Abstract
In this paper we deal with the problem of determining perfectly insulating regions (cavities) from boundary measurements in a nonlinear elliptic equation arising from cardiac electrophysiology. With minimal regularity assumptions on the cavities, we first show well-posedness of the direct problem and then prove uniqueness for the inverse problem.

Keywords: cardiac electrophysiology, nonlinear elliptic equation, well-posedness, inverse problem, uniqueness

1. Introduction
In this paper we analyze a mathematical model arising from applications in cardiac electrophysiology. The goal is to collect boundary data and a mathematical description of the electrical activity of the heart in order to detect ischemic regions, characterized by having conductivity properties different from the ones in the surrounding healthy tissue [12].

In [3], the stationary version of the monodomain model describing the electrical activity of the heart was investigated leading to the study of a Neumann problem for a semilinear elliptic equation. Ischemic regions were modeled as conductivity inhomogeneities of small size and with low conductivity compared to the surrounding medium. The presence of the inhomogeneity alters the electrical activity generating a perturbation in the transmembrane potential described in terms of an asymptotic expansion in the smallness parameter which contains information on the size and shape of the altered region. Based on the aforementioned
results a topological gradient method was implemented in [4] for the effective reconstruction of the inhomogeneities from boundary measurements of the potential.

In [5] the authors analyzed the mathematical model in the case of inhomogeneities of arbitrary shape and size in the two-dimensional setting. In particular, the issue of reconstruction of the inhomogeneity from boundary measurements was addressed. It is well known that this is a highly nonlinear and severely ill-posed inverse problem. Indeed, even for its linear counterpart, the inverse conductivity problem, uniqueness might be guaranteed only if infinitely many measurements of solutions are available and even with smoothness a priori information on the unknown inclusion, the continuous dependence from the data is logarithmic.

It has been observed that, after myocardial infarction, and completed healing process, lethal ventricular ischemic tachycardia can appear. This is due to the presence of the infarct scar, a non-excitatory tissue (mainly composed of collagen), that can be modeled as an electrical insulator [9–11]. The determination of these regions and their shape is then fundamental to perform successful radiofrequency ablation for the prevention of tachycardia.

Mathematically, this leads to model the damaged regions as perfect insulators, i.e. as cavities. In this case, the inverse problem is expected to be more treatable. In fact, in the linear conductivity equation one boundary measurement is enough to recover in a stable way smooth cavities, cf [1].

We start with analyzing the well-posedness of the direct boundary value problem under minimal regularity assumptions on the cavities. Notably, we establish a uniqueness result for the inverse problem showing that a single boundary measurement of the potential is enough to detect a finite collection of separated simply connected Lipschitz cavities. More precisely, we consider the following boundary value problem

\[
\begin{align*}
 -\text{div}(A(x)\nabla u) + u^3 &= f, \quad \text{in } \Omega \setminus D \subset \mathbb{R}^2 \\
 \frac{\partial A u}{\partial n} &= 0, \quad \text{on } \partial(\Omega \setminus D),
\end{align*}
\] (1.1)

where, in the application we have in mind, \(A(x)\) is the anisotropic conductivity tensor in the heart tissue, \(\frac{\partial A u}{\partial n}\) is the current flux, \(D \subset \Omega\) denotes the ischemic region. Finally, \(f\) is a given instantaneous current applied to the heart tissue, usually in a confined region and expressing the initial electrical stimulus and \(u = u(D)\) the transmembrane potential.

We first show well-posedness of (1.1) in a variational setting in \(H^1(\Omega \setminus D)\), where \(\Omega \setminus D\) has Lipschitz boundary, together with some crucial a priori \(L^\infty\) bounds for the solutions that we derive using the truncation method of Stampacchia. Subsequently, by exploiting similar bounds for a suitable sequence of approximating problems, we prove the well-posedness of the direct problem in \(H^1(\Omega \setminus D)\), with \(\Omega \setminus D\) belonging to a special class of finite perimeter sets. We point out that in non-Lipschitz domains Sobolev embeddings and extension properties do not hold and therefore cannot be used to prove existence and uniqueness of the (weak) solution. The sequence of approximating problems is precisely defined in order to avoid this drawback. Moreover, the extension to this general class of cavities, allows us to treat the case of cavities \(D\) touching the boundary \(\partial \Omega\), since in that case \(\Omega \setminus D\) may not be Lipschitz even if \(\Omega\) and \(D\) are smooth.

Then we deal with the inverse problem of determining cavities \(D\) from measurements of the solution \(u = u(D)\) of (1.1) on some open arc \(\Sigma\) of \(\partial \Omega\). Here, we need to assume the cavities \(D\) to have Lipschitz boundary. Using uniform \(L^\infty(\Omega)\) estimates for solutions of (1.1) and unique continuation properties for elliptic equations [2], we prove that one measurement of \(u\) on \(\Sigma\) is
enough to uniquely determine a cavity $D$. We expect to extend the uniqueness for the inverse problem in the three-dimensional setting in a forthcoming publication.

Let us finally point out that recently there has been growing interest towards inverse boundary value problems for semilinear elliptic equations, see for example [15–19]. In particular, we would like to mention [15], where the authors use the nonlinear Dirichlet to Neumann map to recover simultaneously the nonlinear term appearing in the equation and the cavity. Here, instead, the nonlinearity is given and a collection of separated cavities have to be identified and in fact only one measurement suffices to determine them. Also, we would like to emphasize that our results could be easily extended to the case where the conormal derivative of $u$ on part of $\partial \Omega$ is different from zero and more general nonlinearities are considered.

The paper is organized as follows: in section 2 we state our main assumptions. In section 3 we analyze the well-posedness of problem (2.1) when $\Omega \setminus D$ is a Lipschitz domain. In section 4 we extend it to the case when $D$ belongs to a special class of sets of finite perimeter and finally in section 5 we prove the uniqueness of the inverse problem in the class of Lipschitz cavities.

2. Notation and main assumptions

We consider the following inhomogeneous Neumann problem for a semilinear equation

$$
\begin{aligned}
-\text{div}(A(x)\nabla u) + u^3 &= f, & & \text{in } \Omega \setminus D \\
\frac{\partial^3 u}{\partial n} &= 0, & & \text{on } \partial(\Omega \setminus D).
\end{aligned}
$$

(2.1)

where we denote by $\frac{\partial^3 u}{\partial n}$ the conormal derivative of $u$ defined as $A(x)\nabla u \cdot n$, with $n$ outer unit normal to $\Omega_D$. In what follows we will use the notation

$$\Omega_D = \Omega \setminus D$$

Let us now state our main assumptions.

**Assumption 1.** $\Omega \subset \mathbb{R}^2$ is a bounded domain with Lipschitz boundary, $\partial \Omega$.

**Assumption 2.** $\Sigma \subset \partial \Omega$ is an open arc, the portion of boundary which is accessible for measurement and $\Omega_1 \subset \Omega$ is such that $\partial \Omega_1$ is Lipschitz and $\Sigma \subset \partial \Omega_1 \cap \partial \Omega$ (figure 1).

**Assumption 3.** $D \in \mathcal{D}$ defined by

$$\mathcal{D} = \{D = \bigcup_{j=1}^{N} D_j \subset \overline{\Omega} : D_j \text{ compact, simply connected, int}(D_j) \neq \emptyset, \text{ dist}(D_j, \overline{\Omega}) > 0, \forall j = 1, \ldots, N \}$$

Notice that we do not exclude the case that $\partial \Omega \cap \partial D \neq \emptyset$. Finally, on the equation parameters we assume

**Assumption 4.** $A(x)$ is a symmetric matrix of order 2 satisfying the boundedness and ellipticity conditions

$$0 < \lambda \|\xi\|^2 \leq \sum_{i,j=1}^{2} a_{ij}(x)\xi_i\xi_j \leq \Lambda \|\xi\|^2, \quad \forall \xi = (\xi_1, \xi_2) \in \mathbb{R}^2$$

(2.2)
where $\lambda, \Lambda$ are positive constants.

Assumptions on the source term $f$ will be specified in the sequel when necessary.

3. The direct problem—well posedness when $\Omega_D$ has Lipschitz boundary

3.1. Existence and uniqueness of the weak solution

We will first show that problem (2.1) (in weak form) is well posed under the additional assumption that $\Omega_D$ has Lipschitz boundary. In this case, the result holds for general sources $f \in H^1(\Omega_D)'$, the dual space of $H^1(\Omega_D)$.

**Theorem 3.1.** Assume that $\Omega_D$ has Lipschitz boundary and that $f \in H^1(\Omega_D)'$. Then problem (2.1) has a unique solution $u \in H^1(\Omega_D)$.

**Proof.** By multiplying the equation in (2.1) by a test function $\phi$, integrating by parts and using the Neumann boundary condition, we obtain the weak formulation

$$
\int_{\Omega_D} (A(x)\nabla u) \cdot \nabla \phi + \int_{\Omega_D} u^3 \phi = \int_{\Omega_D} f \phi, \quad \forall \phi \in H^1(\Omega_D). \quad (3.1)
$$

Now let $T: H^1(\Omega_D) \to H^1(\Omega_D)'$ be the operator defined by

$$
\langle Tu, \phi \rangle = \int_{\Omega_D} (A(x)\nabla u) \cdot \nabla \phi + \int_{\Omega_D} u^3 \phi, \quad \forall \phi \in H^1(\Omega_D)
$$

It is readily verified that $T$ is a potential operator, that is $Tu - f$ is the derivative of the functional

$$
E(u) = \frac{1}{2} \int_{\Omega_D} (A(x)\nabla u) \cdot \nabla u + \frac{1}{4} \int_{\Omega_D} u^4 - \int_{\Omega_D} fu \quad (3.2)
$$

Figure 1. Example of domain with cavities.
Then, the theorem will follow by showing that $T$ is bounded, strictly monotone and coercive; in fact, by these properties of $T$ the functional $E$ is coercive and weakly lower semicontinuous on $H^1(\Omega_D)$ (see e.g. [13], theorem 26.11). Thus, $E$ is bounded from below and attains its infimum at some $u \in H^1(\Omega_D)$ satisfying $Tu = f$. The uniqueness of $u$ is a consequence of the strict monotonicity of $T$; for, if $Tu = Tv = f$, equation (3.3) below implies $u = v$.

(a) $T$ is bounded.

By Hölder’s inequality and ellipticity condition (2.2)

$$|\langle Tu, \phi \rangle| \leq \Lambda \|\nabla u\|_{L^2(\Omega_D)} \|\nabla \phi\|_{L^2(\Omega_D)} + \|u\|_{L^3(\Omega_D)}^3 \|\phi\|_{L^2(\Omega_D)}$$

and by Sobolev embedding theorem $\|u\|_{L^3(\Omega_D)} \leq C_5 \|u\|_{H^1(\Omega_D)}$, so that

$$|\langle Tu, \phi \rangle| \leq \Lambda \|\nabla u\|_{L^2(\Omega_D)} \|\nabla \phi\|_{L^2(\Omega_D)} + C_5^3 \|u\|_{H^1(\Omega_D)}^3 \|\phi\|_{L^2(\Omega_D)}$$

$$\leq \max \left[ \Lambda \|u\|_{H^1(\Omega_D)}, C_5^3 \|u\|_{H^1(\Omega_D)}^3 \right] \|\phi\|_{H^1(\Omega_D)}.$$ 

Therefore, if $u$ belongs to a bounded subset of $H^1(\Omega_D)$,

$$\|Tu\|_{H(\Omega_D)^\prime} = \sup_{\phi} \left| \langle Tu, \phi \rangle \right| \leq \max \left[ \Lambda \|u\|_{H^1(\Omega_D)}, C_5^3 \|u\|_{H^1(\Omega_D)}^3 \right] = C_2.$$ 

(b) $T$ is (strictly) monotone.

$$\langle Tu - Tv, u - v \rangle = \int_{\Omega_D} (A(x) \nabla (u - v)) \cdot \nabla (u - v)$$

$$+ \int_{\Omega_D} (u - v)^2 (u^2 + uv + v^2) \geq 0.$$ 

Furthermore

$$\langle Tu - Tv, u - v \rangle = 0 \iff u = v.$$ 

(3.3)

(c) $T$ is coercive, that is

$$\lim_{\|u\|_{H^1(\Omega_D)}^{-+} \to +\infty} \frac{\langle Tu, u \rangle}{\|u\|_{H^1(\Omega_D)}} = +\infty$$ 

(3.4)

By using again Hölder’s inequality,

$$\langle Tu, u \rangle \geq \lambda \int_{\Omega_D} |\nabla u|^2 + \int_{\Omega_D} u^4$$

$$\geq \lambda \|\nabla u\|_{L^2(\Omega_D)}^2 + \frac{1}{\|\Omega_D\|} \left( \int_{\Omega_D} u^2 \right)^2$$

$$\geq \lambda \|\nabla u\|_{L^2(\Omega_D)}^2 + \frac{1}{\|\Omega_D\|} \|u\|_{L^2(\Omega_D)}^4$$

$$= \lambda \left( \|\nabla u\|_{L^2(\Omega_D)}^2 + \|u\|_{L^2(\Omega_D)}^2 \right) + \frac{1}{\|\Omega_D\|} \|u\|_{L^2(\Omega_D)}^4 - \lambda \|u\|_{L^2(\Omega_D)}^2.$$
Finally, by \(|\Omega_D|^{-1}x^4 - \lambda x^2 \geq -\lambda^2 |\Omega_D|/4\), we get
\[
\langle Tu, u \rangle \geq \lambda \|u\|_{H^1(\Omega_D)}^2 - \frac{\lambda^2}{4} |\Omega_D| \tag{3.5}
\]
hence, (3.4) follows.

\begin{remark}

It is worthwhile to stress that theorem 3.1 also holds when the conormal derivative of \(u\) is different from zero on \(\partial \Omega_D\). Actually, in this case the right-hand side in (3.1) can be written as \(\langle f, \phi \rangle = \int_{\Omega_D} f \phi + \int_{\Gamma} g \phi |_{\partial \Omega_D}\), with \(f_0 \in L^2(\Omega_D)\), \(g \in L^2(\partial \Omega_D)\).
\end{remark}

\begin{remark}

One can easily check that the above proof can be extended when \(\Omega_D \subset \mathbb{R}^3\), as the Sobolev embedding \(\|u\|_{L^6(\Omega_D)} \leq C \|u\|_{H^3(\Omega_D)}\) still holds.
\end{remark}

3.2. A priori bounds for the solution

In this section we will prove estimates of the solutions to problem (2.1) which will be useful in the subsequent discussion. To begin with, we have the following stability estimate:

\begin{proposition}

Let \(u \in H^1(\Omega_D)\) be a solution of (2.1). Then
\[
\|u\|_{H^1(\Omega_D)} \leq \frac{1}{\lambda} \|f\|_{H^{1/2}} + |\Omega_D|^{1/3} \|f\|_{H^{1/2}} \leq C(\|f\|_{H^{1/2}} + \|f\|_{H^{1/2}}) \tag{3.6}
\]
where the constant \(C = \max \{\lambda, |\Omega_D|^{1/3}\} \) and \((H^1)^* = H^1(\Omega_D)^*\).
\end{proposition}

\begin{proof}

Letting \(\phi = u\) in equation (3.1) and by the ellipticity condition (2.2), we readily get
\[
\lambda \|\nabla u\|_{L^2(\Omega_D)}^2 + \int_{\Omega_D} u^4 \leq \|f\|_{H^{1/2}} \|u\|_{H^1(\Omega_D)}. \tag{3.7}
\]
By the above inequality we first obtain
\[
\|\nabla u\|_{L^2(\Omega_D)}^2 \leq \frac{\|f\|_{H^{1/2}}}{\lambda} \|u\|_{H^1(\Omega_D)}.
\]
Furthermore, by the inequality
\[
\|u\|_{L^2(\Omega_D)}^4 \leq |\Omega_D| \int_{\Omega_D} u^4
\]
and again by (3.7) we get
\[
\|u\|_{L^2(\Omega_D)}^2 \leq \left( |\Omega_D| \|f\|_{H^{1/2}} \|u\|_{H^1(\Omega_D)} \right)^{1/2}.
\]
Then
\[
\|u\|_{H^1(\Omega_D)}^2 \leq \frac{1}{\lambda} \|f\|_{H^{1/2}} \|u\|_{H^1(\Omega_D)} + \left( |\Omega_D| \|f\|_{H^{1/2}} \right)^{1/2} \|u\|_{H^1(\Omega_D)}^{1/2} \tag{3.8}
\]
We can rewrite the above estimate in the form
\[
\|u\|_{H^1}^{1/2} \left( \|u\|_{H^1} - \frac{1}{\lambda} \|f\|_{H^{1/2}} \right) \leq |\Omega_D|^{1/2} \|f\|_{H^{1/2}}^{1/2}.
\]
Now, either
\[ \|u\|_{H^1(\Omega_D)} \leq \frac{1}{\lambda} \|f\|_{H^{1/2}'} \]
or
\[ \left( \|u\|_{H^1} - \frac{1}{\lambda} \|f\|_{H^{1/2}'} \right)^{3/2} \leq |\Omega_D|^{1/2} \|f\|_{H^{1/2}'}^{1/2}. \]
In both cases (3.6) holds. □

Another crucial bound for the solution follows by the maximum principle, with some additional assumption on the source \( f \).

**Theorem 3.5.** Let \( u \in H^1(\Omega_D) \) be a solution of (2.1) with \( f \in L^2(\Omega_D) \). Then
\[
\left( \text{ess inf } f \right)^{1/3} \leq u(x) \leq \left( \text{ess sup } f \right)^{1/3} \text{ a.e. } x \in \Omega_D. \tag{3.9}
\]

**Proof.** We will use a truncation method due to Stampacchia (see [6]). Consider a function \( G : \mathbb{R} \to \mathbb{R} \) such that
\[
\begin{align*}
G(t) & \geq 0 \\
G(t) &= 0 \text{ for } t \leq 0 \\
0 & < G' \leq \gamma \text{ for } t > 0.
\end{align*}
\]
For some \( \alpha \in \mathbb{R} \) consider \( G(u - \alpha) \); because of the above definition \( G(u - \alpha) \) belongs to \( H^1(\Omega_D) \) for every \( \alpha \) and therefore can be taken as test function in (3.1) to get
\[
\int_{\Omega_D} G'(u - \alpha)(A(x) \nabla u) \cdot \nabla u + \int_{\Omega_D} u^3 G(u - \alpha) = \int_{\Omega_D} f G(u - \alpha); \tag{3.10}
\]
subtracting \( \int_{\Omega_D} u^3 G(u - \alpha) \) from both sides we obtain
\[
\int_{\Omega_D} G'(u - \alpha)(A(x) \nabla u) \cdot \nabla u + \int_{\Omega_D} (u^3 - \alpha^3) G(u - \alpha) = \int_{\Omega_D} (f - \alpha^3) G(u - \alpha). \tag{3.11}
\]
Now observe that the first integral on the left-hand side of (3.11) is \( \geq 0 \) because of the definition of \( G \) and the ellipticity condition; if we now choose \( \alpha = \left( \sup_{\Omega_D} f \right)^{1/3} \) the right-hand side is \( \leq 0 \). Hence,
\[
\int_{\Omega_D} (u^3 - \alpha^3) G(u - \alpha) = \int_{\Omega_D} (u - \alpha) G(u - \alpha)(u^2 + \alpha u + \alpha^2) \leq 0.
\]
Since \( tG(t) \geq 0 \) \( \forall t \in \mathbb{R} \) and also \( u^2 + \alpha u + \alpha^2 \geq 0 \) the above inequality implies \( (u - \alpha) G(u - \alpha) = 0 \) a.e. and therefore \( u \leq \alpha = \left( \sup_{\Omega_D} f \right)^{1/3} \) a.e., which is the right-hand side inequality in (3.9). For the left-hand side inequality apply the same argument to \( -u \). □

**Remark 3.6.** Observe that in the proof of estimates (3.6) and (3.9) we did not use any regularity of the set \( \Omega_D \).
4. The direct problem—well posedness when $\partial D$ has finite Hausdorff measure

We now generalize the well-posedness of the direct problem to the more general class of cavities $D \in \mathcal{D}$ satisfying
\begin{equation}
\mathcal{H}(\partial D) < \infty
\tag{4.1}
\end{equation}
where $\mathcal{H}$ denotes the one dimensional Hausdorff measure, $\partial D$ the topological boundary of $D$.

To this aim, we need some additional assumptions on the source term $f$ in problem (2.1):

**Assumption 5.**

\[ f \in L^\infty(\Omega), \quad f \geq 0, \quad \text{supp}(f) \subset \Omega_1, \]  
\tag{4.2}
where $\Omega_1$ is defined in the assumption 2.

As we will see in the next section, these assumptions are also convenient in investigating uniqueness of the inverse problem.

We recall that (measurable) subsets whose boundary satisfies (4.1) are in particular subsets of **finite perimeter** in $\mathbb{R}^2$ (see e.g. [14] chapter 5). Moreover, by approximation results in geometric measure theory (see e.g. [7, 8]), for every $D \in \mathcal{D}$ satisfying (4.1) there exists a sequence of Lipschitz (in fact, smooth) domains $\Omega_k$ such that $\Omega_1 \subset \Omega_k \subset \Omega_D$ and
\begin{equation}
\lim_{k \to \infty} |\Omega_D \setminus \Omega_k| = 0.
\tag{4.3}
\end{equation}

For any $k \in \mathbb{N}$, let us now consider the perturbed problem
\begin{equation}
\int_{\Omega_D} (A(x) \nabla v) \cdot \nabla \phi + \int_{\Omega_D \setminus \Omega_k} v \phi + \int_{\Omega_k} v^3 \phi = \int_{\Omega_D} f \phi
\tag{4.4}
\end{equation}
i.e. with a non-linearity of the form
\[ v \mapsto v \chi_{\Omega_D \setminus \Omega_k} + v^3 \chi_{\Omega_k}, \]
where $\chi_E$ denotes the indicator function of a set $E$.

The corresponding nonlinear operator (still denoted by $T$) defined by the left-hand side of (4.4) i.e.
\begin{equation}
\langle T v, \phi \rangle = \int_{\Omega_D} (A(x) \nabla v) \cdot \nabla \phi + \int_{\Omega_D \setminus \Omega_k} v \phi + \int_{\Omega_k} v^3 \phi
\tag{4.5}
\end{equation}
is well defined in $H^1(\Omega_D)$ since the nonlinear term can still be bounded by Sobolev embedding theorem (the boundary of $\Omega_k$ is Lipschitz). Moreover, $T$ is a potential operator being the derivative of
\begin{equation}
E(v) = \frac{1}{2} \int_{\Omega_D} (A(x) \nabla v) \cdot \nabla v + \frac{1}{2} \int_{\Omega_D \setminus \Omega_k} v^2 + \frac{1}{4} \int_{\Omega_k} v^4 - \int_{\Omega_D} f v
\tag{4.6}
\end{equation}

Then, following the proof of theorem 3.1 we can still show (see appendix A) that $T$ is **bounded, strictly monotone and coercive**. It follows that problem (4.4) has a unique solution $v_k \in H^1(\Omega_D)$ for every $k$.  

8
Moreover, it turns out that estimates in the previous section also hold for the \( v_k \)’s; note that, in establishing the bound (4.8) below, we now exploit the positivity and the localization of the source \( f \).

**Lemma 4.1.** Let \( v_k \in H^1(\Omega_D) \) be a solution to (4.4). Then,

\[
\|v_k\|_{H^1(\Omega_D)} \leq \frac{1}{\lambda} \|f\|_{H^1(\Omega_D)} + |\Omega_D|^{1/3} \|f\|_{H^1(\Omega_D)}^{1/3}.
\]  

(4.7)

Furthermore, if \( f \) satisfies assumption \( S \)

\[
0 \leq v_k(x) \leq \left( \text{ess sup}_{\Omega_D} f \right)^{1/3} \quad \text{a.e. } x \in \Omega_D.
\]  

(4.8)

**Proof.** Letting \( \phi = v_k \) in (4.4) and by the ellipticity condition, we get

\[
\lambda \|\nabla v_k\|_{L^2(\Omega)}^2 + \int_{\Omega \setminus \Omega_k} v_k^2 + \int_{\Omega_k} v_k^4 \leq \|f\|_{H^1(\Omega_D)}^2 \|v_k\|_{H^1(\Omega_D)}.
\]  

(4.9)

In particular

\[
\|\nabla v_k\|_{L^2(\Omega)}^2 + \|v_k\|_{L^2(\Omega \setminus \Omega_k)}^2 \leq \frac{\|f\|_{H^1(\Omega_D)}^2 \|v_k\|_{H^1(\Omega)}}{\lambda} \|v_k\|_{H^1(\Omega)}
\]

and

\[
\|v_k\|_{L^2(\Omega_k)}^2 \leq \left( |\Omega_D| \|f\|_{H^1(\Omega_D)}^2 \|v_k\|_{H^1(\Omega_D)} \right)^{1/2}.
\]

Summing up the two estimates term by term we get again

\[
\|v_k\|_{H^1(\Omega_D)}^2 \leq \frac{1}{\lambda} \|f\|_{H^1(\Omega_D)}^2 \|v_k\|_{H^1(\Omega_D)} + \left( |\Omega_D| \|f\|_{H^1(\Omega_D)} \right)^{1/2} \|v_k\|_{H^1(\Omega_D)}^{1/2}
\]

and the bound (4.7) is proven by the same argument following (3.8).

Let us now take \( f \in L^2(\Omega_D) \) satisfying assumption \( S \) and consider a function \( G \) as in the proof of theorem 3.5. Then, choose \( \phi = G(v_k - \alpha) \) in (4.4), where \( \alpha \geq 0 \) and get

\[
\int_{\Omega_D} G'(v_k - \alpha)(A(x)\nabla v_k) \cdot \nabla v_k + \int_{\Omega \setminus \Omega_k} v_k G(v_k - \alpha) + \int_{\Omega_k} v_k^3 G(v_k - \alpha) = \int_{\Omega_k} f G(v_k - \alpha).
\]

Subtracting on both sides the term \( \int_{\Omega_k} \alpha^3 G(v_k - \alpha) \), we obtain the equivalent equation

\[
\int_{\Omega_D} G'(v_k - \alpha)(A(x)\nabla v_k) \cdot \nabla v_k + \int_{\Omega_D} \left[ (v_k - \alpha) \chi_{\Omega_D \setminus \Omega_k} + (v_k^3 - \alpha^3) \chi_{\Omega_k} \right] G(v_k - \alpha)
\]

\[
= \int_{\Omega_k} (f - \alpha^3) G(v_k - \alpha) - \alpha \int_{\Omega_k} G(v_k - \alpha).
\]  

(4.10)

By choosing \( \alpha = \left( \text{sup}_{\Omega_D} f \right)^{1/3} \geq 0 \), the right-hand side is \( \leq 0 \). Hence,

\[
\int_{\Omega_D} \left[ (v_k - \alpha) \chi_{\Omega_D \setminus \Omega_k} + (v_k^3 - \alpha^3) \chi_{\Omega_k} \right] G(v_k - \alpha)
\]

\[
= \int_{\Omega_D} (v_k - \alpha) \left[ \chi_{\Omega_D \setminus \Omega_k} + (v_k^2 + v_k \alpha + \alpha^2) \chi_{\Omega_k} \right] G(v_k - \alpha) \leq 0.
\]
Problem 5.1. Assume it is possible to measure the solution to (2.1), \( u|_\Sigma \) where \( \Sigma \) is an open connected portion of \( \partial \Omega_1 \cap \partial \Omega \). Is it possible to uniquely determine \( D \)?

The answer is yes assuming the coefficient matrix \( A \) has constant entries.

Theorem 5.2. Let assumptions 1–5 hold, a constant matrix and \( D_1, D_2 \) in \( \mathcal{D} \) where \( D_1 = \bigcup_{j=1}^M D^j_1 \) and \( D_2 = \bigcup_{j=1}^M D^j_2 \) and assume \( D_1, D_2 \) with Lipschitz boundary.

Let \( u_1 \) and \( u_2 \) be the corresponding solutions to the boundary value problem (2.1).

Then \( u_1|_\Sigma = u_2|_\Sigma \) implies \( D_1 \equiv D_2 \) (which in particular implies \( N = M \)).
Proof. Without loss of generality we will prove the result for the Laplacian. Assume first that the cavities are strictly contained in \( \Omega \). Let \( u_1 = u_2 \) on \( \Sigma \); we will prove the theorem through an argument by contradiction. Assume \( D_1 \neq D_2 \) then setting \( w := u_1 - u_2 \) we have that
\[
   w|_{\Sigma} = 0 \quad \text{and} \quad \nabla w \cdot \nu|_{\Sigma} = 0
\]
(5.1)
Moreover \( w \) is a solution to
\[
   -\Delta w + q(x)w = 0 \quad \text{in } \Omega \setminus (D_1 \cup D_2)
\]
(5.2)
where \( q(x) = u_1^2 + u_1 u_2 + u_2^2 \). By (3.9) we have
\[
   \|q\|_{L^\infty(\Omega \setminus (D_1 \cup D_2))} \leq C,
\]
with \( C \) a constant depending on \( \|f\|_{L^\infty(\Omega D)} \). Uniqueness for the Cauchy problem together with the weak unique continuation property (see for example [2]) implies
\[
   w \equiv 0 \quad \text{in } G
\]
(5.3)
where \( G \) is the connected component of \( \Omega \setminus D_1 \cup D_2 \) that contains \( \Sigma \). Let \( \tilde{G} = \Omega \setminus G \) and observe that: \( \tilde{G} \) is closed, \( \tilde{G} \supseteq D_1 \cup D_2 \) and
\[
   \partial \tilde{G} = (\partial D_1 \cup \partial D_2) \cap \partial G.
\]
(5.4)
Let \( \tilde{D} \) be a connected component of \( \tilde{G} \setminus D_2 \) (note that \( \tilde{D} = D_1 \) if \( D_1 \cap D_2 = \emptyset \)). Then we have
\[
   \partial \tilde{D} \subseteq \partial \left( \tilde{G} \setminus D_2 \right) \subseteq \partial \tilde{G} \cup \partial D_2.
\]
(5.5)
We further note that, unless \( D_1 \subset D_2 \), we may assume that \( \tilde{D} \) contains a subset of \( D_1 \) with nonempty interior. Otherwise, we just exchange the roles of \( D_1 \) and \( D_2 \).

Let us now define \( \Gamma_1 \equiv \partial \tilde{D} \cap \partial D_1 \cap \partial \tilde{G} \) and let \( \partial \tilde{D} = \Gamma_1 \cup \Gamma_2 \). Observe that (5.4) implies that \( \Gamma_1 \subset \partial D_1 \cap \partial \tilde{G} \) and from (5.5) \( \Gamma_2 \equiv \partial \tilde{D} \setminus \Gamma_1 \subset \partial D_2 \) including possibly the case where \( \Gamma_2 = \emptyset \). In figures 2 and 3 the shaded regions show examples of possible geometries.

- Assume first that \( \tilde{D} \) is Lipschitz. Observe that on \( \partial \tilde{D} \) we have \( \partial u_1 \over \partial n = 0 \) a.e.. Actually, on \( \Gamma_1 \) we have \( \partial u_1 \over \partial n = 0 \) a.e. and observing that on \( \Gamma_1 \subset \partial G \) \( \partial u_1 \over \partial n = \partial u_2 \over \partial n \) a.e., it follows that \( \partial u_2 \over \partial n = 0 \) a.e. on \( \Gamma_1 \). Moreover, on \( \Gamma_2 \) we have that \( \partial u_2 \over \partial n = 0 \) a.e.

Also, \( u_2 \in H^1(\tilde{D}) \) is solution of
\[
   -\Delta u_2 + u_2^3 = 0 \quad \text{in } \tilde{D}
\]
(5.6)
since \( \tilde{D} \cap \Omega_1 = \emptyset \). Hence, multiplying the equation by \( u_2 \) and integrating by parts over the set \( \tilde{D} \), we have
\[
   \int_{\tilde{D}} \nabla u_2 \cdot \nabla u_2 + u_2^4 = 0,
\]
(5.7)
which implies that necessarily \( u_2 = 0 \) a.e. in \( \tilde{D} \) and, by unique continuation, also in \( G \setminus \text{supp } f \). Now, let \( K \subset G \) and \( K \supset \text{supp } f \) be a smooth domain. Then letting \( v_2 = u_2^3 \).
\( u_2 \) satisfies
\[
\begin{cases}
-\Delta u_2 + v_2 u_2 = f, & \text{in } K \\
\frac{\partial u_2}{\partial n} = 0, & \text{on } \partial K \\
u_2 = 0, & \text{on } \partial K,
\end{cases}
\quad (5.8)
\]

Consider \( \psi \), any solution of the Schrödinger equation
\[
-\Delta \psi + v_2 \psi = 0, \quad \text{in } K; \quad (5.9)
\]
we will show that \( \int_K f \psi = 0 \).

To see this multiply equation in (5.8) by \( \psi \), integrate twice by parts and use conditions on \( u_2 \) in (5.8)
\[
\int_K f \psi = \int_K [-\Delta u_2 \psi + v_2 u_2 \psi] = -\int_{\partial K} \frac{\partial u_2}{\partial n} \psi + \int_K [\nabla u_2 \cdot \nabla \psi + v_2 u_2 \psi] \\
= \int_{\partial K} u_2 \frac{\partial \psi}{\partial n} + \int_K [-\Delta \psi u_2 + v_2 u_2 \psi] = \int_K u_2 [-\Delta \psi + v_2 \psi] = 0.
\]
\quad (5.10)

Now choose \( \psi \) such that \( \psi|_{\partial K} = \alpha < 0 \); then maximum principle implies that \( \psi < 0 \) in \( K \) and from \( \int_K f \psi = 0 \) with \( f \geq 0 \); we conclude that \( f \equiv 0 \) in \( K \) which contradicts the initial hypotheses.

* Now consider the case where \( \tilde{D} \) is not Lipschitz. Observe that singularities on \( \partial \tilde{D} \) can only occur at points of intersection between \( \Gamma_1 \) and \( \Gamma_2 \). Let us name them \( P^h, h = 1, \ldots, L \). Note that singularities can only be cusps since \( \Gamma_1 \) and \( \Gamma_2 \) are Lipschitz. We will now construct an approximation of \( \tilde{D} \) with a sequence of Lipschitz domains, \( \{ \tilde{D}_k \} \subset \tilde{D} \). For each \( P^j \) take two sequences \( \{ P^h_k \} \subset \Gamma_1 \) and \( \{ Q^h_k \} \subset \Gamma_2 \) such that both the arcs \( P^h_k \) and \( Q^h_k \) have length which tends to zero as \( k \to +\infty \). For each \( h = 1, \ldots, L \) let \( \gamma^h_k \) be smooth arcs joining \( P^h_k \) and \( Q^h_k \), so that the region \( \tilde{D}_k \) enclosed by the \( \gamma^h_k \)'s and \( \Gamma_1 \) and \( \Gamma_2 \) is Lipschitz. Moreover assume that \( \text{length}(\gamma^h_k) \to 0 \) and \( |\tilde{D} \setminus \tilde{D}_k| \to 0 \) as \( k \to +\infty \).

Again by assumption 5, \( u_2 \in H^1(\tilde{D}_k) \) is a weak solution of
\[
-\Delta u_2 + u_2^3 = 0 \quad \text{in } \tilde{D}_k
\]
\quad (5.11)
with \( \frac{\partial u_2}{\partial n} = 0 \) a.e. on \( \partial \tilde{D}_k \setminus \left( \bigcup_{h=1}^L \gamma^h_k \right) \). Hence, multiplying equation (5.11) by \( u_2 \), integrating by parts over \( \tilde{D}_k \) and using the fact that \( u_2 \in H^{3/2}(\Omega \setminus D_2) \), see for example [20, 21], it follows that
\[
\int_{\tilde{D}_k} \nabla u_2 \cdot \nabla u_2 + u_2^3(x) = \sum_{h=1}^L \int_{\gamma^h_k} \frac{\partial u_2}{\partial n} u_2.
\]
\quad (5.12)

Moreover, since \( \tilde{D}_k \) is a Lipschitz domain and \( u_2 \) is uniformly bounded in \( \Omega \setminus D_2 \) it follows that
Figure 2. Possible configuration: example 1.

Figure 3. Possible configuration: example 2.

\[ \left| \int_{\gamma^k} \partial u_2 \cdot \partial n \right| \leq \left( \int_{\gamma^k} |\partial u_2|^2 \right)^{1/2} \left( \int_{\gamma^k} |u_2|^2 \right)^{1/2} \leq C \|u_2\|_{H^{3/2}(\Omega_D)} (\text{length}(\gamma^k))^{1/2} \]

for \( h = 1, \ldots, L \). So, passing to the limit as \( k \to +\infty \) in (5.12) we finally get

\[ \int_{\tilde{D}} \nabla u_2 \cdot \nabla u_2 + u_2^2(x) = 0 \]

which again gives \( u_2 = 0 \) a.e. in \( \tilde{D} \) and, by unique continuation, also in \( (\Omega \setminus D_1 \cup D_2) \setminus \text{supp} \ f \).

From now on we can proceed as in the previous case and conclude the proof.

Finally, if the cavity touches the boundary of \( \Omega \) forming a cusp, it is sufficient to modify the above estimates by replacing the norm \( \|u\|_{H^{3/2}(\Omega_D)} \) with \( \|u\|_{H^{3/2}(\Omega_{\Omega_D})} \), where \( \Omega_{\Omega_D} \) is any Lipschitz subset satisfying \( \tilde{D} \subset \Omega_{\Omega_D} \subset \Omega_{D_2} \). In fact, it can be shown that the solution \( u_2 \) (which is uniquely defined in \( \Omega_{\Omega_D} \) by theorem 4.2) has the required regularity in those subsets.

\[ \square \]

Remark 5.3. Note that we use the assumption of constant coefficient matrix \( A \) only in the second part of the proof and for the case of cavities touching the boundary since we need to guarantee \( H^{3/2} \) regularity of solutions. It would be interesting to see whether it is possible to extend uniqueness to variable matrices \( A(x) \).
6. Conclusions

In this paper we analyze the inverse problem of determining insulating planar regions, cavities, from boundary measurements in a nonlinear elliptic equation which arises in cardiac electrophysiology. We first show well-posedness of the forward problem in the class of cavities with boundaries having finite one-dimensional Hausdorff measure. Then we prove unique determination of multiple Lipschitz cavities from knowledge of a single boundary measurement of the potential. This last result has been obtained using unique continuation properties of solutions to linear elliptic equations and \textit{a priori} bounds on the solution to the forward problem.

We plan to analyze also the three-dimensional case. This paper is also the starting point for the implementation of a reconstruction algorithm based on a phase field approach that will be presented in a forthcoming publication.

Although the proof of uniqueness of the solution to the inverse problem is independent on the nonlinear structure of the equation, it would be interesting to make a comparison between the reconstruction of the cavity in the nonlinear problem with the one obtained in the linear conductivity equation.

Data availability statement

Appendix A

We show that the estimates in the proof of theorem 3.1 can be repeated to show that also the operator $T$ defined by (4.5) is \textit{bounded}, \textit{strictly monotone} and \textit{coercive}.

(a) $T$ is bounded.

\[ |(Tu, \phi)| \leq \Lambda \| \nabla u \|_{L^2(\Omega_D)} \| \nabla \phi \|_{L^2(\Omega_D)} + \| u \|_{L^2(\Omega_D, \Omega_k)} \| \phi \|_{L^2(\Omega_D, \Omega_k)} + \| u \|^3_{H^1(\Omega_D)} \| \phi \|_{L^2(\Omega_k)} \]

\[ \leq \Lambda \| \nabla u \|_{L^2(\Omega_D)} \| \nabla \phi \|_{L^2(\Omega_D)} + \| u \|_{L^2(\Omega_D, \Omega_k)} \| \phi \|_{L^2(\Omega_D, \Omega_k)} + C_3 \| u \|^3_{H^1(\Omega_D)} \| \phi \|_{L^2(\Omega_k)} \]

\[ \leq \max \left[ (\Lambda + 1) \| u \|_{H^1(\Omega_D)}^4, C_3 \| u \|^3_{H^1(\Omega_D)} \right] \| \phi \|_{H^{-1}(\Omega_D^c)}. \quad (A.1) \]

Therefore, if $u$ belongs to a bounded subset of $H^1(\Omega_D)$,

\[ \| Tu \|_{(H^1(\Omega_D))^*} = \sup_{\phi} \frac{|(Tu, \phi)|}{\| \phi \|_{H^1(\Omega_D)}} \leq \max \left[ (\Lambda \| u \|_{H^1(\Omega_D)}^3, (1 + C_3) \| u \|^3_{H^1(\Omega_D)} \right] = C_4. \]

(b) $T$ is (strictly) monotone.

\[ \langle Tu - Tv, u - v \rangle = \int_{\Omega_D} (A(x) \nabla (u - v)) \cdot \nabla (u - v) + \int_{\Omega_D \setminus \Omega_k} (u - v)^2 \]

\[ + \int_{\Omega_k} (u - v)^2(u^2 + uv + v^2) \geq 0. \]
and
\[ \langle Tu - Tv, u - v \rangle = 0 \iff u = v. \] (A.2)

(c) T is coercive
\[ \langle Tu, u \rangle \geq \lambda \int_{\Omega_D} |\nabla u|^2 + \int_{\Omega_D \setminus \Omega_k} u^2 + \int_{\Omega_k} u^2 \]
\[ \geq \lambda \|\nabla u\|_{L^2(\Omega_D)}^2 + \|u\|_{L^2(\Omega_D \setminus \Omega_k)}^2 + \int_{\Omega_k} \frac{1}{|\Omega_k|} \|u\|_{L^2(\Omega_k)}^4 \]
\[ \geq \min(1, \lambda) \|u\|_{H^1(\Omega_D)}^2 + \frac{1}{|\Omega_k|} \|u\|_{L^2(\Omega_k)}^4 - \|u\|_{L^2(\Omega_k)}^2. \] (A.3)

Finally, as in the previous proof from $|\Omega_k|^{-\frac{1}{4}} x^4 - x^2 \geq -|\Omega_k|/4$, with $x = \|u\|_{L^2(\Omega_k)}$, we get
\[ \langle Tu, u \rangle \geq \tilde{\lambda} \|u\|_{H^1(\Omega_D)}^2 - \frac{1}{4} |\Omega_k|, \] (A.4)

where $\tilde{\lambda} := \min(1, \lambda)$; hence, (3.4) follows.
