ABSTRACT

Objective: The purpose of this work was to enhance oral bioavailability of metformin by incorporation of different amino acid residues through the glycolic acid spacer.

Methods: Two series of metformin derivatives (V a-e) and (VI a-e) were synthesized by incorporation of five amino acids (glutamic acid, alanine, phenylalanine, proline and GABA amino butyric acid) and their methyl esters respectively into metformin through glycolic acid spacer and preliminary evaluation for the antihyperglycemic activity was carried out using streptozotocin-induced diabetic rats model.

Results: In vivo anti-hyperglycemic activity of the final compounds (V a-e) and (VI a-e) showed that compounds (V b, V c, VI c and V e) produced higher percent of decrease in blood glucose level compared to metformin after 5 h of the treatment while compounds (VI b, VI c, VI d, VI e and VI e) showed profound effect after 24 h of the treatment. Although compounds (V a, VI a, V b and V c) showed a significant decrease in blood glucose level at 5 h but their effect diminished at 24 h. Compound (V e) showed higher antihyperglycemic effect than metformin and its effect continued up to 24 h.

Conclusion: From this study, it was concluded that incorporation of these amino acids or their methyl esters maintained or enhanced the antihyperglycemic effect of metformin.

Keywords: Metformin, Intestinal di/tripeptide transporter, Amino acids, In vivo anti diabetic study

INTRODUCTION

Metformin is a widely prescribed antihyperglycemic agent used for the treatment of type II diabetes mellitus which is a global disease estimated to affect around 438 million people by 2030 [1]. Metformin plays an effective role in the treatment of polycystic ovary syndrome [2], cardiovascular disease [3], dyslipidemia [4] and in cancer treatment [5].

The main effect of metformin is to decrease hepatic glucose production, mostly through a mild and transient inhibition of the mitochondrial respiratory chain complex 1 [6]. The resulting decrease in hepatic energy activates the AMP-activated protein kinase (AMPK), a cellular metabolic sensor [7]. Furthermore, metformin cardiovascular, metabolic and antiproliferative effect is thought to be elicited by AMPK-mediated pathways [8].

Metformin is very hydrophilic with a net positive charge at physiological pH. It accumulates in the intestinal environment, and thus it is poorly absorbed with an oral bioavailability range between 40%-60% [9]. It accumulates in the GI tract [10]. The attached moiety acts as a recognition site so as to make it acceptable for the transport across the intestinal wall thereby augmenting metformin absorption from the GI tract [11]. This presents the opportunity to synthesise new derivatives of metformin by incorporation of different amino acid residues and their esters through a glycolic acid spacer to enhance metformin bioavailability.

MATERIALS AND METHODS

all reagents and anhydrous solvents were of analar type, were purchased from (Avonchem, England, Scharlau, Spain, Sigma Aldrich, Germany, BDH, England, Avantor, Netherlands). Metformin HCl is supplied from (Pioneer, USA). Electrothermal melting point apparatus (Stuart, England) and open capillary tubes were used to determine the melting points and are uncorrected. Thin layer chromatography was run on TLC silica gel (50 F254, Merck (Germany), for checking the purity of the products as well as monitoring the progress of the reaction. Chromatograms were eluted by using three different solvent systems: A: chloroform: methanol: ammonia 3:1:1; B: methanol: ammonium sulfate: water 10:10:1; C: methanol: ammonium sulfate: water 10:10:1. Compounds were revealed upon irradiation with UV light [15]. IR spectra were recorded on a FTIR, Shimadzu 4000s spectrometer as KBr and NaCl discs in College of Pharmacy, Al-Mustansiriyah University, Baghdad, Iraq. 1H NMR spectra were recorded on Bruker model Ultra shield 300 MHz spectrometer using DMSO solution in Al al-bayt University, Jordan. CHNS microanalysis was performed using a Euro-Vector EA3000 (Italy) in Al al-bayt university, Jordan. The general routes outlined in Scheme 1 were used for the synthesis of all compounds.

Synthesis of metformin derivatives

Synthesis of amino acid methyl esters hydrochloride (II a-e)

Thionyl chloride (0.01 mole, 2 ml) was slowly added to methanol (40 ml), cooled at 0 °C on an ice bath and the amino acids (0.01 mol) was added to it. The mixture was refluxed for 6 h with continuous stirring, and the reaction was monitored by the evolution of HCl gas which is detected by changing the color of pH graduated litmus paper into reddish when placed on the top of the condenser. The excess of thionyl chloride and the solvent was evaporated under reduced pressure by using a rotary evaporator to give aminomethyl ester hydrochloride [16].
Synthesis of aminomethyl ester-chloroacetylchloride derivatives (IV a-e)

0.01 Mol of amino acid ester (III a-e) was dissolved in DMF: benzene mixture (1:3) 40 ml, then TEA (0.01 mol) was added. The reaction mixture was stirred in an ice bath and chloroacetylchloride (0.01 moles in 10 ml benzene) was added dropwise with continuous stirring over a period of 1 hr. at –10 °C, followed by reflux for 3 h. The mixture was cooled by addition of cold to give an oily product [17].

Synthesis of metformin-aminomethyl ester series (V a-e)

A mixture of amino acid ester-chloroacetylchloride derivatives (0.01 mol), metformin (0.01 mol), TEA (0.01 mol) and potassium iodide (0.01 mol) in DMF (25 ml) was stirred overnight at room temperature. The reaction mixture was poured into crushed ice with stirring and extracted with chloroform (4×25 ml). The aqueous layer was washed with 2% sodium thiosulphate (3×25 ml), 5% HCl (3×25 ml), 5% NaOH (3×25 ml) and finally with brine solution (2×25 ml). The aqueous layer was dried over anhydrous sodium sulphate, filtered and the solvent was removed under reduced pressure [18].

Synthesis of metformin–amino acid series (VI a-e)

Methanol (50 ml) was added to the oily product of Metformin–amino acid ester compound V a-e (0.005 mol). The reaction was cooled down to 18 °C, and then sodium hydroxide (1N, 5 ml) was added dropwise, with continuous stirring over a period of 30 minutes. Stirring was continued at 18 °C for additional 5 h. The reaction mixture was acidified with HCl (1N, 5 ml), and then the excess of cold water was added. Methanol was evaporated under reduced pressure, and the acidic compound was precipitated [19].

Characterization

Glycine methyl ester hydrochloride (II a)

White crystal; % yield: 93%; melting point: 175 °C; Rf 0.66 (chloroform: methanol) (8.5:1.5) and Rf 0.40 (methanol: ammonium sulfate 10%; water) (1:10:1); IR (KBr) Vₘₐₓ (cm⁻¹): 2800-3200 (primary amine salt overlapped with CH); 1751 (C=O of ester).

Alanine methyl ester hydrochloride (II b)

White crystal; % yield: 97%; melting point: 111 °C; Rf 0.45 (chloroform: methanol) (8.5:1.5) and Rf 0.36 (methanol: ammonium sulfate 10%; water) (1:10:1); IR (KBr) Vₘₐₓ (cm⁻¹): 3400 (NH stretching); 1750 (C=O of ester).

Phenyl alanine methyl ester hydrochloride (II c)

White powder; % yield: 80%; melting point: 163 °C; Rf 0.70 (chloroform: methanol) (8.5:1.5) and Rf 0.59 (methanol: ammonium sulfate 10%; water) (1:10:1); IR (KBr) Vₘₐₓ (cm⁻¹): 2800-3100 (primary amine salt overlapped with CH); 1750 (C=O of ester); 1581 (C=C aromatic).

Proline methyl ester hydrochloride (II d)

White powder; % yield: 75%; melting point: 205 °C; Rf 0.46 (chloroform: methanol) (8.5:1.5) and Rf 0.32 (methanol: ammonium sulfate 10%; water) (1:10:1); IR (KBr) Vₘₐₓ (cm⁻¹): 3300-3600 (NH stretching); 1747 (C=O of ester).
GABA amino butyric methyl ester (II e)

Oily; % yield: 90%; boiling point: 110 °C; R = 0.60 (chloroform: methanol) (8.5:1.5) and R = 0.40 (methanol: ammonium sulfate 10%: water) (1:10:1); IR (NaCl) V_max (cm⁻¹): 3009 (primary amine salt stretching); 1750(C=O of ester).

Methyl 2-(2-chloroacetamido) acetate (IV a)

Oily; % yield: 60%; boiling point: 104 °C; R = 0.46 (chloroform: methanol) (8.5:1.5) and R = 0.35 (methanol: ammonium sulfate 10%: water) (1:10:1); IR (NaCl) V_max (cm⁻¹): 3275 (NH stretching of amide); 1745(C=O of ester); 1666(C=O of amide); 1498 (C=C aromatic).

Methyl 2-(2-chloroacetamido) pyrrolidine-2-carboxylate (IV b)

Oily; % yield: 65%; boiling point: 135 °C; R = 0.55 (chloroform: methanol) (8.5:1.5) and R = 0.45 (methanol: ammonium sulfate 10%: water) (1:10:1); IR (NaCl) V_max (cm⁻¹): 1743(C=O of ester); 1651(C=O of amide); 1500 (C=N of imine).

Methyl 4-(chlorocarbonyl) amino butanoate (IV c)

Oily; % yield: 73%; boiling point: 155 °C; R = 0.65 (chloroform: methanol) (8.5:1.5) and R = 0.63 (methanol: ammonium sulfate 10%: water) (1:10:1); IR (NaCl) V_max (cm⁻¹): 3417 (NH stretching of amide); 1745(C=O of ester); 1653(C=O of amide).

Methyl 3, 5-diimino-2-methyl-8-oxo-10-phenyl-2, 4, 6, 9-tetraazaundecan-11-oate (V a)

White powder; % yield: 58%; melting point: 265 °C; R = 0.26 (methanol: ammonium sulfate 10%: water) (1:20:1); IR (KBr) V_max (cm⁻¹): 3300-3650 (Broad OH stretching overlap with NH of secondary amine); 1650-1710 (Broad band due to C=O of ester overlap with C=O of amide); 1591 (broad band C=N of imine); 1415, 1480, 1447 (C=N of imine). 1HNMR (300MHZ, DMSO) (δ ppm): 1.99-2.17 (m,7H, CH aromatic); 1.41(d,3H,CH of alanine); 3.59(s,2H, N=CH); 3.72(s,3H, OCH3); 4.45 (s,2H,CH2 of glycine); 6.69(s,3H, NH of amine and imine); 7.72(s,1H, NH of glycine). Anal. calcd. For C22H18N3O3: C, 59.67; H, 5.43; N, 15.01. Found C, 59.67; H, 5.29; N, 15.04.

Methyl 3, 5-diimino-2-methyl-8-oxo-2, 4, 6, 9-tetraazaundecan-11-oate (V b)

Yellow powder; % yield: 50%; melting point: 265 °C; R = 0.30 (methanol: ammonium sulfate 10%: water) (1:20:1); IR (KBr) V_max (cm⁻¹): 3300-3660 (Broad OH stretching overlap with NH of secondary amine); 1650-1710 (Broad band due to C=O of ester overlap with C=O of amide); 1593 (broad band C=N of imine). 1HNMR (300MHZ, DMSO) (δ ppm): 3.01(s,1H,NH); 3.15(s,6H, N-CH3); 3.54(s,2H,CH2); 4.80 (s,2H,CH2); 6.98-6.94(s,3H, NH of amine and imine); 7.71(s,1H, NH of glycine). Anal. calcd. For C22H22N2O3: C, 53.88; H, 6.63; N, 18.51. Found C, 53.88; H, 6.9; N, 18.40.

Methyl 3, 5-diimino-2-methyl-8-oxo-10-phenyl-2, 4, 6, 9-tetraazaundecan-11-oate (V c)

Yellow powder; % yield: 54%; melting point: 280 °C; R = 0.26 (methanol: ammonium sulfate 10%: water) (1:20:1); IR (KBr) V_max (cm⁻¹): 3000-3600 (Broad OH stretching overlap with NH of secondary amine and CH aromatic); 1674 (Broad band belongs to C=O of ester stretching vibration of carboxylic acid and amide); 1556 (C=C aromatic). 1HNMR (300MHZ, DMSO) (δ ppm): 3.47 (s,6H, N-CH3); 3.09(s,6H, N-CH3); 3.34,3.93(d,2H,CH2-Ar); 4.33 (2H,CH2); 6.27(t,1H,CH of phenyl alanine); 6.90-7.00(s,3H, NH of amine and imine). 7.34-7.66(m,6H,Ar), 8.67 (s,1H, NH) 11.04(s,1H,COOH). Anal. calcd. For C25H15N3O3: C, 53.88; H, 6.63; N, 25.13. Found C, 53.61; H, 6.41; N, 25.00.
**Evaluation of anti-hyperglycemic activity**

The protocol of this work was approved by the ethical committee of the college of pharmacy/Al-Mustansiriyia University (AEC file no. 3 dates 20-04-2015). In vivo antidiabetic activity of the chemically synthesised compounds (V a-e) and (VI a-e) were evaluated using streptozotocin-induced diabetes in rats [20]. Their evaluation for antidiabetic activity based on the percent decrease in blood glucose level in comparison to standard metformin treatment [21].

**Method of assessment**

Albino rats of either sex weighing (200±10 g) were supplied by National Center for Drug Control and Research, Iraq and were housed in College of Pharmacy/University of Al-mustansiriya under standardised conditions, 12 h light-dark cycle. Animals were fed commercial chow and had free access to water and libitum. Diabetes was induced by intraperitoneal injection of streptozotocin (60 mg per Kg) and rats were divided into 13 groups (each group consists of 6 rats) as follow: Group 1: six non-diabetic rats served as negative control and treated with the (0.5 ml) vehicle (water).

Group 2: six diabetic rats served as positive control and treated with the vehicle (water). Group 3: six rats treated with metformin as reference substance in a dose of 150 mg/kg dissolved in distilled water (orally via gavage needle) [22]. Group 4-13: six diabetic rats treated orally via gavage needle with the tested (V a-e) and (VI a-e) dissolved in distilled water in doses that determined below.

**Calculation for dose determination**

150 mg/kg/165.62 = Dose/M. Wt. of the tested compounds (Metformin M. Wt = 165.62 g/mol) table 1. 

**Experimental design**

Rats were adapted for 7 d then diabetes was induced by intraperitoneal injection of streptozotocin (60 mg/kg), which was dissolved in distilled water and always prepared freshly for immediate use within 5 min. After 48 h, rats werestarved overnight, and fasting blood glucose level was checked for each rat via glucometer (ACCU-CHECK). Depending on the negative control findings table 2, rats with hyperglycemia (fasting blood glucose>100 mg/dl) [23] considered to be diabetic. Metformin treatment and the tested compounds were administered orally via gavage needle and blood glucose level for each rat was measured via glucometer at seven-time intervals (0, 0.5, 1, 2, 4, 5, and 24 hr) after drug administration.

**Statistical analysis**

The data are expressed as the mean±SEM and analysed for statistical significance using student t-test (Two-Sample Assuming Equal Variances) for comparison between mean values. Comparisons between different groups were made using ANOVA (one-way analysis using GraphPad prism 7 software) Probability (P) value of less than 0.05 was considered significant.

**RESULTS AND DISCUSSION**

Six compounds (V b, VI b, VI c, V d, VI d and V e) produced significant decrease in blood glucose level at 4 h compared to untreated animals while compounds (V a and V c) showed significant decrease in blood glucose level at 5 h after treatment (*: p<0.05, **: p<0.001) table 3.

Compounds (V b, V c, VI c and V e) produced higher percent of decrease in blood glucose level (68.9%, 59.9%, 66% and 58%) respectively, compared to metformin (50%) at 5 h while compounds (VI b, VI c, V d, VI d, V e and VI e) showed higher percent of decrease in blood glucose level (50%, 54%, 58%, 53%, 59% and 53%) respectively compared to metformin (41%) after 24 h as presented in fig. 1 and 2.

The kinetic profile of the tested compounds seemed to be close to metformin kinetic profile where the effect of most tested compounds started at 4 h and almost finished at 24 h as presented in fig. 3and 4.
Compounds (V a, VI a, V b and V c) showed significant decrease in blood glucose level at 5 h (47.2%, 48.4%, 68.9% and 59.8%) respectively, however their effect diminished after 24 h with percent decrease in blood glucose level equal to (20.8%, 18.2%, 24.8% and 12.4%) respectively.

Compound (V e) showed higher anti-hyperglycemic effect than metformin where its effect continued up to 24 hr.

Compounds (V a-e) exerted profound reduction in blood glucose level compared to metformin which might be due to the protonated metformin molecule at physiological pH with pKa 11.5 so it can only marginally pass the lipid membrane with an oral bioavailability range between 40%-60% while incorporation of amino esters into metformin increase metformin absorption through intestine [24, 25]. Jing Sun et al. (2010) found that the intestinal absorption of [3-(hydroxymethyl) phenyl] guanidine was enhanced by incorporation of amino acid esters [26].

Generally, compounds with free carboxylic acid moiety have a higher anti-hyperglycemic effect than corresponding ester derivatives or parent compound metformin which might be due to their utilisation by intestinal peptide transporters as suggested by Tamai et al. (1998) during enhancement of the intestinal absorption of L-DOPA incorporated into L-phenylalanine [27].

Table 3: Effects of metformin (STD) and the tested compounds (V a-e) and (VI a-e) on blood glucose level (mg/dL)

| Compounds | Time | 0 h | 0.5 h | 1 h | 2 h | 4 h | 5 h | 24 h |
|-----------|------|-----|-------|-----|-----|-----|-----|------|
| Post. cont. |      | 131.3±22.4 | 130.1±22.1 | 132.7±22.7 | 135.7±23.4 | 141.6±23.7 | 148.7±24.9 | 170±25.9 |
| STD       |      | 170.5±18.6 | 161.8±22 | 139.3±18 | 114.7±18.8 | 93.5±15.5** | 80.8±13.8** | 82.5±17.3* |

Each value represents the mean±SEM **: p<0.001, *: p<0.05, ns: non-significant compared to untreated animals using one-way ANOVA analysis, n=6, post. cont; positive control, STD; metformin standard treatment, V a-e; metformin derivatives of ester series, VI a-e; metformin derivatives of acid series.

Fig. 1: Percent decrease in blood glucose level for metformin (STD), and the tested compounds (V a-e) and (VI a-e) after 5 h. Results are expressed as mean±SEM (n= 6). ANOVA one-way analysis was used for statistical analysis

Fig. 2: Percent decrease in blood glucose level for metformin (STD), and the tested compounds (V a-e) and (VI a-e) after 24 h. Results are expressed as mean±SEM (n= 6). ANOVA one-way analysis was used for statistical analysis
CONCLUSION

In vivo antidiabetic study showed that the incorporation of amino acids or their methyl esters into metformin molecule maintained or enhanced its anti-hyperglycemic effect which might be due to enhanced bioavailability of these series by enhanced passive diffusion and/or enhanced binding to intestinal di/tripeptide transporters (PepT1) which are expressed in small intestine or may have additional or different mechanism of hypoglycemic effect. (Further investigation in this area is required).

ACKNOWLEDGEMENT

The authors are thankful to the laboratory for pharmaceutical Chemistry and the animal house in Al-mustansiriya University, Baghdad, Iraq, for providing the necessary facilities to conduct research work. We would also like to acknowledge the support received from assistant Prof. Dr. Ghaith Ali Jasim while conducting the research work.
