e_i$ satisfies the requirements.
We may assume that

\[ \text{supp}(z) = \text{supp}(u) = Q. \]

Then \( Q \notin \{ \bullet, \bullet \rightarrow \bullet \} \). Fix a vertex \( l \) such that \( z_l < u_l \). We will suppose that \( \Delta_l(z) = z_l \) and \( m_{u} = 0 \) (otherwise \( z + e_l \) satisfies the requirements).

Assume first that \( z_l \leq z_j \) for some \( m_{lj} \neq 0 \). The condition \( \Delta_l(z) = z_l \) implies \( z_l = z_j \), \( m_{lj} = 1 \), and \( m_{lk} = 0 \) for all \( k \neq j \). Hence

\[ z_j = z_l < u_l \leq \Delta_l(u) = u_j. \]

Since \( Q \neq \bullet \rightarrow \bullet \), \( m_{jk} \neq 0 \) for some \( k \neq l \), and we can take \( z + e_j \).

Next, let \( z_l > z_j \) (and hence \( z + e_j \in D(Q) \)) for all nonzero \( m_{lj} \). If \( z_j = u_j \) for all \( m_{lj} \neq 0 \), then

\[ u_l \leq \Delta_l(u) = \Delta_l(z) = z_l, \]

a contradiction. Hence \( z_j < u_j \) for a certain \( m_{lj} \neq 0 \), and we can take \( z + e_j \).

**Lemma 3.2.** If \( A \) is a unitary \( d \) representation of \( Q \) and \( d \notin D(Q) \), then \( A \) is decomposable.

**Proof.** Assume to the contrary, that \( A \) is indecomposable. Then \( \text{supp}(d) \) is connected; Lemma 2.1 and \( d \notin D(Q) \) imply

\[ \text{supp}(d) \notin \{ \bullet, \bullet \rightarrow \bullet \}, \quad dM_Q \nless d, \]

that is, there exists \( l \) such that \( \Delta_l(d) < d_l \). Then \( m_{u} = 0 \) and we can assume that there are no arrows starting from \( l \) (otherwise we replace each arrow \( \alpha : l \rightarrow i \) by \( \alpha^* : i \rightarrow l \), simultaneously replacing \( A_\alpha \) by the adjoint matrix).

Let \( \alpha, \beta, \ldots, \gamma \) be all arrows stopping at \( l \); combine the corresponding them matrices of \( A \) into a single \( d_l \times \Delta_l(d) \) matrix

\[ [A_\alpha|A_\beta|\cdots|A_\gamma]. \]

The number of its rows is greater than the number of its columns; making a zero row by unitary transformations of rows, we obtain \( A \simeq B \oplus P \), where \( P \) is the zero representation of dimension \( e_l \), a contradiction. \( \square \)
Lemma 3.3. If there exists an indecomposable unitary $z$ representation and $z_i < \Delta_i(z)$ for a certain vertex $i$, then there exists an indecomposable unitary $z + e_i$ representation.

Proof. Let $A$ be an indecomposable unitary $z$ representation and $z_1 < \Delta_1(z)$. We can assume that each starting from the vertex 1 arrow is a loop (replacing each $\lambda : 1 \to j$, $j \neq 1$, by $\lambda^* : j \to 1$ and, respectively, $A_\lambda$ by $A_\lambda^*$).

1) Assume first that there is a loop $\alpha : 1 \to 1$ and define a unitary $z + e_1$ representation $H$ in which

- $H_\alpha$ is the nilpotent Jordan block of size $(z_1 + 1) \times (z_1 + 1)$,
- $H_\beta := A_\beta \oplus 0_{11}$ for each $\beta : 1 \to 1$, $\beta \neq \alpha$;
- $H_\gamma := A_\gamma \oplus 0_{10}$ for each $\gamma : j \to 1$, $j \neq 1$; and
- $H_\delta := A_\delta$ for each $\delta : j \to k$, $k \neq 1$.

The representation $H$ is indecomposable.

Indeed, let $A^-$ and $H^-$ denote the restrictions of $A$ and $H$ on the subquiver $Q^- := Q \setminus \alpha$. By Theorem 3.1(a), we may assume that

$$A^- = (P_1 \otimes I_{m_1}) \oplus \cdots \oplus (P_t \otimes I_{m_t}),$$

where $P_1, \ldots, P_t$ are nonisometric indecomposable representations of $Q^-$, $P_1$ is the zero representation of dimension $e_1$, and

$$m_1 \geq 0, \ m_2 > 0, \ldots, m_t > 0.$$ 

Clearly,

$$H^- = (P_1 \otimes I_{m_1+1}) \oplus (P_2 \otimes I_{m_2}) \oplus \cdots \oplus (P_t \otimes I_{m_t}).$$

Let

$$S = (S_1, S_2, \ldots) : H \sim H.$$ 

Since $S : H^- \sim H^-$, by Theorem 3.1(a)

$$S = (1_{P_1} \otimes U_1) \oplus \cdots \oplus (1_{P_t} \otimes U_t),$$

$$S_1 = U_1^{(d_{11})} \oplus \cdots \oplus U_t^{(d_{11})},$$ 

(12)
where \((d_{1j}, \ldots, d_{pj}) = \text{dim}(P_j)\)

and \(U_j\) is a unitary matrix \((1 \leq j \leq t)\). Since

\[ S_1 H_{\alpha} = H_{\alpha} S_1, \]

\(H_{\alpha}\) is a Jordan block and \(S_1\) is a unitary matrix, we have \(S_1 = aI, \ a \in \mathbb{C}\). The representation \(A\) is indecomposable, so that \(d_{1j} \neq 0\) and by (12) \(U_j = aI\) for all \(1 \leq j \leq t\). Hence \(S = aI_H\) and \(H\) is indecomposable by Theorem 3.1(b).

2) There remains the case \(m_{11} = 0\). Let

\[ \alpha_1 : j_1 \to 1, \ldots, \alpha_l : j_l \to 1 \]

be all the arrows stopping at 1. We denote by \(A^{-}\) the restriction of \(A\) on the subquiver

\[ Q^{-} := Q \setminus \{1; \alpha_1, \ldots, \alpha_l\}. \]

By Theorem 3.1(a), we may assume that

\[ A^{-} = (P_1 \otimes I_{m_1}) \oplus \cdots \oplus (P_t \otimes I_{m_t}), \]

where \(P_1, \ldots, P_t\) are nonisometric indecomposable unitary representations of \(Q^{-}\).

Let \((S_2, \ldots, S_p) : A^{-} \sim A^{-}\). By Theorem 3.1(a),

\[ S_i = (I_{d_{1i}} \otimes U_1) \oplus \cdots \oplus (I_{d_{ti}} \otimes U_t), \]

where \((d_{2j}, \ldots, d_{pj}) = \text{dim}P_j\). For an arbitrary unitary \(z_1 \times z_1\) matrix \(S_1\), we define \(\tilde{A}\) by means of

\[ S = (S_1, S_2, \ldots, S_p) : A \sim \tilde{A} \]

(then \(\tilde{A}^{-} = A^{-}\)). Taking into account that

\[ \tilde{A}_{\alpha_r} = S_{1}^{-1} A_{\alpha_r} S_{j_r}, \]

and partitioning the sets of columns of every \(A_{\alpha_r}\) and \(\tilde{A}_{\alpha_r}\) in the same manner as \(S_{j_r}\), we obtain

\[ B := [A_{\alpha_1}, \ldots, A_{\alpha_l}] = [B_1, \ldots, B_m] \]
and
\[ \tilde{B} := [\tilde{A}_{\alpha_1} | \cdots | \tilde{A}_{\alpha_l}] = [\tilde{B}_1 | \cdots | \tilde{B}_m], \]
where
\[ m = \sum_{\tau=1}^{l} (d_{j_{\tau 1}} + \cdots + d_{j_{\tau t}}) \]
and
\[ \tilde{B}_i = S_1^{-1} B_i U_{f(i)} \]
for a certain \( f(i) \in \{1, \ldots, t\} \).

Let \( z_1 \times u_i \) be the size of \( B_i \) and put
\[ r_i = \text{rank}[B_1 | \cdots | B_{i-1}|B_{i+1} | \cdots | B_m]. \]

\( B \) is a \( z_1 \times \Delta_1(z) \) matrix and \( z_1 < \Delta_1(z) \), so \( z_1 - r_i < u_i \) for a certain \( i \). Since \( S_1 \) and \( U_{f(i)} \) are arbitrary unitary matrices, by Lemma 2.1(a) there exists \( S \) such that
\[ \tilde{B} = \begin{bmatrix} C_1 & \cdots & C_{i-1} & C_i & C_{i+1} & \cdots & C_m \end{bmatrix}, \]
where the rows of
\[ [C_1 | \cdots | C_{i-1} | C_{i+1} | \cdots | C_m] \]
are linearly independent and \( D \) is a \( (z_1 - r_i) \times u_i \) matrix of the form
\[ \text{diag}(a_1, \ldots, a_n) \oplus 0_{kh} \]
with real \( a_1 \geq \cdots \geq a_n > 0 \). Since \( \tilde{A} \) is indecomposable and \( z_1 - r_i < u_i \), we have \( k = 0 \) and \( h > 0 \).

Let \( a_{n+1} \) be a real number such that \( a_n > a_{n+1} > 0 \). The replacement \( D \) by
\[ D' = \text{diag}(a_1, \ldots, a_n, a_{n+1}) \oplus 0_{0,h-1} \]
changes \( \tilde{B} \) to a new matrix \( \tilde{B}' \) and \( \tilde{A} \) to a new representation \( H \) of dimension \( z + e_1 \).

Let \( R : H \xrightarrow{\sim} H \). Since \( H \) and \( A \) coincide on \( Q^- \) and
\[ (R_2, \ldots, R_p) : A^- \xrightarrow{\sim} A^- , \]
by Theorem 3.1(a) the matrices \( R_2, \ldots, R_p \) have the form
\[ R_j = (I_{d_{j_1}} \otimes V_1) \oplus \cdots \oplus (I_{d_{j_r}} \otimes V_r) \]
with unitary $V_1, \ldots, V_\tau$. By

$$R_1^{-1} \tilde{B}'(R_{j_1} \oplus \cdots \oplus R_{j_\ell}) = \tilde{B}' ,$$

$R_1$ has the form $R_{11} \oplus R_{12}$, where

$$R_{12}^{-1}D'V_{f(i)} = D'.$$

Lemma 2.1 implies

$$R_{12} = R_{13} \oplus [c].$$

Putting

$$\tilde{R}_1 = R_{11} \oplus R_{13}, \quad \tilde{R}_j = R_j \ (j > 1),$$

we have $\tilde{R} : \tilde{A} \sim \tilde{A}$. By Theorem 3.1(b),

$$\tilde{R}_j = aI, \quad 1 \leq j \leq p,$$

for some $a \in \mathbb{C}$, so

$$V_j = aI, \quad 1 \leq j \leq \tau.$$ 

In particular, $V_{f(i)} = aI$ and, since

$$R_{12}^{-1}D'V_{f(i)} = D',$$

c = a and $R_1 = aI$. Therefore $R = a1_H$ and $H$ is indecomposable by Theorem 3.1(b). \qed

**Proof of Theorem 3.2.** Let $U(Q)$ denote the set of dimensions of indecomposable unitary representations of $Q$. Lemma 3.2 implies $U(Q) \subset D(Q)$.

Let $u \in D(Q)$. Then $u_i \neq 0$ for a certain $i$. Using Lemma 3.1(ii), we select a sequence

$$u_1 := e_i, \ u_2, \ldots, u_t := u$$

in $D(Q)$ such that

$$u_2 - u_1, \ldots, u_t - u_{t-1} \in \{e_1, \ldots, e_p\}.$$ 

By Lemma 3.3,

$$\{u_1, \ldots, u_t\} \subset U(Q), \quad D(Q) \subset U(Q).$$ \qed
3.3 The number of parameters in an indecomposable unitary representation

By the number of real (complex) parameters of a unitary representation $A$ we mean the number of circles (stars) in the scheme $S(A^\infty)$. Recall that to circles correspond positive real numbers in $A^\infty$, and to stars correspond complex numbers; the other entries in $A^\infty$ are zeros.

Kac [7, Theorem C] proved that the maximal number of parameters in an indecomposable (non-unitary) representation of dimension $d$ over an algebraically closed field is $1 - \varphi_Q(d)$, where

$$\varphi_Q(x) = x_1^2 + \cdots + x_p^2 - \sum_{i,j=1}^{p} m_{ij}x_i x_j$$

is a $\mathbb{Z}$-bilinear form called the Tits form of the quiver $Q$, and $m_{ij}$ is the number of arrows $i \to j$ and $i \leftarrow j$.

We say that a zone (see page 9) is in general position if all its diagonal entries are distinct and, if it is an equivalence zone, nonzero. A unitary representation $A$ is said to be in general position if all zones in $A^\infty$ are in general position.

**Theorem 3.3.** (a) For every $d \in D(Q)$ (see page 13) there exists an indecomposable canonical unitary $d$ representation of general position, its scheme is uniquely determined by $d$.

(b) An indecomposable unitary $d$ representation $A$ has $\sum d_i - 1$ real parameters and at most

$$1 - \varphi_Q(d) + \frac{1}{2} \sum d_i(d_i - 1)$$

complex parameters; this number is reached if and only if $A$ is in general position.

**Proof.** We consider the set of zones of a canonical unitary representation $A^\infty = (A^\infty_{a_1}, \ldots, A^\infty_{a_q})$ as linearly ordered:

$$Z_1 < Z_2 \text{ if } i_1 < i_2; \text{ or } i_1 = i_2 \text{ and } l_1 < l_2;$$

$$\text{or } i_1 = i_2, \text{ } l_1 = l_2 \text{ and } \text{Bl}(Z_1) < \text{Bl}(Z_2) \tag{13}$$

(see [2] and Section 2.2); where $Z_k$ ($k = 1, 2$) is a zone of depth $l_k$ in $A^\infty_{a_{d_k}}$. 

24
(a) Let \( d \in D(Q) \). By Theorem 3.2, there exists an indecomposable unitary \( d \) representation \( A \). Let \( A \) be not in general position, and let \( Z \) be the first (in the sense of (13)) zone of \( A^\infty \) that is not in general position. Changing diagonal entries of \( Z \), we transform it into a zone \( \tilde{Z} \) of general position and \( A^\infty \) into a new representation \( \tilde{A} \). This exchange narrows down the set of admissible transformations that preserve all zones \( \leq Z \), and, by Theorem 3.1(b), \( A^\infty \) has only scalar autometries (as an indecomposable representation), therefore, \( \tilde{A} \) has only scalar autometries and is indecomposable too.

If \( \tilde{A} \) is not in general position, we repeat this process for it, and so on, until we obtain an indecomposable \( d \) representation \( B \) of general position. Its scheme is uniquely determined since, for each zone \( Z \) of \( B \), the set of admissible transformations that preserve all zones \( \leq Z \), and hence the matrix problem for the remaining part of \( B \) does not depend on diagonal entries of \( Z \) such that it is in general position.

(b) Let \( A \) be an indecomposable canonical \( d \) representation, and \( Z \) be its zone or the symbol \( \infty \). Denote by \( J(Z) \) the set of all isometries of the form \( S : A \xrightarrow{\sim} \tilde{A} \) that preserve all zones \( < Z \) (all zones if \( Z = \infty \)). As follows from the algorithms from pages 6 and 16, \( J(Z) \) consists of all sequences of the form \( S = (S_1, \ldots, S_p) \), where

\[
S_i = U_{\sigma(i_1)} \oplus U_{\sigma(i_2)} \oplus \cdots \oplus U_{\sigma(i_t)};
\]

\( \sigma : \{(i,j) \mid 1 \leq i \leq p, 1 \leq j \leq t_i \} \to \{1, \ldots, t\} \)

is a fixed surjection, and \( U_1, \ldots, U_t \) are arbitrary unitary matrices of fixed sizes \( m_1 \times m_1, \ldots, m_t \times m_t \) (we will write \( S = S(U_1, \ldots, U_t) \)).

Put

\[
\Delta_1(Z) = m_1 + \cdots + m_t, \quad \Delta_2(Z) = m_1^2 + \cdots + m_t^2.
\]

Let \( Z \neq \infty \) and \( Z' \) be the first zone after \( Z \) (\( Z' = \infty \) if \( Z \) is the last zone of \( A \)). We will prove that

\[
\Delta_1(Z) - \Delta_1(Z') = n^*(Z), \tag{14}
\]

\[
\Delta_2(Z) - \Delta_2(Z') \leq 2n(Z) - n^*(Z) - 2n^*(Z), \tag{15}
\]

and that the equality in (15) holds if and only if \( Z \) is a zone of general position; where \( n(Z) \) is the number of entries in \( Z \), and \( n^*(Z) \) (resp., \( n^*(Z) \)) is the number of circles (resp., stars) that correspond to the diagonal entries of \( Z \).
As follows from the algorithms from pages 6 and 16, the block $\text{Bl}(Z)$ is reduced by transformations

$$\text{Bl}(Z) \leftrightarrow U_i^{-1}\text{Bl}(Z)U_j,$$

(16)

where

$$S = S(U_1, \ldots, U_t) \in J(Z)$$

and $i$ and $j$ are determined by $Z$; moreover, this $S$ is contained in $J(Z')$ if and only if (16) preserves $Z$.

(i) Let $i \neq j$, say, $i = 1$ and $j = 2$. Then, by Lemma 2.1

$$Z = \text{Bl}(Z) = a_1I_{r_1} \oplus \cdots \oplus a_{k-1}I_{r_{k-1}} \oplus 0_{xy}, \quad r_\alpha \geq 1,$$

$x \geq 0$, and $y \geq 0$. The transformation (16) preserves $Z$ if and only if

$$U_1 = V_1 \oplus \cdots \oplus V_k \quad \text{and} \quad U_2 = V_1 \oplus \cdots \oplus V_{k-1} \oplus V_{k+1},$$

(17)

where $V_1, \ldots, V_{k+1}$ are unitary matrices of sizes

$$r_1 \times r_1, \ldots, r_{k-1} \times r_{k-1}, \quad x \times x, \quad y \times y.$$

Hence, $J(Z')$ consists of all $S \in J(Z)$ with $U_1$ and $U_2$ of the form (17), that is,

$$S = S(V_1 \ldots V_{k+1}, U_3 \ldots U_t).$$

Therefore,

$$\Delta_1(Z') = r_1 + \cdots + r_{k-1} + x + y + m_3 + \cdots + m_t,$$

$$\Delta_2(Z') = r_1^2 + \cdots + r_{k-1}^2 + x^2 + y^2 + m_3^2 + \cdots + m_t^2.$$

By (16), $\text{Bl}(Z)$ has size $m_1 \times m_2$,

$$m_1 = r_1 + \cdots + r_{k-1} + x, \quad m_2 = r_1 + \cdots + r_{k-1} + y,$$

so

$$n(Z) = m_1m_2, \quad n^*(Z) = r_1 + \cdots + r_{k-1}, \quad n^*(Z) = 0.$$

We have

$$\Delta_1(Z) - \Delta_1(Z') = r_1 + \cdots + r_{k-1} = n^*(Z)$$
and

\[
\Delta_2(Z) - \Delta_2(Z') = (r_1 + \cdots + r_{k-1} + x)^2 \\
+ (r_1 + \cdots + r_{k-1} + y)^2 - r_1^2 - \cdots - r_{k-1}^2 - x^2 - y^2 \\
= [(r_1 + \cdots + r_{k-1} + x) - (r_1 + \cdots + r_{k-1} + y)]^2 \\
+ 2(r_1 + \cdots + r_{k-1} + x)(r_1 + \cdots + r_{k-1} + y) \\
- r_1^2 - \cdots - r_{k-1}^2 - x^2 - y^2 \\
= (x - y)^2 + 2n(Z) - r_1^2 - \cdots - r_{k-1}^2 - x^2 - y^2 \\
= -2xy + 2n(Z) - r_1^2 - \cdots - r_{k-1}^2 \\
\leq 2n(Z) - r_1 - \cdots - r_{k-1} = 2n(Z) - n^*(Z).
\]

Moreover, we have the equality if and only if

\[
r_1 = \cdots = r_{k-1} = 1, \quad xy = 0,
\]
i.e, \(Z\) is in general position.

(ii) Let \(i = j\), say, \(i = j = 1\). Then, by Lemma 2.2, \(\text{Bl}(Z) = [F_{\alpha\beta}]\), where

\[
F_{\alpha\beta} = 0 \quad \text{if} \ \alpha > \beta, \ \text{and} \\
F_{\alpha\alpha} = \lambda_\alpha I_{r_\alpha}, \quad r_\alpha \geq 1, \quad r_1 + \cdots + r_k = m_1.
\]

The transformation (16) preserves

\[
Z = \{F_{\alpha\beta} \mid \alpha \leq \beta\}
\]

if and only if

\[
U_1 = V_1 \oplus \cdots \oplus V_k,
\]

where \(V_1, \ldots, V_k\) are unitary matrices of sizes

\[
r_1 \times r_1, \ldots, r_k \times r_k.
\]

Hence, \(J(Z')\) consists of all \(S \in J(Z)\) with

\[
U_1 = V_1 \oplus \cdots \oplus V_k,
\]

that is,

\[
S = S(V_1, \ldots, V_k, U_2, \ldots, U_t).
\]

So

\[
\Delta_1(Z) - \Delta_1(Z') = m_1 - r_1 - \cdots - r_k = 0 = n^*(Z)
\]
and
\[ \Delta_2(Z) - \Delta_2(Z') = (r_1 + \cdots + r_k)^2 - r_1^2 - \cdots - r_k^2 \]
\[ = 2 \sum_{\alpha \leq \beta} r_\alpha r_\beta - 2(r_1^2 + \cdots + r_k^2) \]
\[ = 2n(Z) - 2(r_1^2 + \cdots + r_k^2) \]
\[ \leq 2n(Z) - 2(r_1 + \cdots + r_k) \]
\[ = 2n(Z) - 2n^*(Z). \]

Moreover, we have the equality if and only if
\[ r_1 = \cdots = r_k = 1, \]
that is, \( Z \) is in general position.

Hence, the relations (14) and (15) hold.

Let \( Z_1 < \cdots < Z_r \) be all zones of \( A \) ordered by (13), and let
\[ \dim A = (d_1, \ldots, d_p). \]

Then \( Z_i' = Z_{i+1} \) for \( i < r \), and \( Z_r' = \infty \). Since \( J(Z_1) \) consists of all sequences \( S = (S_1, \ldots, S_p) \) of unitary \( d_1 \times d_1, \ldots, d_p \times d_p \) matrices,
\[ \Delta_1(Z_1) = d_1 + \cdots + d_p, \quad \Delta_2(Z_1) = d_1^2 + \cdots + d_p^2. \]

Since \( A \) is indecomposable, by Theorem 3.1(b) \( J(\infty) \) consists of all sequences
\[ S = \lambda(I_{d_1}, \ldots, I_{d_p}), \quad \lambda \in \mathbb{C}, \quad |\lambda| = 1, \]
so
\[ S = S([\lambda]), \quad \Delta_1(\infty) = \Delta_2(\infty) = 1. \]

By (13),
\[ d_1 + \cdots + d_p - 1 = \Delta_1(Z_1) - \Delta_1(\infty) \]
\[ = \sum_{i=1}^{r} (\Delta_1(Z_i) - \Delta_1(Z_i')) = \sum_{i=1}^{r} n^*(Z_i) \]
is the number of circles in \( S(A^\infty) \), that is, the number of real parameters in \( A \).
By (15),

\[
d_1^2 + \ldots + d_p^2 - 1 = \Delta_2(Z_1) - \Delta_2(\infty)
\]

\[
= \sum_{i=1}^{r} (\Delta_2(Z_i) - \Delta_2(Z'_i))
\]

\[
\leq 2 \sum_{i=1}^{r} n(Z_i) - \sum_{i=1}^{r} n^*(Z_i) - 2 \sum_{i=1}^{r} n^*(Z_i).
\]

But \(\sum_{i=1}^{r} n(Z_i)\) is the number of entries in \(A_{\alpha_1}, \ldots, A_{\alpha_q}\), hence, it is equal to

\[
\sum_{i,j=1}^{p} m_{ij}d_id_j,
\]

where \(m_{ij}\) is the number of arrows \(i \to j\) and \(i \leftarrow j\);

\[
n^*(A) := \sum_{i=1}^{r} n^*(Z_i)
\]

is the number of complex parameters in \(A\). Therefore,

\[
n^*(A) \leq \sum_{i,j=1}^{p} m_{ij}d_id_j - \frac{1}{2} (\sum_{i=1}^{r} d_i^2 - 1) - \frac{1}{2} (\sum_{i=1}^{r} d_i - 1)
\]

\[
= 1 - [\sum_{i=1}^{r} d_i^2 - \sum_{i,j=1}^{p} m_{ij}d_id_j] + \frac{1}{2} (\sum_{i=1}^{r} d_i^2 - d_i)
\]

\[
= 1 - \varphi_Q(d) + \frac{1}{2} \sum_{i=1}^{r} d_i(d_i - 1).
\]

We have the equality if and only if all \(Z_i\) are in general position, i.e., \(A\) is in general position.

The proof implies

**Corollary 3.1.** (a) Let \(d \in D(Q)\) and \(m = \max\{d_1, \ldots, d_p\}\). Then there exists an indecomposable canonical \(d\) representation of general position with entries in \(\{0, 1, \ldots, m\}\).

(b) A decomposable unitary \(d\) representation has less than \(\sum d_i - 1\) real parameters and less than

\[
1 - \varphi_Q(d) + \frac{1}{2} \sum_{i=1}^{r} d_i(d_i - 1)
\]

complex parameters.
Proof. (a) This statement follows from Theorems 3.3(a) and 2.3.

(b) This statement is proved as Theorem 3.3(b), but, in the last two paragraphs of its proof, we must use $\Delta_1(\infty) > 1$ and $\Delta_2(\infty) > 1$ instead of

$$\Delta_1(\infty) = \Delta_2(\infty) = 1$$

since $J(\infty)$ contains a non-scalar authometry in the case of a decomposable representation $A$. $lacksquare$

4 Euclidean representations of a quiver

Let $Q$ be a quiver with vertices $1, \ldots, p$ and arrows $\alpha_1, \ldots, \alpha_q$. A Euclidean representation $A$ of dimension

$$d = (d_1, \ldots, d_p) \in \mathbb{N}_0^p$$

will be given by assigning a matrix $A_\alpha \in \mathbb{R}^{d_j \times d_i}$ to each arrow $\alpha : i \to j$; i.e.,

by the sequence

$$A = (A_{\alpha_1}, \ldots, A_{\alpha_q}).$$

An $\mathbb{R}$-isometry $A \sim B$ of Euclidean representations $A$ and $B$ will be given by a sequence $S = (S_1, \ldots, S_p)$ of real orthogonal matrices such that $S_i A_\alpha = B_\alpha S_i$ for each arrow $\alpha : i \to j$ (analogously, $R : A \sim C$ $B$ denotes an isometry in the sense of Section 3). A Euclidean $d$ representation $A$ is said to be $\mathbb{R}$-indecomposable if (i) $d \neq (0, \ldots, 0)$ and (ii) $A \sim B \oplus C$ implies that $B$ or $C$ has dimension $(0, \ldots, 0)$.

For a sequence of complex matrices

$$M = (M_1, \ldots, M_n),$$

we define the conjugate sequence

$$\bar{M} = (\bar{M}_1, \ldots, \bar{M}_n),$$

the transposed sequence

$$M^T = (M_1^T, \ldots, M_n^T),$$

and the adjoint sequence

$$M^* = \bar{M}^T.$$

Clearly, the Euclidean representations are the selfconjugate unitary representations.
4.1 A reduction to unitary representations

We give a standard reduction of the problem of classifying Euclidean representations to the problem of classifying unitary representations.

Let $\text{ind}(Q)$ and $\text{ind}_\mathbb{R}(Q)$ denote complete systems of nonisometric indecomposable unitary representations and non-$\mathbb{R}$-isometric $\mathbb{R}$-indecomposable Euclidean representations respectively. Let us replace each representation in $\text{ind}(Q)$ that is isometric to a Euclidean representation by a Euclidean one, and denote the set of such by $\text{ind}_0(Q)$ (if $A \in \text{ind}(Q)$ and $S : A \cong C \tilde{A}$, then $A$ is isometric to a Euclidean representation if and only if $S^T = S$; see Theorem 4.2). Denote by $\text{ind}_1(Q)$ the set consisting of all representations from $\text{ind}(Q)$ that are isometric to their conjugates, but not to a selfconjugate, together with one representation from each pair $\{A, B\} \subset \text{ind}(Q)$ such that $A \not\cong C \tilde{A} \cong B$.

For a unitary $d$ representation

$$A = (A_\alpha_1, \ldots, A_\alpha_q),$$

we define the Euclidean $2d$ representation

$$A^\mathbb{R} = (A^\mathbb{R}_\alpha_1, \ldots, A^\mathbb{R}_\alpha_q),$$

where $A^\mathbb{R}_\alpha$ is obtained from $A_\alpha$ by replacing each entry $a + bi$ ($a, b \in \mathbb{R}$) by the block

$$\begin{pmatrix} a & b \\ -b & a \end{pmatrix}.$$

Since

$$U^{-1} \begin{pmatrix} a & b \\ -b & a \end{pmatrix} U = \begin{pmatrix} a + bi & 0 \\ 0 & a - bi \end{pmatrix}$$

with the unitary

$$U = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & -1 \\ i & i \end{bmatrix},$$

we have

$$A^\mathbb{R} \cong C A \oplus \tilde{A}. \quad (18)$$
Theorem 4.1. (a) Let $A$ and $B$ be Euclidean representations of a quiver $Q$. Then $A \simeq_{\mathbb{R}} B$ if and only if $A \simeq_{\mathbb{C}} B$.

(b) Every Euclidean representation is $\mathbb{R}$-isometric to a direct sum of indecomposable Euclidean representations, uniquely determined up to $\mathbb{R}$-isometry of summands. Moreover,

$$\text{ind}_{\mathbb{R}}(Q) = \text{ind}_{0}(Q) \cup \{A^\mathbb{R} \mid A \in \text{ind}_1(Q)\}. \quad (19)$$

(c) The set of dimensions of $\mathbb{R}$-indecomposable Euclidean representations of $Q$ coincides with the set of dimensions of indecomposable unitary representations and is equal to $D(Q)$ (see page 18).

A homomorphism ($\mathbb{R}$-homomorphism) $S : A \to B$ of representations $A$ and $B$ of $Q$ is a sequence of complex (real) matrices $S = (S_1, \ldots, S_p)$ such that $S_jA_{\alpha} = B_{\alpha}S_i$ for each arrow $\alpha : i \to j$. Clearly, an isomorphism $S$ is an isometry if and only if $S^* = S^{-1}$.

Lemma 4.1. The following properties are equivalent for a unitary (Euclidean) representation $A$:

(i) $A$ is decomposable ($\mathbb{R}$-decomposable).

(ii) There exists an endomorphism ($\mathbb{R}$-endomorphism) $F : A \to A$ such that $F = F^* = F^2 \notin \{0_A, 1_A\}$.

(iii) There exists a nonscalar selfadjoint endomorphism ($\mathbb{R}$-endomorphism) $S = S^* : A \to A$.

Proof. (i)⇒(ii) Let $S : A \sim B \oplus C$ be an isometry of unitary representations ($\mathbb{R}$-isometry of Euclidean representations) and $B \neq 0 \neq C$. Then

$$F := S^{-1}(1_B \oplus 0_C)S : A \to A$$

satisfies (ii).

(ii)⇒(iii) Put $S := F$.

(iii)⇒(i) Since every $S_i$ in $S$ is a Hermitian (resp., real symmetric) matrix, there exists a unitary (real orthogonal) matrix $U_i$ such that

$$R_i := U_iS_iU_i^{-1} = \text{diag}(a_{i1}, \ldots, a_{it_i}).$$
where $a_{ij} \in \mathbb{R}$ and
\[ a_{i1} \geq \cdots \geq a_{it}. \]
Define the unitary (Euclidean) representation $B$ by means of the isometry
\[ U := (U_1, \ldots, U_p) : A \sim B. \]
Then
\[ R := USU^{-1} : B \sim B \]
is an isometry and
\[ R = a_1\mathbb{I}_1 \oplus \cdots \oplus a_t\mathbb{I}_t, \]
where
\[ a_1 > \cdots > a_t, \quad \mathbb{I}_i = (I_{n_{i1}}, \ldots, I_{n_{ip}}), \quad n_{ij} \geq 0. \]
Clearly,
\[ B = B_1 \oplus \cdots \oplus B_t, \]
where
\[ \dim(B_i) = (n_{i1}, \ldots, n_{ip}). \]

Proof of Theorem 4.1. 1) We first prove the statement (a) for an $\mathbb{R}$-indecomposable Euclidean representation $A$. Let
\[ S = \Phi + i\Psi : A \sim B, \]
where $\Phi$ and $\Psi$ are real matrices and $B$ is a Euclidean representation. Then $\Phi$ and $\Psi$ are $\mathbb{R}$-endomorphisms $A \to B$. Since
\[ 1_A = S^*S = (\Phi^T - i\Psi^T)(\Phi + i\Psi) = (\Phi^T\Phi + \Psi^T\Psi) + i(\Phi^T\Psi - \Psi^T\Phi), \]
we have
\[ \Phi^T\Phi + \Psi^T\Psi = 1_A. \]
By Lemma 4.1, the selfadjoint $\mathbb{R}$-endomorphisms $\Phi^T\Phi$ and $\Psi^T\Psi$ are scalar, that is,
\[ \Phi^T\Phi = \lambda 1_A, \quad \Psi^T\Psi = \mu 1_A, \quad \lambda + \mu = 1. \]
Obviously, $\lambda$ and $\mu$ are non-negative real numbers. For definiteness, $\lambda > 0$, then $\lambda^{-\frac{3}{2}}\Phi: A \sim_{\mathbb{R}} B$.

2) Let $A$ be an $\mathbb{R}$-indecomposable Euclidean representation that is decomposable as a unitary representation. We prove that

$$A \simeq_{\mathbb{R}} B^\mathbb{R} \simeq_{\mathbb{C}} B \oplus B,$$

where $B$ is an indecomposable unitary representation that is not isometric to a Euclidean representation.

Indeed, by Lemma 4.1 there exists an endomorphism $F: A \to A$ such that

$$F = F^* = F^2 \notin \{0_A, 1_A\}.$$ 

Let $F = \Phi + i\Psi$, where $\Phi$ and $\Psi$ are sequences of real matrices. Since

$$F = F^* = \Phi^T - i\Psi^T,$$

it follows that $\Phi = \Phi^T$ and $\Psi = -\Psi^T$. By Lemma 4.1 the endomorphism $\Phi$ is scalar, i.e., $\Phi = \lambda 1_A$, $\lambda \in \mathbb{R}$. If $\lambda = 0$, then

$$i\Psi = F = F^2 = -\Psi^2$$

and $\Psi = 0_A$, a contradiction.

Hence $\lambda \neq 0$. Since

$$F = F^2 = (\lambda 1_A + i\Psi)^2 = (\lambda^2 1_A - \Psi^2) + 2\lambda i\Psi,$$

we have

$$\lambda^2 1_A - \Psi^2 = \lambda 1_A, \quad 2\lambda\Psi = \Psi.$$

The condition $F \neq 1_A$ implies

$$\Psi \neq 0_A, \quad \lambda = \frac{1}{2}, \quad \Psi^2 = -\frac{1}{4}1_A.$$

By [21, Sect. 4.4, Exercise 25], every nonsingular skew-symmetric real matrix is real orthogonally similar to a direct sum of matrices of the form

$$\begin{bmatrix} 0 & a \\ -a & 0 \end{bmatrix}, \quad a > 0.$$

Since

$$\Psi^T = -\Psi, \quad \Psi^2 = -\frac{1}{4}1_A,$$

34
there exists a sequence $S$ of real orthogonal matrices such that

$$S\Psi S^{-1} = \frac{1}{2} \mathbb{I} \otimes \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$$

(see (9)), where $\mathbb{I} = (I, \ldots, I)$. Put

$$G := SFS^{-1} = \frac{1}{2} \mathbb{I} \otimes \begin{bmatrix} 1 & i \\ -i & 1 \end{bmatrix}.$$

Define the Euclidean representation $C$ by means of $S$: $A \sim \mathbb{R} \to \mathbb{R}^C$. Then

$$G : C \to C$$

is an $\mathbb{R}$-endomorphism. It follows from the form of $G$ and the definition of homomorphisms, that $C = B^\mathbb{R}$ for a certain $B$.

If $B$ is a decomposable unitary representation, say, $B \simeq \mathbb{C} X \oplus Y$, then by (18)

$$A \simeq \mathbb{R} B \simeq \mathbb{C} B \oplus \bar{B} \simeq \mathbb{C} X \oplus Y \oplus \bar{X} \oplus \bar{Y} \simeq \mathbb{C} X^\mathbb{R} \oplus Y^\mathbb{R},$$

by 1) $A \simeq \mathbb{R} X^\mathbb{R} \oplus Y^\mathbb{R}$, a contradiction.

If $B$ is isometric to a Euclidean representation, say, $B \simeq \mathbb{C} D = \bar{D}$, then

$$A \simeq \mathbb{R} B \simeq \mathbb{C} B \oplus \bar{B} \simeq \mathbb{C} D \oplus D,$$

by 1) $A \simeq \mathbb{R} D \oplus D$, a contradiction.

(a)–(b). Let $A$ and $B$ be Euclidean representations, $A \simeq \mathbb{R} B$,

$$A \simeq \mathbb{R} A_1 \oplus \cdots \oplus A_l, \quad B \simeq \mathbb{R} B_1 \oplus \cdots \oplus B_r,$$

where $A_i$ and $B_j$ are $\mathbb{R}$-indecomposable. From 2) and Theorem 3.1(a), $l = r$ and, after a permutation of summands, $A_i \simeq \mathbb{C} B_i$. By 1), $A_i \simeq \mathbb{R} B_i$. The equality (19) is obvious.

(c). By Corollary 3.1(a), there exists an $\mathbb{R}$-indecomposable Euclidean representation (with entries in $\mathbb{N}_0$) of dimension $z$ for every $z \in D(\mathbb{Q})$. Conversely, let $A$ be an $\mathbb{R}$-indecomposable Euclidean representation. If $A$ is indecomposable as a unitary representation, then by Theorem 3.2 $\dim(A) \in D(\mathbb{Q})$. Otherwise by 2) $A \simeq \mathbb{C} B \oplus \bar{B}$, where $B$ is an indecomposable unitary representation, i.e., $d := \dim(B) \in D(\mathbb{Q})$. Since $B$ is not isometric to a Euclidean representation,

$$\text{supp}(d) \notin \{\bullet, \bullet \to \bullet\}.$$
Applying twice the definition of $D(Q)$ (see page 3.2), we have
\[ dM_Q \geq d, \quad 2dM_Q \geq 2d, \quad \dim(A) = 2d \in D(Q). \]

\[ \square \]

4.2 Unitary representations that are isometric to Euclidean representations

Theorem 4.1(b) reduces the problem of classifying Euclidean representations of a quiver $Q$ to the following two problems:

- classify unitary representations of $Q$ (i.e., construct the set $\text{ind}(Q)$);
- bring to light for each $A \in \text{ind}(Q)$ whether it is isometric to a Euclidean representation and to construct that representation.

In this section we consider the second problem.

Lemma 4.2. (a) If $S$ is a symmetric unitary matrix, then there exists a unitary matrix $U$ such that $S = U^T U$.

(b) If $S$ is a skew-symmetric unitary matrix, then there exists a unitary matrix $U$ such that
\[ S = U^T \left( \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \oplus \cdots \oplus \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \right) U. \]

Proof. Analogous statement for a non-unitary matrix $S$ is given in [21, Sect. 4.4, Corollary 4.4.4 and Exercise 26]. The condition of unitarity makes its proof much more easy. We give it sketchily since an explicit form of $U$ is needed for the applications of the next theorem.

Given a symmetric (skew-symmetric) unitary matrix $S_n$ with rows $s_1, \ldots, s_n$. If
\[ s_1 \neq e_1 := (1, 0, \ldots, 0), \]
we take a unitary matrix $U_n$ with rows $u_1, \ldots, u_n$ such that
\[ u_1 = \alpha(e_1 + s_1), \quad \alpha \in \mathbb{C}, \]
(resp., $\mathbb{C}u_1 + \mathbb{C}u_2 = \mathbb{C}e_1 + \mathbb{C}s_1$). Then
\[ \bar{u}_1 S_n = \alpha(e_1 + s_1)S_n = \alpha(e_1 S_n + s_1 S_n) \]
\[ = \alpha(s_1 + e_1) = u_1 = e_1 U_n, \]

36
hence
\[(U_n^{-1})^T S_n U_n^{-1} = \bar{U}_n S_n U_n^{-1} = [1] \oplus S_{n-1}\]
(resp., then
\[\bar{U}_n S_n U_n^{-1} = \begin{bmatrix} 0 & \beta \\ -\beta & 0 \end{bmatrix} \oplus S_{n-2},\]
\[|\beta| = 1;\] replacing \(u_2\) by \(\beta u_2\), we make \(\beta = 1\)). If \(s_1 = e_1\), we have
\[S_n = [1] \oplus S_{n-1}, \quad U_n := I_n.\]
We repeat this procedure until we obtain the required
\[U := U_n(I_1 \oplus U_{n-1})(I_2 \oplus U_{n-2}) \cdots (I_{n-1} \oplus U_1)\]
(resp., \(U := U_n(I_2 \oplus U_{n-2}) \cdots\)). \(\square\)

**Theorem 4.2.** (a) Let \(A\) be a unitary representation and \(A \not\cong C \bar{A}\). Then \(A\) is not isometric to a Euclidean representation.

(b) Let \(A\) be an indecomposable unitary representation and \(S : A \sim C \bar{A}\).

(i) If \(S = S^T\), then \(A\) is isometric to a Euclidean representation \(B\) given by \(U : A \sim C B\), where \(U_1, \ldots, U_p\) are arbitrary unitary matrices such that \(U_i^T U_i = S_i\) (they exist by Lemma 4.2(a)).

(ii) If \(S \neq S^T\), then \(S = -S^T\) and \(A\) is not isometric to a Euclidean representation but is isometric to a unitary representation \(C\) of the form
\[
\begin{bmatrix}
X & Y \\
-Y & X
\end{bmatrix}
\]
given by \(V : A \sim C \bar{C}\), where \(V_1, \ldots, V_p\) are arbitrary unitary matrices such that
\[V_i^T \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} V_i = S_i\]
(they exist by Lemma 4.2(b)).
Proof. (a) Let $R : A \simto C B$, where $B$ is a Euclidean representation. Then

$$R^T = \bar{R}^{-1} : \bar{B} \simto C \bar{A}, \quad H := R^T R : A \simto C \bar{A}$$

(observe that $H = H^T$).

(b) Let $A$ be an indecomposable unitary representation and $S : A \simto C \bar{A}$. Then $\bar{S}S : A \simto C A$, by Theorem 3.1(b)

$$\bar{S}S = \lambda 1_A, \quad S = \lambda \bar{S}^{-1} = \lambda S^T = \lambda (\lambda S^T)^T = \lambda^2 S,$$

and $\lambda \in \{1, -1\}$.

(i) Let $\lambda = 1$, $U : A \simto C B$ and $U^T U = S$. Then

$$U = (U^T)^{-1} S = \bar{U} S : A \simto C \bar{B}$$

and $B = \bar{B}$.

(ii) Let $\lambda = -1$. Then $A$ is not isometric to a Euclidean representation (otherwise, by (a) there exists

$$H = H^T : A \simto C \bar{A};$$

by Theorem 3.1(b)

$$S^{-1}H = \mu 1_A, \quad H^T = \mu S^T = -\mu S = -H,$$

a contradiction). Let $V : A \simto C C$, where

$$V_i^T \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} V_i = S_i.$$

Then

$$V S V^{-1} : C \simto C \bar{C}.$$

If $\alpha$ is an arrow of $Q$, then

$$\begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} C_\alpha = \bar{C}_\alpha \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix}$$

and $C_\alpha$ is of the form

$$\begin{bmatrix} X & Y \\ -\bar{Y} & \bar{X} \end{bmatrix}.$$
Applying this theorem to unitary representations of the quiver $\xymatrix{ & \bullet \\ \bullet \ar[ru] }$, we obtain

**Corollary 4.1.** Let $A$ be a complex matrix that is not unitarily similar to a direct sum of matrices, and let $S^{-1}AS = \bar{A}$ for a unitary matrix $S$ (such $S$ exists if $A$ is unitarily similar to a real matrix). Then $A$ is unitarily similar to a real matrix if and only if $S$ is symmetric. $\square$
