The Double Copy of Massive Scalar-QCD

Jan Plefka, Canxin Shi, and Tianheng Wang

Institut für Physik und IRIS Adlershof, Humboldt-Universität zu Berlin, Zum Großen Windkanal 6, 12489 Berlin, Germany

We construct the gravitational theory emerging from the double-copy of massive scalar quantum chromodynamics in general dimensions. The resulting two-form-dilaton-gravity theory couples to flavored massive scalars gravitationally and via the dilaton. It displays scalar self-interaction terms of arbitrary even order in the fields but quadratic in derivatives. We work out the emerging Lagrangian explicitly up to the sixth order in scalar fields and propose an all order form.

I. INTRODUCTION

A most remarkable property of gravitational scattering amplitudes on Minkowski space-time backgrounds is a factorization of these highly involved structures into simpler building blocks arising from two gauge theoretical scattering amplitudes known as the Bern-Carrasco-Johansson (BCJ) double-copy relation \[1\]. The BCJ double-copy acts inherently perturbatively and reflects a fascinating duality between the gauge theoretic color and kinematical degrees of freedom of scattering amplitudes. It provides a mechanism to transform the local gauge symmetries of the double-copied Yang-Mills theory to the diffeomorphism symmetry of the resulting gravitational theory. This procedure hinges upon finding a representation of the gauge theory amplitudes built from trivalent graphs with color and kinematic numerator factors fulfilling Jacobi-like identities. It was originally observed for pure gauge theories (with and without supersymmetry) which double copied to pure (super-)gravities and has proven to be an efficient tool also beyond tree-level (where proofs of the double-copy exist \[4\]) to generate amplitude integrands at high-loop orders in the maximal supersymmetric case \[6\]. By now the double-copy has been observed in a large set of gravitational theories involving massless fields, including pure gravity \[8\], pure and matter coupled supergravities \[8-10\] as well as Einstein-Yang-Mills theories \[11-14\]. In \[15, 16\], the double copy of QCD with \( N_f \) massive spin 1/2 particles in the fundamental representation was studied following, which double copies to two-form-dilaton-gravity (a.k.a. \( N = 0 \) supergravity) coupled to massive scalars and vectors, see also \[17\] for related work. This field content of the double copied theory follows from the tensor product of the on-shell degrees of freedom

\[
[A_{\mu} \oplus (N_f \times \Psi)]^\otimes 2 = h_{\mu\nu} \oplus B_{\mu\nu} \oplus \phi \oplus (N_f \times \phi).
\]

The resulting gravitational Lagrangian is not obvious at all in the matter sector and contains contact terms of pure scalar and vector-scalar type to all orders. The explicit form up to quartic order was worked out in detail in \[16\].

In this work we extend these results by going down in spin and work out the details of the double copy of massive scalar QCD. In this setup the resulting field content is two-form-dilaton-gravity coupled to \( N_f \) massive scalars, i.e.

\[
[A_{\mu} \oplus (N_f \times \phi)]^\otimes 2 = h_{\mu\nu} \oplus B_{\mu\nu} \oplus \phi \oplus (N_f \times \phi).
\]

We have constructed the emerging gravitational Lagrangian up to sixth order in the scalar contact terms and moreover propose a general structure. We also show that there are no two-form-scalar couplings, i.e. axion-scalar couplings in 4d, as is commonly expected. Partial results along these lines up to quartic order in scalar couplings appeared recently in \[17\] as this work was close to completion.

Next to clarifying the general structure of the double-copy construction one further motivation for this work lies the application to the classical double copy. This is particularly relevant in applications to the two-body problem in general relativity – being of central importance for gravitational wave physics. Here the goal is to use the double-copy construction to innovate state-of-the-art techniques for the computation of effective two-body potentials in the post-Newtonian and post-Minkowski expansions which is an emerging interdisciplinary field \[15-20\]. This connection comes about from an effective field theory perspective where spinless black-holes may be modeled by massive scalar particles in the classical and large mass limit (for introductory reviews see \[11\]). While the double copy procedure could be efficiently applied up to the 1PN and 2PM level \[18, 20-24\] a recent double-copy construction at the 2PN and 3PM level of the present authors and Steinhoff revealed a disagreement with the known 2PN result in dilaton-gravity \[14\].

Let us briefly review the double-copy procedure at tree-level. A general \( n \)-point amplitude in the gauge theory, here scalar QCD, takes the generic form

\[
A_n = g^{m-2} \sum_{\Gamma = 1} \frac{1}{S_\Gamma} \prod_{j=1}^{c_j n_j} D_{\alpha_j}
\]

where \( \Gamma \) is the set of relevant trivalent graphs and \( g \) the coupling. The \( D_\alpha \) denote the inverse propagators and \( S_\Gamma \) is the symmetry factor of the graph. Note that via the trivial identity \( 1 = D_\alpha / D_{\alpha_j} \) any graph in a Feynman

---

1 See \[3\] for a recent comprehensive review.
diagrammatic expansion can be made trivalent formally. The central criterion is that in the above representation of the amplitude the numerators of color $c_i$ and kinematics $n_i$ obey identical algebraic relations

$$c_s + c_t = c_u \quad n_s + n_t = n_u \quad \text{(4)}$$

emerging from the Jacobi identity for the $c_i$. The doublecopied amplitude is then obtained by simply replacing $c_i \rightarrow n_i$ in (3), a process known as ‘squaring’.

II. SCALAR-QCD AMPLITUDES

The scalar-QCD Lagrangian with the scalar fields in the fundamental representation reads

$$\mathcal{L}_{\text{QCD}} = -\frac{1}{4} F_{\mu\nu}^a F^{\mu\nu,a} - \frac{1}{2}(\partial^\mu A_\mu^a)^2 + \sum_\alpha \left( (D_\mu \varphi_{\alpha,i}) D^{\mu} \varphi_{\alpha,i} - m^2_\alpha \varphi_{\alpha,i}^\dagger \varphi_{\alpha,i} \right), \quad \text{(5)}$$

where $\alpha = 1, 2, \cdots , N_f$ labels the flavor of the massive scalar fields and $i$ denotes the color index. We note that there are no contact interactions of massive scalar fields in this Lagrangian. The conventions and the Feynman rules following from (5) are given in Appendix A.

From the Feynman rules, the 3-point amplitude of two massive scalars and one gluon can be read off immediately,

$$A(1_{\alpha,j}, \overline{2}_{\alpha,i}, \overline{3}^a) = i \frac{g}{\sqrt{2}} T^a_{ij} \epsilon_{3} \cdot (p_1 - p_2), \quad \text{(6)}$$

where the massive scalar particle and antiparticle are indicated by the under- and over-lines respectively, $p_i$ denotes the external momentum of particle $i$ and all external momenta are incoming.

The scattering amplitude of two gluons and two massive scalars reads

$$A(1_{\alpha,j}, \overline{2}_{\alpha,i}, 3^a, 4^b) = \left( T^a T^b \right)_{ij} n_u + \left( T^b T^a \right)_{ij} n_s + \frac{f^{abc} T^c_{ij} n_s}{s_{34}}. \quad \text{(7)}$$

Note that we use $s_{i,j} \equiv (p_i + \cdots + p_j)^2$ throughout this paper. The kinematic numerators are given by

$$n_u = i g^2 \left[ 2(\epsilon_4 \cdot p_1)(\epsilon_3 \cdot p_2) + (\epsilon_3 \cdot \epsilon_4)(p_1 \cdot p_4) \right] \quad \text{(8)}$$

$$n_s = i g^2 \left[ 2(\epsilon_3 \cdot p_1)(\epsilon_4 \cdot p_2) + (\epsilon_3 \cdot \epsilon_4)(p_1 \cdot p_3) \right] \quad \text{(9)}$$

$$n_u = i g^2 \left[ 2(\epsilon_4 \cdot p_1)(\epsilon_3 \cdot p_2) - 2(\epsilon_3 \cdot p_1)(\epsilon_4 \cdot p_2) + (\epsilon_3 \cdot \epsilon_4)(p_1 \cdot (p_4 - p_3)) \right]. \quad \text{(10)}$$

We notice that the color and the kinematic numerators above automatically satisfy the relations below

$$(T^a T^b)_{ij} - (T^b T^a)_{ij} = f^{abc} T^c_{ij}, \quad \text{(11)}$$

$$n_u - n_t = n_s. \quad \text{(12)}$$

FIG. 1: Topologies of Feynman diagrams of the 6-scalar amplitude. Curly lines denotes possible massless propagators.

Hence, the kinematic numerators are in the BCJ-respecting representation and are ready to be squared in the double copy construction.

The 4-scalar amplitudes can also be straightforwardly obtained. When the two pairs of scalars are of the same flavor (mass), the amplitude reads

$$A(1_{\alpha,j}, \overline{2}_{\alpha,i}, 3^a, 4^b) = T^a_{ij} T^b_{ik} i g^2 (p_3 \cdot (p_1 - p_2)) + T^b_{ik} T^a_{ij} i g^2 (p_3 \cdot (p_1 - p_2)) \quad \text{(13)}$$

When the two scalar pairs are of different flavors (masses), the amplitude reads

$$A(1_{\alpha,j}, \overline{2}_{\alpha,i}, 3^a, 4^b) = T^a_{ij} T^b_{ik} i g^2 (p_3 \cdot (p_1 - p_2)). \quad \text{(14)}$$

In these 4-scalar amplitudes, there are not enough color structures to form Jacobi identities.

The simplest 6-scalar amplitude is the one with three scalar pairs of distinct flavors (masses). The three topologies of the diagrams that contribute to this amplitude are given in the left column of figure II and the amplitude reads

$$A(1_{\alpha,j}, \overline{2}_{\alpha,i}, 3^a, 4^b) = \left( \begin{array}{c} c_0 n_0 \\ s_{12} s_{34} s_{56} \\ (s_{134} - m_a^2) s_{34} s_{56} \\ (s_{156} - m_b^2) s_{34} s_{56} \\ \text{(cyclic)} \end{array} \right) \quad \text{(15)}$$

where the color factors read

$$c_0 = T^a_{ij} T_{kl} \epsilon_{mn} T^{abc}, \quad \text{(16)}$$

$$c_1 = T^a_{mn} T^b_{kl} \epsilon_{mn} T^{abc},$$

$$c_2 = T^a_{mn} T^b_{kl} \epsilon_{mn} T^{abc}.$$

The other numerators are gained from cyclic rotations of the labels $(1, 2) \rightarrow (3, 4) \rightarrow (5, 6)$ in $n_1$ and $n_2$. The explicit expressions for the kinematic numerators are given
We note that the color factors and the kinematic numerators satisfy the same relation below
\begin{equation}
    c_1 - c_2 = c_0, \quad n_1 - n_2 = n_0.
\end{equation}

For the cases where the flavors are not all distinguished, more diagrams and the symmetry factors associated with the diagrams need to be taken care of. In the end, the BCJ-respecting numerators are likewise constructed.

### III. DOUBLE COPY

It is well-known that the double copy of YM field gives a graviton, a two-form field (B-field), and a dilaton. Their associated polarization tensors are identified with the tensor products of the gluon polarization vectors in the following ways,

- **graviton**: \(( \epsilon^h )_{ij} = \epsilon^{(i,v)}_{\mu} \epsilon^{(j,v)}_{\nu} \),
- **B-field**: \(( \epsilon^B )_{ij} = \epsilon^{[i,v]}_{\mu} \epsilon^{[j,v]}_{\nu} \),
- **dilaton**: \(( \epsilon^\phi )_{\mu\nu} = \frac{ \epsilon^{\mu}_{\nu} \epsilon^{\nu}_{\mu} \delta_{ij}}{\sqrt{D-2}} \),

where the double parenthesis denotes taking the symmetric-traceless part of the tensor product. Note that the superscripts \( i,j \) are not related to the color group as in \([3]\), but are the little group indices. The dilaton identification can be further simplified as
\begin{equation}
    (\epsilon^\phi)_{\mu\nu}(p,q) = \frac{1}{\sqrt{D-2}} \left( -\eta_{\mu\nu} + \frac{p_{\mu} q_{\nu} + p_{\nu} q_{\mu}}{p \cdot q} \right),
\end{equation}

where \( p \) is the momentum associated to the external particle, and \( q \) is an arbitrary reference null-vector.

With this double-copy prescription, we can now get the gravitational amplitudes from the corresponding YM ones. We focus on the scattering processes that involve at least one pair of massive scalars. We present all the relevant double copy results up to 4-point as well as the 6-scalar amplitude in this chapter. The simplest case on the YM side is the 3-point amplitude with two scalars and one gluon. Its double copy gives two different amplitudes,
\begin{align}
    M(1, 3, 4_h) &= i \kappa^2 (\epsilon^h)^{i\mu} p^\mu_{1} p^\nu_{2}, \\
    M(1, 3, 4_\phi) &= \frac{i \kappa m^2}{\sqrt{D-2}}.
\end{align}

Note that the amplitude vanishes when the massless particle is the B-field due to the anti-symmetrization. This applies to any amplitude that involves an odd number of B-fields, so we will only write down the non-vanishing ones. Similarly, the 4-point amplitude of two massive scalars and two gluon \([7]\) gives the following gravitational amplitudes after the double copy,
\begin{align}
    M(1, 3, 2_\phi, 4_h) &= i \kappa^2 (\epsilon^h)^{i\mu} p^\mu_{1} p^\nu_{2} \left[ \frac{1}{s_{34}} \left( s_{13} p^\mu_{1} p^\nu_{2} \eta^{\mu\nu} + s_{14} p^\mu_{1} p^\nu_{2} \eta^{\mu\nu} - p^\mu_{1} p^\mu_{2} p^\nu_{1} p^\nu_{2} - p^\mu_{1} p^\mu_{2} p^\nu_{2} p^\nu_{1} + 2 p^\mu_{1} p^\mu_{2} p^\mu_{2} p^\nu_{1} \right) \right], \\
    M(1, 3, 2_\phi, 4_\phi) &= \frac{i \kappa^2 m^2 (\epsilon^h)^{i\mu} p^\mu_{1} p^\nu_{2} \left[ \frac{1}{s_{34}} \left( p^\nu_{1} p^\mu_{2} p^\mu_{2} p^\nu_{1} + \frac{m^2}{s_{14} - m^2} + \frac{m^2}{s_{13} - m^2} \right) \right], \\
    M(1, 3, 2_B, 4_B) &= \frac{i \kappa^2 (\epsilon^B)^{i\mu} p^\mu_{1} p^\nu_{2} \left( 2 p^\nu_{1} p^\mu_{2} p^\nu_{1} - 2 (p_{1} \cdot p_{3}) p^\mu_{1} p^\nu_{2} \eta^{\mu\nu} - (p_{1} \cdot p_{3}) (p_{1} \cdot p_{4}) \eta^{\mu\nu} \right). \\
    M(1, 3, 2_\phi, 4_\phi) &= \frac{i \kappa^2 (\epsilon^\phi)^{i\mu} p^\mu_{1} p^\nu_{2} \left[ \frac{1}{s_{34}} \left( s_{23} + s_{34} \right) \right] \\
    M(1, 3, 2_\phi, 4_\phi) &= -i \kappa^2 \left( \frac{s_{34}}{16} - \frac{p_{1} \cdot p_{3} p_{2} \cdot p_{3} - p_{1} \cdot p_{3} p_{2} \cdot p_{4}}{s_{23}} \right), \\
    M(1, 3, 2_\phi, 4_\phi) &= -i \kappa^2 \left( \frac{s_{34}}{16} - \frac{p_{1} \cdot p_{3} p_{2} \cdot p_{3}}{s_{23}} \right).
\end{align}

The 6-scalar amplitude is also directly gained from \([10]\), though the result is too lengthy to fit in this article. These amplitudes will be exploited to extract the higher-order terms of the Lagrangian.

### IV. TWO-FORM-DILATON-GRAVITY WITH MASSIVE SCALARS

The Lagrangian of the two-form-dilaton-gravity reads
\begin{equation}
    \mathcal{L}_{adg} = \sqrt{-g} \left[ -\frac{2}{\kappa^2} R + \frac{D - 2}{2} g^{\mu\nu} \partial_\mu \phi \partial_\nu \phi + \frac{1}{6} e^{-2\kappa \phi} H_{\lambda\mu\nu} H^{\lambda\mu\nu} \right].
\end{equation}

The interactions involving massive scalars may now be extracted from the amplitudes computed above. In fact, we found that the minimal coupling of massive scalars and gravity reproduces the 2-massive-1-graviton amplitude \([20]\) and the 2-massive-2-graviton amplitude \([22]\).
It is straightforward to extend to higher points,
\[ \mathcal{L}_{\text{matter}} = \sqrt{-g} \sum_{\alpha} (g^{\mu\nu} \partial_\mu \varphi^\dagger_\alpha \partial_\nu \varphi_\alpha - m^2_{\alpha} \varphi^\dagger_\alpha \varphi_\alpha). \] (29)

Adopting de Donder gauge, we write down the relevant 
\[ \mathcal{L}_{\text{DC}} = \mathcal{L}_{\text{adj}} + \sqrt{-g} \left[ g^{\mu\nu} \partial_\mu \varphi^\dagger_\alpha \partial_\nu \varphi_\alpha - m^2_{\alpha} e^{-\kappa \phi} \varphi^\dagger_\alpha \varphi_\alpha + \left( \frac{\kappa^2}{32} \varphi^\dagger_\alpha \varphi_\alpha - \frac{\kappa^4}{512} (\varphi^\dagger_\alpha \varphi_\alpha)^2 \right) D_\mu D^\mu (\varphi^\dagger_\alpha \varphi_\alpha) \right], \] (30)

where \( D_\mu \) is the covariant derivative and flavor indices 
that appear twice in a term are summed over implicitly. It 
is also known that the dilaton appears as an exponent 
when coupled to other fields. Let us now explain the 
extraction of each contact term in (30). We first make 
an ansatz on how the dilaton couples to massive scalars,
\[ \mathcal{L}_{\varphi^\dagger_\alpha \varphi} = \sqrt{-g} \left( e^{\lambda \phi} g^{\mu\nu} \partial_\mu \varphi^\dagger_\alpha \partial_\nu \varphi_\alpha - m^2_{\alpha} e^{\kappa \phi} \varphi^\dagger_\alpha \varphi_\alpha \right) \], (31)

whose leading term in \( \kappa \) gives the canonical kinetic and 
mass terms. We can compute the 3-point amplitude 
of two matter fields and a dilaton,
\[ \mathcal{M}(1, \bar{\Sigma}, 3_\beta) = i(\lambda - \zeta) \kappa m^2 \sqrt{D - 2}. \] (32)

Matching to the double copy result \cite{21}, we have \( \lambda - \zeta = 1 \). The 2-massive-2-dilaton amplitude from double copy 
\cite{24} subtracted by all Feynman diagrams that contain 
only cubic vertices yields the diagram that comes from 
the contact term,

\[ \mathcal{M}(1, \bar{\Sigma}, 3_\beta) = -i \kappa^2 \frac{2}{2} \left( m^2 (1 + 2 \lambda - 2 \lambda^2) + \frac{\lambda^2}{4} s_{34} \right). \] (33)

We can also calculate this diagram directly from Feyn- 
man rules of the 4-point contact term,
\[ \mathcal{M}(1, \bar{\Sigma}, 3_\beta) = -i \kappa^2 \frac{2}{2} \left( m^2 (\zeta^2 - \lambda^2) + \frac{\lambda^2}{2} s_{34} \right). \] (34)

Comparing the above formulae, \cite{33} and \cite{34}, we have 
two equations of \( \lambda \) and \( \zeta \). Together with \( \lambda - \zeta = 1 \), we 
fnd the solution,
\[ \lambda = 0, \quad \zeta = -1. \] (35)

We also verified that \cite{31} gives the correct 4-point 
\ amplitude of 2 massive scalars, 1 dilaton and 1 graviton, of \cite{23}. As for the 2 massive scalar and 2 B-field scattering, 
we compute the amplitude from the perturbative Lagrangian \cite{30}. It coincides with \cite{25}, so there is no 
direct coupling of the B-field and massive scalars at least 
at 3- and 4-point levels.

We can get the interaction terms up to quadratic order in \( \kappa \). The 6-scalar amplitude gives us the 6-scalar contact term. In the end, we find the following Lagrangian from the double copy

\[ \mathcal{L}_{\varphi^\dagger_\alpha \varphi} = \sqrt{-g} \left( \frac{\kappa^2}{32} \varphi^\dagger_\alpha \varphi_\alpha D_\mu D^\mu (\varphi^\dagger_\alpha \varphi_\alpha) \right), \] (40)

The 6-scalar contact term is computed in the same way. For simplicity, the 3 pairs of scalars are taken to be of 
different flavors. Cases where two or three pairs of scalar 
are of the same flavor can be gained by simply exchanging 
the external particles. We match the amplitude computed 
from summing all Feynman diagrams to the double
Note that in 4D upon dualizing the two-form to an axion with shift $D$ do look somewhat non-standard with the double derivatives. We now have calculated every term in (30). The corresponding interaction will be

$$L_{\varphi^6} = -\sqrt{-g} \frac{k^4}{512} \left( \varphi^\dagger_\alpha \varphi_\alpha \right)^2 D\mu D\nu \left( \varphi^\dagger_\beta \varphi_\beta \right).$$  

(42)

We now have calculated every term in (30).

V. FIELD REDEFINITIONS AND A RESUMMED ACTION

The established higher order terms in the action (30) do look somewhat non-standard with the double derivatives $D\mu D\nu$, appearing. We would now like to unify them with the kinetic and mass term in (30) by performing a suitable field redefinition.[2] To this end we consider the shift

$$\varphi_\alpha \rightarrow \varphi_\alpha + \frac{k^2}{32} \varphi_\alpha (\varphi^\dagger_\beta \varphi_\beta) + \frac{k^4}{1024} \varphi_\alpha (\varphi^\dagger_\beta \varphi_\beta)^2$$  

(43)

that transforms the matter part of the Lagrangian (30) into

$$L_{DC\text{matter}} = \sqrt{-g} \left[ g^{\mu\nu} \partial_\mu \varphi^\dagger_\alpha \partial_\nu \varphi_\alpha - m^2 e^{-\kappa \phi} \varphi^\dagger_\alpha \varphi_\alpha \right] \times \left[ 1 + \frac{k^2}{16} (\varphi^\dagger_\beta \varphi_\beta) + \frac{3k^4}{1024} (\varphi^\dagger_\beta \varphi_\beta)^2 + O(\kappa^6) \right].$$  

(44)

By the S-matrix equivalence theorem this action after the field redefinitions and the previous one (30) have identical scattering amplitudes,\[3] This form of the action suggests itself to an attractive resummation into the compact form

$$L_{DC} = L_{\text{adg}} + \sqrt{-g} \frac{\partial_\mu \varphi^\dagger_\alpha \partial^\mu \varphi_\alpha - m^2 e^{-\kappa \phi} \varphi^\dagger_\alpha \varphi_\alpha}{1 - \frac{\kappa^2}{32} (\varphi^\dagger_\beta \varphi_\beta)^2},$$  

(45)

with $L_{\text{adg}}$ the two-form-dilaton-gravity theory of (28). Note that in 4D upon dualizing the two-form to an axion $\chi$ the axio-dilaton system displays a striking similarity to the massive flavored scalar Lagrangian above. In 4D the double copy of scalar QCD takes the form

$$L_{(sQCD)^2} = -\frac{2\sqrt{-g}}{\kappa^2} R + \sqrt{-g} \frac{\partial_\mu Z \partial^\mu Z}{\left( 1 - \frac{\kappa^2}{32} (Z \partial Z)^2 \right)} + \frac{\sqrt{-g}}{\kappa} \frac{\partial_\mu \varphi^\dagger_\alpha \partial^\mu \varphi_\alpha - m^2 e^{-\kappa \phi} \varphi^\dagger_\alpha \varphi_\alpha}{\left( 1 - \frac{\kappa^2}{32} (\varphi^\dagger_\beta \varphi_\beta)^2 \right)^2}.$$

(46)

Here the complex scalar field $Z$ is built from the dilaton and axion as

$$Z = \frac{\kappa (e^{-\kappa \phi} - 1)}{\kappa \kappa (e^{-\kappa \phi} + 1)}$$  

(47)

and enjoys an SL(2, $\mathbb{R}$) symmetry (see e.g. [45]). We note in closing that such a symmetry is also present in the scalar sector for the $N_f = 1$ and massless case.

VI. CONCLUSIONS

In this letter we explicitly constructed the double copy of scalar QCD in arbitrary dimensions resulting in an extension of the established two-form-dilaton gravity model ("$\mathcal{N} = 0$ supergravity") by interacting massive flavored scalars displaying self interactions to arbitrary field orders. We found no coupling of the flavored scalars to the two-form, i.e. axion in 4d, as is commonly expected, yet not proven. Moreover, we saw that the self-interaction terms are always quadratic in derivatives. We constructed the emerging Lagrangian explicitly up to sixth order in fields. It would be important to develop a deeper understanding as to what symmetry controls the form of these self-interactions at all orders. It should be an extension of the still elusive kinematic algebra. We expect these results to be of value in the future for using the double-copy formalism in the two-body problem in classical General Relativity which should emerge from the infinite mass limit of the theory we have constructed. Yet it appears to us that the established novel contact terms will not alter the classical limit of the two massive scalar scatterings and cannot account for the discrepancies observed in [44].

ACKNOWLEDGMENTS

We wish to thank Alexander Ochirov for illuminating discussions leading to the resummed form of the scalar action. Appendix A: Feynman Rules

The covariant derivative and the field strength tensor in (30) read
\[ D_\mu \varphi_{\alpha,i} = \partial_\mu \varphi_{\alpha,i} - i \frac{g}{\sqrt{2}} T^a_i \varphi_{\alpha,i}, \quad (A1) \]
\[ F^a_{\mu\nu} = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu - i \frac{g}{\sqrt{2}} f^{abc} A^b_\mu A^c_\nu. \quad (A2) \]

The generators of the gauge group are normalized such that
\[ [T^a, T^b]_{ij} = f^{abc} T^c_{ij}, \quad (A3) \]
\[ \text{Tr}(T^a T^b) = \delta^{ab}. \quad (A4) \]

The Lagrangian (30) gives canonically normalized propagators and interaction vertices involving only gluons. The couplings of massive scalars with gluons read
\[ a, \mu \quad \rightarrow (p_1 - p_2) \mu, \quad (A5) \]
\[ a, \mu \quad \rightarrow i \frac{g^2}{2} (T^a_{ik} T^b_{kj} + T^b_{ik} T^a_{kj}) \eta^{i\mu}. \quad (A6) \]

As for the gravitational theory (30), we adopt the de Donder gauge, where the propagators are
\[ \mu, \nu \quad \rightarrow \frac{i}{p^2} \left( \eta^{(\rho, \psi)\nu} - \frac{1}{D - 2} \eta^{(\mu, \nu)\rho} \right), \quad (A7) \]
\[ \mu, \nu \quad \rightarrow \frac{i}{(D - 2)p^2}. \quad (A8) \]

Since the kinetic term of dilaton is non-canonical, we dress each external dilaton by a factor $1/\sqrt{D - 2}$. The propagator of B-field is not needed in this paper. The Feynman rules of massive scalars coupled to graviton and dilaton are respectively
\[ \mu, \nu \quad \rightarrow -i \kappa \left( \frac{\eta^{(\mu, \nu)}_\rho (p_1 \cdot p_2 + m^2) - \eta^{(\mu, \nu)}_\rho (p_1 \cdot p_2)}{2} \right), \quad (A9) \]
\[ \mu, \nu \quad \rightarrow i \kappa m^2. \quad (A10) \]

The kinematic numerators in (15) are
\[ n_0 = \frac{ig^4}{4} \left( p_1 - p_2 \right)_\mu \left( p_3 - p_4 \right)_\nu \left( p_5 - p_6 \right)_\rho, \quad (A15) \]
\[ V_{1+2+3+4+5+6}^{\mu\nu\rho} \quad (A16) \]
\[ n_1 = -ig^4 \left[ p_1 \cdot (p_5 - p_6) p_2 \cdot (p_3 - p_4) \right. \]
\[ + \frac{1}{4} (s_{134} - m_d^2) (p_3 - p_4) \cdot (p_5 - p_6) \] \[ n_2 = -ig^4 \left[ p_1 \cdot (p_3 - p_4) p_2 \cdot (p_5 - p_6) \right. \]
\[ + \frac{1}{4} (s_{156} - m_d^2) (p_3 - p_4) \cdot (p_5 - p_6) \] \[ n_3 \quad (A17) \]
\[ n_4 \quad (A18) \]

where
\[ V_{1+2}^{\mu\nu\rho} = \eta^{(\rho, \nu)} (p - q)^\rho + \text{cyclic}. \]

The other numerators are gained from cyclic rotations of the labels $(1, 2) \rightarrow (3, 4) \rightarrow (5, 6)$ in $n_1$ and $n_2$.
