INTRODUCTION

Frank's sign (FS) is a diagonal earlobe crease running from the tragus to the edge of the auricle at an angle of approximately 45°. Sanders T. Frank first described it in 1973 as a dermatological finding predictive of coronary artery disease. Researchers have described FS in Italian Renaissance Art and in Greco-Roman sculptures. FS has been associated with the presence and severity of cardiovascular disease. The sensitivity and specificity of FS in predicting coronary artery disease were 80.65% and 44.15% in COPD patients, respectively. In this case, we present a patient with FS and multiple risk factors for cardiovascular disease presenting with myocardial infarction.
with right bundle branch block without dynamic ST-T changes. The cardiac ultrasound showed a normal left ventricle size with a mildly reduced ejection fraction of approximately 45%–50% with hypokinesia in the inferior wall. Troponin levels (at the time of presentation: <0.02 ng/mL → three hours later: 5.7 ng/mL) were increased. Furthermore, blood tests showed a normal renal function and increased LDL (96 mg/dL) and HbA1c (6.2%) levels.

The patient underwent an urgent coronary angiography due to the persisting symptoms, and a severe right coronary artery stenosis was found (Figure 1) without other significant findings. A percutaneous coronary intervention was performed with the placement of a drug-eluting stent in the culprit lesion. A detailed clinical examination revealed the presence of FS (Figure 2). The patient was discharged without complications.

3 | DISCUSSION

The pathophysiological basis for the relationship between FS and cardiovascular disease is unclear. The earlobe crease has been associated with the aging process, as suggested by excessive telomere loss. In addition, a recent histopathologic study showed a significant correlation between morphological changes of the myocardium and the presence of the earlobe creases, with arterial myoelastofibrosis, Wallerian-like degeneration in peripheral nerves, and deep-tissue fibrosis found in the base of the crease.

FS has been associated with the severity of coronary artery disease, as demonstrated by the SYNTAX score. Specifically, crossing creases not originating from the ear hole had the highest positive predictive value, and vertical creases on the face side had the highest negative predictive value for detecting intermediate and high SYNTAX scores. FS has been associated not only with the presence and severity of CAD but also with long-term prognosis. Specifically, in patients with myocardial infarction, the presence of FS was associated with an increased risk of death. The association of ear creases on the helix with coronary artery disease has also been proposed but needs more data to be confirmed.

By contrast, an observational study found no significant association between FS and abnormal ankle-brachial index. Furthermore, a recent systematic review showed that the diagnostic accuracy of diagonal earlobe crease for detecting chronic coronary syndromes is insufficient. Additionally, the Fremantle Diabetes Study assessed the clinical usefulness of FS as a sign of coronary artery disease or retinopathy in type 2 diabetes. This study found that FS was not a significant independent predictor of either coronary artery disease or retinopathy.

In the stroke setting, FS was more prevalent in patients with ischemic stroke than hemorrhagic stroke. Moreover, in stroke patients, atherosclerotic plaques were observed more frequently in patients with FS. Another study proposed that FS could predict ischemic cerebrovascular events while patients with classical cardiovascular risk factors had FS at a higher frequency.

4 | CONCLUSIONS

Classical risk factors for coronary artery disease should be assessed in every patient. The presence of one or multiple risk factors should raise the suspicion of coronary artery
disease, especially in symptomatic patients. We propose that the assessment of classical risk factors and the presence of FS should be part of the routine cardiovascular clinical examination.

AUTHOR CONTRIBUTIONS
George Bazoukis: Management of the patient, wrote the first draft, major revision, approval of the final manuscript. Stamatis S Papadatos: literature review, major revision, approval of the final manuscript. Dimitrios Varrias: literature review, major revision, approval of the final manuscript. Gary Tse: literature review, major revision, approval of the final manuscript.
