College of Animal Science and Technology, Hunan Agricultural University, Changsha, China

The study investigated the impact of fermented cottonseed meal (FCSM) on growth performance, immunity and antioxidant properties, nutrient digestibility, and gut microbiota of weaned piglets by replacing soybean meal with FCSM in the diet. The experimental piglets were fed with either the soybean meal diet (SBM group) or fermented cottonseed meal diet (FCSM group) for 14 days after weaning. The digestibility of dry matter (DM), organic matter (OM), crude protein (CP), gross energy (GE), amino acids and nitrogen was higher in the FCSM diet than those in the SBM diet (p < 0.05). The piglets in the FCSM group showed greater growth performance and lower diarrhea rate than those in the SBM group (p < 0.05). The concentration of serum immunoglobulin G (IgG) and antioxidase, intestinal and hepatic antioxidase were increased and the concentration of malondialdehyde (MDA) in the serum was decreased in those piglets in the FCSM group compared to those piglets in the SBM group (p < 0.05). The piglets in the FCSM group had a higher concentration of volatile fatty acids (VFAs) in their ileum and cecum and a higher Simpson index of ileum than piglets in the SBM group (p < 0.05). The relative abundance of Lactobacillus and [Ruminococcus]_torques_group in ileum and Intestinibacter, norank_f_Muribaculaceae, unclassified_o_Lactobacillales and [Eubacterium]_coprostanoligenes_group in cecum were enhanced in piglets fed with the FCSM diet, whereas the relative abundance of Sarcina and Terrisporobacter were increased in piglets fed with the SBM diet. Overall, FCSM replacing SBM improved the growth performance, immunity and antioxidant properties, and nutrient digestibility; possibly via the alterant gut microbiota and its metabolism of weaned piglets.

Keywords: fermented cottonseed meal, growth performance, immunity and antioxidant capacity, gut microbiota, weaned piglets
INTRODUCTION

Soybean meal (SBM), an important protein source in the livestock industry, is highly recognized for its significant protein content and widespread availability (Azarm and Lee, 2014; Kim, 2014). However, the price of SBM has increased dramatically and the supply of high-quality protein feeding ingredients (such as SBM and fish meal) has been deficient in recent years. This leads to a higher livestock breeding expense and restricts the development of animal husbandry. Therefore, there is an urgent need for more alternative high-quality protein feeding ingredients to solve the protein source crisis in animal husbandry.

Cottonseed meal (CSM), a by-product obtained from the process of extracting the oil from cotton seed, is an attractive alternative protein source for livestock diets (Nagalakshmi et al., 2007). However, compared to SBM, the application of CSM as a feed ingredient in animal husbandry is limited due to the presence of anti-nutritional factors (Lordelo et al., 2007; Tang et al., 2012) such as free gossypol, cycloproponoic fatty acids, and crude fiber, which may cause negative effects on growth performance and organ functionality (Nie et al., 2015; Świątkiewicz, 2016). Fermented cottonseed meal (FCSM), a product produced by mixing solid CSM with liquid phases and then inoculating the mixture with beneficial microorganisms (Sun et al., 2014), can reduce free gossypol and improve the protein quality of CSM with solid state fermentation (Zhang et al., 2007). It has been suggested that the FCSM partial replacing SBM (about 6–8%) not only can improve the growth performance, immune and antioxidant capacity, and digestibility in broiler chickens (Sun et al., 2013; Nie et al., 2015; Wang et al., 2017; Niu et al., 2020), but also can reduce the F:G (the ratio of feed and gain weight) and diarrhea rate in nursery pigs, growing pigs and finishing pigs (Guan et al., 2017), which indicated that the FCSM has the potential to be a high-quality protein source.

Weaned piglet is a critical group in whole pig production, which consumes a large amount of high-quality protein ingredients. However, there is a lack of relevant research on the application of FCSM in weaned piglets. Therefore, the present study aimed to compare the effects of dietary SBM and FCSM on growth performance, immunity and antioxidant properties, nutrient digestibility, and gut microbiota of weaned piglets.

MATERIALS AND METHODS

The animal handling and all procedures of this study received approval from the Animal Care and Use Ethics Committee of the Hunan Agricultural University (Changsha). The FCSM used in this experiment was provided by the Tycoon Group (Xinjiang, China). The SBM used in this experiment was provided by Hunan Lifeng Biological Technology Co., Ltd. (Hunan, China). Table 1 shows the nutrient composition of SBM and FCSM.
Animal Treatment and Experimental Design

A total of 32 Duorc × (Landrace × Yorkshire) growing barrows, with an average initial body weight (BW) of 7.85 ± 0.49 kg, were allotted to two dietary treatments in a completely randomized design with 16 repetitions per treatment according to their body weight. The dietary treatments include SBM diet and FCSM diet; the FCSM diet was formulated by adding 6% FCSM to replace the SBM compared with the SBM diet, and corn and soy oil was changed to balance the energy and protein levels (Table 2). The experimental diets and vitamin-mineral premix were configured to meet the nutritional needs of nursery piglets as recommended by the NRC (2012). The experimental period lasted for 14 days. The house, feed trough and drinker were thoroughly cleaned and disinfected before starting the experiment. The temperature of the pig house was kept at 24–28°C, and the relative humidity was controlled at 60–70%. All the pigs were provided ad libitum access to water and feed. The daily feed intake and BW of each pig were recorded on day 0 and day 14 to calculate the average daily gain (ADG), average daily feed intake (ADFI), and feed conversion rate (ADG:ADFI, G:F). A scoring system was applied to indicate the presence and severity of diarrhea as following: 1 = hard feces; 2 = slightly soft feces; 3 = soft, partially formed feces; 4 = loose, semiliquid feces; and 5 = watery, mucous-like feces.

Sample Collection

By the end of the experiment, six samples of blood (10 ml) were collected from the precaval veins of each group of piglets after fasting for 12 h. After standing the blood samples for 1 h at 4°C, they were centrifuged at 3,000 x g for 15 min at 4°C, whereupon the serum samples obtained were immediately stored at −80°C for immunoglobulin and antioxidant indices analysis including immunoglobulin A (IgA), immunoglobulin G (IgG), immunoglobulin M (IgM), superoxide dismutase (SOD), glutathione peroxidase (GSH-Px), total antioxidant capacity (T-AOC), and malondialdehyde (MDA). After the blood collection, six piglets closest to the average BW from each group were slaughtered, and then the jejunum, ileum and liver, were sampled through a sterile laparotomy, which was collected in centrifuge tubes and immediately placed in liquid nitrogen and then stored at the temperature of −80°C for analysis of antioxidant indices levels of SOD, GSH-Px, catalase (CAT), T-AOC and MDA in jejunal, ileal and liver tissue. Besides, the ileum and cecum segments were isolated to collect the digesta samples using centrifuge tubes and a part of them

Frontiers in Microbiology | www.frontiersin.org
immediately placed in liquid nitrogen and then stored at the temperature of $-80^\circ C$ for analysis of microbiome and metabolite. The rest of samples were stored at $-20^\circ C$ for subsequent chemical composition analysis to calculate nutrient digestibility.

**Determination of the Digestibility of Nutrients and Amino Acids**

The feed samples and ileal digesta after freeze-drying were weighed in parallel samples for analysis and determination. Dry matter (DM), organic matter (OM), crude protein (CP), and gross energy (GE) contents were determined following the AOAC (2006) procedures. The amino acid (AA) profiles were detected by High Performance Liquid Chromatography (HPLC; Agilent 1200, Agilent Technologies, United States). Lysine and threonine were detected after hydrolyzing with 6 mol/L HCl at 105°C for 24 h. Methionine was analyzed as methionine sulfone after cold performic acid oxidation overnight before hydrolysis. Tryptophan was determined after hydrolyzing with 4 mol/L LiOH at 110°C for 20 h. The contents of acid insoluble ash (AIA) were determined in accordance to the method of Keulen and Young (1977) and the apparent ileal digestibility (AID) of amino acids and nitrogen was calculated as described by Stein et al. (2007).

**Immunoglobulin and Antioxidant Indices Analysis**

Frozen jejunal, ileal and liver tissue (2 mg) in 2 ml of phosphate-buffered saline was homogenized on ice with an Ultra-Turrax homogenizer (Bioblock Scientific, Illkirch, France) for 10 s at 6,800 rpm. The homogenate was centrifuged at 950 × g for 10 min at 4°C, and the supernatant was stored in a 2 ml centrifuge tube at $-80^\circ$C until analysis. The GSH-Px and CAT activities, T-AOC, and MDA concentrations in the jejunal, ileal and liver tissue and serum were assayed using a UV/visible spectrophotometer (UV-2450; Shimadzu, Kyoto, Japan). The assays were conducted using assay kits purchased from Nanjing Jiancheng Institute of Bioengineering (Nanjing, Jiangsu, China) and conducted according to the manufacturer's instructions. All samples were measured in triplicate, at appropriate dilutions, and the activities of the enzymes were estimated from the linear range of standard curves constructed with the pure enzymes. The protein concentration of the supernatants was determined using Coomassie Brilliant Blue G250 (BlueGene, Shanghai, China).

**Analysis for VFAs Using a Gas Chromatographic Method**

The concentration of volatile fatty acids (VFAs) including short chain fatty acids (SCFAs) and branched chain fatty acids (BCFAs) in digesta were analyzed using a gas chromatographic method. Briefly, approximately 1.0 g of digesta samples were first homogenized in the 1.5 ml deionized water. After being centrifuged at 15,000 × g at 4°C for 10 min, supernatants (1 ml of each) were acidified with 25% metaphosphoric acid at a 1:5 ratio (1 volume of acid for 5 volumes of sample) for 30 min while on ice. The sample was injected into a GC 2010 series gas chromatograph (Shimadzu, Japan) equipped with a CP-Wax 52 CB column 30.0 m × 0.53 mm i.d (Chrompack, Netherlands). The injector and detector temperatures were 75 and 280°C, respectively. All procedures were performed in triplicate and total VFAs were determined as the sum of analyzed SCFAs (acetate, propionate, butyrate, and valerate) and BCFAs (isobutyrate and isovalerate).

**Analysis for Bacterial Microbiota by 16S RNA**

Total genomic DNA of 12 digesta samples were extracted using a Stool DNA Isolation Kit (Tiangen Biotech Co., Ltd., Beijing, China) following the manufacturer's instructions. The quantity and quality of extracted DNAs were measured using a NanoDrop ND-1000 spectrophotometer (Thermo Fisher Scientific, United States) and agarose gel electrophoresis, respectively. The genes of bacteria 16S ribosomal RNA in the region of V4–V5 were amplified by using polymerase chain reaction (PCR) with primers (515F 5'-barcode- GTGCCAGCMGCGCGCCG-3' and (907R 5'-12OOGCTCGATTTAGGGT-3'). Electrophoresis was applied to analyze the integrity of PCR amplicons by using a TapeStation Instruction (Agilent technologies, United States). AxyPrep DNA Gel 122 Extraction Kit was chosen to extract and purify PCR amplicons using 2% agarose gels (Axygen 123Biosciences, Union City, CA, United States) and then the production was quantified using QuantiFluor™-ST and sequenced on an Illumina MiSeq system. QIME software was used to demultiplex and quality-filtered raw Illumina fastq files. Operational taxonomic units (OTUs) were defined as a similarity threshold of 0.97 using UPARSE. Then UCHIME was applied to identify and delete the abnormal gene sequences. RDP database1 was also referenced to take the taxonomy-based analysis for OTUs using RDP classifier at a 90% confidence level. The α-diversity indices including Simpson and Chao1 were analyzed by Mothur v.1.30.2. Principal co-ordinates analysis (PCoA) tools in R language were used for PCoA. The histogram of linear discriminant analysis (LDA) distribution was implemented using LDA effect size analysis (LEfSe) software.

**Statistical Analysis**

All data were analyzed by the GLM procedure of SPSS 21.0 (SPSS Inc., Chicago, IL, United States), and each piglet was regarded as a statistical unit. Data are showed as Mean values with standard error of the total mean (SEM). For all tests, $p<0.05$ was considered as significant difference, while 0.05 < $p$< 0.10 as a tendency.

**RESULTS**

**Growth Performance**

Over the experimental period, it has been noticed that piglets in the FCSM treatment had higher the final BW, ADG, and G:F ($p<0.05$) and lower diarrhea incidence compared to those in the SMB treatment ($p<0.05$; Table 3). No difference was observed in ADFI between the two dietary treatments (Table 3).

TABLE 3 | Effects of two protein source on performance of weaned piglets.

| Items               | SBM  | FCSM | SEM  | p     |
|---------------------|------|------|------|-------|
| Initial BW, kg      | 7.79 | 7.78 | 0.04 | 0.89  |
| Final BW, kg        | 11.68| 12.04| 0.08 | 0.03  |
| ADG, g              | 277.86| 304.29| 7.12 | 0.04  |
| ADFI, g             | 441.05| 454.16| 9.17 | 0.46  |
| G:F                 | 0.63 | 0.67 | 0.01 | 0.03  |
| Diarrhea incidence, %| 4.78 | 2.42 | 0.47 | 0.02  |

Data were shown as the mean with the SEM (n = 16). BW, body weight; ADG, average daily gain; ADFI, average daily feed intake; G:F, ADG:ADF; SBM, soybean meal; FCSM, fermented cottonseed meal.

**Nutrient Digestibility**

As shown in Table 4, the FCSM diet had higher apparent total tract digestibility and ileal digestibility of nutrients in terms of DM, OM, CP, and GE than the SBM diet (p < 0.05). Moreover, higher AID of essential AA including histidine, isoleucine, leucine, phenylalanine, valine, and nonessential AA including asparagine were discovered in the FCSM group compared to that in the SBM group (p < 0.05, Table 5). Furthermore, the AID of total nitrogen was enhanced in the FCSM group in comparison with the SBM group (p < 0.05).

**Immunity and Antioxidant Properties**

The results have shown that piglets in the FCSM group had higher serum IgG (p < 0.05) than those in the SBM group (Table 6). However, no significant difference was observed in terms of serum IgA and IgM (p > 0.05) of weaned piglets between the two groups. The effects of FCSM and SBM on serum, intestine and liver antioxidant enzyme activity and oxidant products on weaned piglets have been shown in Table 7. Compared with the SBM group, the SOD and GSH-Px in serum, jejunum, and ileum were improved on the piglets in the FCSM group (p < 0.05). Moreover, the jejunal T-AOC and the liver GSH-Px were enhanced on the piglets in the FCSM group (p < 0.05). Furthermore, the serum MDA was reduced on the piglets in the FCSM group (p < 0.05).

**VFAs Composition**

The VFAs composition in ileal and cecal digesta of weaned piglets were obtained in Table 8. Compared with the SBM group, the concentration of acetate, propionate, butyrate, isobutyrate, isovalerate, and total VFAs in ileal digesta of weaned piglets were increased in the FCSM group (p < 0.05). Similarly, the concentration of acetate, propionate, valerate, isobutyrate, isovalerate, and total VFAs in cecal digesta of weaned piglets were higher (p < 0.05) and the concentration of butyrate had a tendency to increase in the FCSM group (0.05 < p < 0.1).

**Gut Microbiota Diversity**

The OTUs of the ileal digesta from SBM and FCSM groups were 152 and 169, respectively, among which 82 common OTUs have been identified (Figure 1A). On the other hand, the OTUs of the cecal digesta from SBM and FCSM groups were 743 and 656, respectively, wherein 544 common OTUs have been identified (Figure 1B). The α-diversity of ileal and cecal microbiota including Simpson index and Chao1 index were presented in Figures 2A–D. The FCSM diet induced higher Simpson index of ileum than the SBM (p < 0.05), whereas no difference was shown in the other index between the two dietary treatments neither in the ileum nor cecum (p > 0.05). The β-diversity of bacterial community between SBM and FCSM was presented with PCoA (Figures 2E,F), showing a tendency of different clustering of microbial communities in cecum (0.05 < p < 0.1, Figure 2F).

At the phylum level, Firmicutes and Bacteroidetes were the dominant bacteria in both ileum and cecum. There was no difference found by the students’ tests in microbiota at the phylum level between the two treatment groups in ileum (p > 0.05; Figure 3A). However, the proportion of cecal Proteobacteria was decreased (p < 0.05) in the FCSM group compared with the SBM group (Figure 3C). Besides, at the genus level (Figures 3B,D), the proportion of ileal Lactobacillus was enhanced but the ileal unclassified_p_Firmicutes and cecal Ruminococcus_1 was decreased in the piglets in the FCSM group rather than that in the SBM group (p < 0.05).

The LEfSe analysis was used to identify the significantly different bacteria in the ileum and cecum between the two treatment groups from the phylum to genus level (Figures 3E,F). The relative abundance of Lactobacillus and [Ruminococcus]_torques_group in ileum and Intestinibacter, norank_f_Muribaculaceae, unclassified_o_Lactobacillales and [Eubacterium]_coprostanoligenes_group in cecum were enhanced in piglets fed with the FCSM diet than those fed with SBM diet, whereas the relative abundance of Sarcina and Terrisporobacter in ileum were decreased in piglets fed with the FCSM diet.

**DISCUSSION**

Cottonseed meal has not been widely used because it contains a large number of anti-nutritional factors, which result negative effects on growth performance, immune and antioxidant capacity and nutrient digestibility in animals (Nagalakshmi et al., 2007; Nie et al., 2015; Świątlikewicz, 2016). After going through solid
state fermentation, FCSM has much less free gossypol and other anti-nutritional factors, and definitively improved protein quality (Zhang et al., 2006, 2007; Sun et al., 2014; Wang et al., 2017). Sun et al. (2013) reported that the appropriate inclusion of FCSM replacing SBM improved the growth of yellow-feathered broiler chickens. Similarly, FCSM supplementation improved the ADG and G:F ratio of yellow-feathered broilers from the 43rd to 64th and the 21st to 64th day, respectively (Nie et al., 2013), which indicated that FCSM is beneficial for broilers as it enhanced their growth performance and digestion. Consistently, the current study showed that the piglets in the FCSM group presented greater growth performance and a lower diarrhea rate than those in the SBM group. The fermentation process of CSM might be one of the reasons, which effectively decreases free gossypol level, and increases acid-soluble protein level in CSM, and therefore further improves the digestive enzyme activity and nutrient digestibility in weaned piglets (Sun et al., 2014; Wang et al., 2017). This explanation has been confirmed by the nutrient digestibility of weaned piglets in FCSM and SBM treatments. The present results demonstrated that the apparent total tract digestibility and ileal digestibility of nutrients, essential and nonessential AA have been enhanced in piglets within the FCSM group.

Moreover, the microbial fermentation process can produce many beneficial substances, such as small-size peptides, exoenzymes, vitamins, organic acids, which can promote the

**TABLE 8** | Effects of protein source on volatile fatty acids composition in ileal and cecal digesta of weaned pigs (mg/g digesta).

| Items | SBM       | FCSM      | SEM    | p  |
|-------|-----------|-----------|--------|----|
| Ileum |           |           |        |    |
| Acetate | 0.70     | 0.83      | 0.02   | 0.01|
| Propionate | 0.35    | 0.42      | 0.01   | 0.01|
| Butyrate | 0.31     | 0.40      | 0.01   | <0.01|
| Valerate | 0.26     | 0.26      | 0.01   | 0.47|
| Isobutyrate | 0.09    | 0.05      | 0.01   | <0.01|
| Isovalerate | 0.22    | 0.17      | 0.01   | <0.01|
| Total VFAs | 1.93    | 2.13      | 0.01   | <0.01|
| Cecum  |           |           |        |    |
| Acetate | 3.79     | 4.43      | 0.07   | <0.01|
| Propionate | 2.72     | 3.36      | 0.18   | 0.04|
| Butyrate | 1.77     | 2.03      | 0.09   | 0.07|
| Valerate | 0.75     | 0.99      | 0.05   | 0.02|
| Isobutyrate | 0.41    | 0.31      | 0.02   | 0.01|
| Isovalerate | 0.61     | 0.47      | 0.02   | <0.01|
| Total VFAs | 10.06   | 11.60     | 0.27   | 0.01|

Notes:
1. Total VFAs = Acetate + Propionate + Butyrate + Valerate + Isobutyrate + Isovalerate.

Data were shown as the mean with the SEM (n=6). AA, amino acid; SBM, soybean meal; FCSM, fermented cottonseed meal.
The immunity of piglets is highly related to antioxidant capacity (Liu et al., 2021). Besides, antioxidase can improve the immunity by promoting the bacterial clearance and regulates phagocyte numbers (Peterman et al., 2015). In addition, a microbial FCSM increased the antioxidant activity in diets for Nile tilapia (Lim and Lee, 2011). Similarly, the present study showed that the antioxidation-related enzymes in serum, jejunum, ileum and liver were improved in piglets in the FCSM group compared with that in the SBM group. Additionally, the serum MDA was reduced in piglets in the FCSM group, which indicated that FCSM improved the antioxidative abilities compared with SBM (Wang et al., 2017). This may be one of the reasons that the improvement of growth performance in piglets has found in the FCSM group (Ma, X. et al., 2019; Ma, X. K. et al., 2019).

Many studies suggest that food or feeds fermented by probiotics may be potentially an effective strategy to regulate the gut microbiota and its metabolites (Azad et al., 2020; Niu et al., 2020; Gu et al., 2021; Li et al., 2021). The VFAs, especially butyric acid, as a microbial metabolite, can not only improve the growth performance, but also boost the immunity of piglets (Fang et al., 2014; Zhao et al., 2018). Zhao et al. (2018) reported that dietary fiber increases the butyrate-producing bacteria and improves growth performance of weaned piglets. Tsai et al. (2019) discovered that feeding sodium butyrate during the nursery phase tended to alter blood cell count and improve growth performance of weaned pigs. In the present study, the VFAs of ileum and cecum were increased in the FCSM group than that in the SBM group. This may explain the improved growth performance of piglets. Moreover, VFAs, as important intermediate products during anaerobic digestion, may influence the fermentation characteristics of hindgut (Jha and Berrocoso, 2016; Seradj et al., 2018). The protein fermentation metabolites in the hindgut are amines, SCFAs and BCFAs, among which amines must be converted from nitrogen-containing groups, while BCFAs are only produced from the fermentation of three branched chain amino acids, leucine, isoleucine and valine (Jha and Berrocoso, 2016; Seradj et al., 2018). Over-fermentation of protein in the hindgut is an important cause of diarrhea in piglets. The current study found that FCSM replacing SBM decreased the isobutyrate and isovalerate of the cecum, suggesting that FCSM reduced hindgut fermentation, which may be responsible for the reduced diarrhea rate in piglets.

In recent years, the interaction and connections between dietary protein, gut microbe and host has received increasing attention. Segmented exogenous microbiota transplantation proved the spatial heterogeneity of bacterial colonization along the gastrointestinal tract, i.e., the microbiota from one specific location selectively colonizes its homologous gut region (Li et al., 2020). The number of microorganisms in the hindgut was higher than that in the foregut (Jamet et al., 2011), which is consistent with the result in the present study. It has been previously shown that FCSM enhanced the Simpson index of

**FIGURE 1** | Effects of two protein sources on the ileac (A) and cecal (B) microbes at the operational taxonomic unit (OTU) in piglets. The individual minipig was regarded as the experimental unit (n=6). SBM, soybean meal; FCSM, fermented cottonseed meal.
ileum in piglets, which has a great contribution towards the improvement of intestinal health and maturation in piglets (Wang, X. et al., 2019). Lower protein concentration or better protein sources in the diets can improve hindgut health by preventing the proliferation of pathogenic bacteria and reduced the risk of colitis (Vidal-Lletjós et al., 2017; Najafabadi et al., 2019). Studies have shown that protein fermentation can change the composition and function of intestinal flora (Lu et al., 2019; Wang, H. et al., 2019). Consistently, in the present study, the analysis of the PCoA has shown that the microbial composition between the SBM and FCSM groups are slightly different.

Firmicutes and Bacteroidetes were the most dominant phyla in the pig (Chen et al., 2017). In our study, Firmicutes is the most dominant phyla in ileum and Firmicutes and Bacteroidetes in cecum. \textit{Lactobacillus}, as a potential probiotic, possesses the resistance to pathogen, anti-inflammatory and antioxidant capacity, and ability to improve of gut microbiota.
profile (He et al., 2019; Yang et al., 2020). Wang et al. (2017) has discovered that Lactobacilli and total anaerobic bacteria counts in ceca digesta of birds fed FCSM were improved compared with birds fed CSM on days 21 and 42. Likewise, the FCSM replacing the SBM has also enhanced the relative abundance of Lactobacillus of ileum and cecum.

**FIGURE 3** | Different microbiota comparison by the student t-test on Phylum and Genus of ileum (A,B) and cecum (C,D) was shown in (A–D). LDA effect size analysis (LEfSe) analysis showed significantly changed bacteria between SBM and FCSM group in ileum (E) and cecum (F). The individual minipig was regarded as the experimental unit (n = 6). SBM, soybean meal; FCSM, fermented cottonseed meal.
in the present study. He et al. (2019) has found that Lactobacillus johnsonii L531 reduced pathogen load and helped maintain SCFA levels in the intestine of pigs challenged with Salmonella enterica Infantis. Therefore, this might be one of the reasons that piglets in the FCSM group had higher level of VFAs than that in the SBM group. On the other hand, proteobacteria is the largest phylum of bacteria, including many pathogenic bacteria, such as Escherichia coli, Salmonella, Vibrio cholerae, Helicobacter pylori and other well-known species. In the current study, the relative abundance of Proteobacteria was decreased in piglets in the FCSM group, suggesting that the FCSM has the potential function to inhibit harmful bacteria, and improves the gut microbiota profile than SBM (Wang et al., 2017). In conclusion, FCSM replacing SBM improved the growth performance, immunity and antioxidant properties, nutrients digestibility possibly via the altering gut microbiota profile and its metabolites in weaned piglets.
