Abstract

We present Buchberger Theory and Algorithm of Gröbner bases for multivariate Ore extensions of rings presented as modules over a principal ideal domain. The algorithms are based on Möller Lifting Theorem.

In her 1978 Bachelor’s thesis [54] Zacharias discussed how to extend Buchberger Theory [7, 8, 10] from the case of polynomial rings over a field to that of polynomials over a Noetherian ring with suitable effectiveness conditions.

In the meantime a similar task was performed in a series of papers — Kandri-Rody–Kapur [21] merged the rewriting rules behind Euclidean Algorithm with Buchberger’s rewriting, proposing a Buchberger Theory for polynomial rings over Euclidean domains; Pan [40] studied Buchberger Theory for polynomial rings over domains introducing the notions of strong/weak Gröbner bases — which culminated with [35].

Such unsurpassed paper, reformulating and improving Zacharias’ intuition, gave efficient solutions to compute both weak and strong Gröbner bases for polynomial rings over each Zacharias ring, with particular attention to the PIR case. Its main contribution is the reformulation of Buchberger test/completion (“a basis $F$ is Gröbner if and only if each S-polynomial between two elements of $F$ reduces to 0”) in the more flexible lifting theorem (“a basis $F$ is Gröbner if and only if each element in a minimal basis of the syzygies among the leading monomials lifts, via Buchberger reduction, to a syzygy among the elements of $F$”). The only further contribution to this ultimate paper is the survey [6] of Möller’s results which reformulated them in terms of Szekeres Theory [51].

The suggestion of extending Buchberger Theory to non-commutative rings which satisfy Poincaré-Birkhoff-Witt Theorem was put forward by Bergman [5], effectively applied by Apel–Lassner [3, 4] to Lie algebras and further extended to solvable polynomial rings [22, 23], skew polynomial rings [16, 17, 18] and to other algebras [1, 11, 26, 27] which satisfy Poincaré-Birkhoff-Witt Theorem and thus, under the standard interpretation of Buchberger Theory in terms of filtration/graduations [2, 30, 33, 50, 29, 12], have the classical polynomial ring as associated graded rings.
In particular Weispfenning [53] adapted his results to a generalization of the Ore extension [39] proposed by Tamari [52]; then Weispfenning’s construction was generalized by his student Pesch [41, 42], introducing the notion of iterative Ore extension with commuting variables

\[ R := R[Y_1; \alpha_1, \delta_1][Y_2; \alpha_2, \delta_2] \cdots [Y_n; \alpha_n, \delta_n], \ R \text{ a domain;} \]

the concept has been called Ore algebra in [13] and is renamed here as multivariate Ore extension (for a different and promising approach to Ore algebras see [24]).

Bergman’s approach and most of all extensions are formulated for rings which are vector spaces over a field; in our knowledge the only instances in which the coefficient ring \( R \) is presented as a \( D \)-module over a domain \( D \) (or at least as a \( Z \)-module) are Pritchard’s [43, 44] extension of Möller Lifting Theory to non-commutative free algebras and Reinert’s [45, 46] deep study of Buchberger Theory on Function Rings.

Following the recent survey on Buchberger-Zacharias Theory for monoid rings \( R[S] \) over a unitary effective ring \( R \) and an effective monoid \( S \) [32], we propose here a Möller–Pritchard lifting theorem presentation of Buchberger-Zacharias Theory and related Gröbner basis computation algorithms for multivariate Ore extensions. The twist w.r.t. [32] is that there \( R[S] \) coincides with its associated graded ring; here \( R \), its associated graded ring

\[ G(\mathfrak{R}) := R[Y_1; \alpha_1][Y_2; \alpha_2] \cdots [Y_n; \alpha_n] \]

and the commutative polynomial ring \( R[Y_1, \ldots, Y_n] \) coincide as sets and as left \( R \)-modules, but, as rings, they have different multiplications.

We begin by recalling Ore’s original theory [39] of non-commutative polynomials \( R[Y] \), relaxing the original assumption that \( R \) is a field to the case in which \( R \) is a domain (Section 1.1) and Pesch’s constructions of multivariate Ore extensions (Section 1.2) and graded multivariate Ore extensions (Section 1.3), focusing on the arithmetics of the main Example 14

\[ \mathfrak{R} := R[Y_1; \alpha_1][Y_2; \alpha_2] \cdots [Y_n; \alpha_n], R := \mathbb{Z}[x] \quad \alpha_i(x) := c_i x^{e_i}, c_i \in \mathbb{Z} \setminus \{ 0 \}, e_i \in \mathbb{N} \setminus \{ 0 \}. \]

Next, we introduce Buchberger Theory in multivariate Ore extensions recalling the notion of term-orderings (Section 2.1), definition and main properties of left, right, bilateral and restricted Gröbner bases (Section 2.2) and Buchberger Algorithm for computing canonical forms in the case in which \( R \) is a skew field (Section 2.3).

We adapt to our setting Szekeres Theory [51] (Section 3), Zacharias canonical representation with related algorithm (Section 4) and Möller Lifting Theorem (Section 5).

The next Sections are the algorithmic core of the paper: we reformulate for multivariate Ore extensions over a Zacharias ring \( R \)

- Möller’s algorithm for computing the required Gebauer–Möller set (id est the minimal basis of the module of the syzygies among the leading monomials) for Buchberger test/completion of left weak bases (Section 6.1);

- Möller’s reformulation, requiring only l.c.m. computation in \( R \) for the case in which \( R \) is a (Zacharias) PID (Section 6.2) or a (Zacharias) PIR (Section A).
– still in the case in which $R$ is a PID (Section 6.3) or a PIR (Section A), Möller’s completion of a left weak basis to a left strong one;

– Gebauer–Möller criteria [19] for producing a Gebauer–Möller set (Section 6.4);

– Kandri-Rody–Weispfenning completion [22] of a left weak basis for producing a bilateral one (Section 7.1);

– Weispfenning’s [53] restricted completion (Section 7.2);

– as a technical tool required by Weispfenning’s restricted completion, how to produce right Gebauer–Möller sets (Section 7.3).

Finally, we reverse to a theoretical survey summarizing the structural theorem for the case in which $R$ is a Zacharias PID (Section 8), specializing to our setting Spear’s Theorem [49, 29] (Section 9) and extending to it Lazard’s Structural Theorem [25] (Section 10).

In an appendix we discuss, as far as it is possible, how to extend this theory and algorithms to the case in which $R$ is a PIR (Section A).

1 Recalls on Ore Theory

1.1 Ore Extensions

Let $R$ be a not necessarily commutative domain; Ore [39] investigated under which conditions the (left) $R$-module $R := R[Y]$ of all the formal polynomials is made a ring under the assumption that the multiplication of polynomials shall be associative and both-sided distributive and the limitation imposed by the postulate that the degree of a product shall be equal to the sum of the degree of the factors.

It is clear that, due to the distributive property, given two “monomials” $bY^r, aY^s \in R, a, b \in R$, it suffices to define the product $bY^r \cdot aY^s \in R$ or even more specifically, to define the product $Y \cdot r, r \in R$; this necessarily requires the existence of maps $\alpha, \delta : R \rightarrow R$ such that

$$Y \cdot r = \alpha(r)Y + \delta(r)\text{ for each } r \in R;$$

Ore calls $\alpha(r)$ the conjugate and $\delta(r)$ the derivative of $r$.

Under the required postulate clearly we have

1. for each $r \in R$, $\alpha(r) = 0 \implies r = 0,$

so that $\alpha$ is injective.

It is moreover sufficient to consider, for each $r, r' \in R$, the relations

$$\alpha(r + r')Y + \delta(r + r') = Y \cdot (r + r') = Y \cdot r + Y \cdot r' = (\alpha(r) + \alpha(r'))Y + \delta(r) + \delta(r'),$$

$$\alpha(rr')Y + \delta(rr') = Y \cdot (rr') = (Y \cdot r) \cdot r' = \alpha(r)\alpha(r')Y + \alpha(r)\delta(r') + \delta(r)r',$$

and, if $R$ is a skew field, and $r \neq 0$,

$$Y = (Y \cdot r) \cdot r^{-1} = \alpha(r)\alpha(r^{-1})Y + \alpha(r)\delta(r^{-1}) + \delta(r)r^{-1},$$

to deduce that
2. $\alpha$ is a ring endomorphism;

3. the following conditions are equivalent:

   (a) for each $d \in R \setminus \{0\}$ exists $c \in R \setminus \{0\}: Y \cdot c = dY + \delta(c)$, $\alpha(c) = d$;
   (b) $\alpha$ is a ring automorphism;

4. $\delta$ is an $\alpha$-derivation of $R$ id est an additive map satisfying

\[ \delta(rr') = \alpha(r)\delta(r') + \delta(r)r' \text{ for each } r, r' \in R; \]

5. if $R$ is a skew field, then each $r \in R \setminus \{0\}$ satisfies

\[ \alpha(r^{-1}) = (\alpha(r))^{-1}, \quad \delta(r^{-1}) = -(\alpha(r))^{-1}\delta(r)r^{-1}; \]

6. $\text{Im}(\alpha) \subset R$ is a subring, which is an isomorphic copy of $R$;

7. $R_1 := \{r \in R : r = \alpha(r)\} \subset R$ is a ring, the invariant ring of $R$;

8. $R_0 := \{r \in R : \delta(r) = 0\} \subset R$ is a ring, the constant ring of $R$;

9. \(\{r \in R : Y \cdot r = rY\} = R_0 \cap R_1.\)

10. If $R$ is a skew field, such are also $\text{Im}(\alpha)$, $R_1$ and $R_0$.

11. Denoting $Z := \{z \in R : rz = zr \text{ for each } r \in R\}$ the center of $R$, we have

\[ \{r \in R : f \cdot r = rf \text{ for each } f \in R\} = R_0 \cap R_1 \cap Z. \]

Moreover, if we consider two polynomials $f(Y), g(Y) \in R \setminus \{0\}$,

\[ f = aY^m + f_0, \quad g = bY^n + g_0, \quad a, b \in R \setminus \{0\}, m, n \in \mathbb{N}, f_0, g_0 \in R, \deg(f_0) < m, \deg(g_0) < n, \]

we have

\[ f \cdot g = aa^m(b)Y^{m+n} + h(Y), \quad \deg(h) < m + n; \]

since $\alpha$ is injective, $b \neq 0 \implies \alpha(b) \neq 0 \implies \alpha^m(b) \neq 0$ and since $R$ is a domain it holds $aa^m(b) \neq a \implies aa^m(b) \neq 0 \implies f \cdot g \neq 0$. As a consequence

12. $R$ is a domain.

**Definition 1.** $R$ with the ring structure described by conditions 1, 2, 4 above is called an Ore extension and is denoted $R[Y; \alpha, \delta]$.

**Remark 2 (Ore).** In an Ore extension $R[Y; \alpha, \delta]$, denoting $\mathcal{S} = \langle \alpha, \delta \rangle$ the free semigroup over the alphabet $\{\alpha, \delta\}$ and, for each $d \in \mathbb{N}$ and $i \in \mathbb{N}, 0 \leq i \leq d$, $S_{d,i}$ the set of the $\binom{d}{i}$ words in $\mathcal{S}$ of length $d$ in which occur $i$ instances of $\alpha$ and $d - i$ instances of $\delta$ in an arbitrary order, we have

\[ Y^d \cdot r = \sum_{i=0}^{d} \sum_{\tau \in S_{d,i}} \tau(r)Y^i \]

\[ ^1\text{Whence, setting } r = r' = 1, \delta(1) = 0. \]
for each $d \in \mathbb{N}$; for instance
\[
Y^3 \cdot r = a^3(r)Y^3 + \delta^3(r) + \left(\alpha^2\delta(r) + \alpha\delta\alpha(r) + \delta\alpha^2(r)\right)Y^2 + \left(\alpha\delta^2(r) + \delta\alpha\delta(r) + \delta^2\alpha(r)\right)Y.
\]

In particular, for $f(Y) = \sum_{i=0}^{n} a_i Y^{m-i}$ and $g(Y) = \sum_{i=0}^{m} b_i Y^{m-i}$ in $R$ we have
\[
g(Y)f(Y) = \sum_{i=0}^{m+n} c_i Y^{n+m-i}
\]
with $c_0 = b_0 a^n(\alpha_0)$ and $c_i = \sum_{a=0}^{i} b_a \sum_{b=0}^{i-a} \tau(\alpha_b)$. 

Remark 3 (Ore). Under the assumption that $\alpha$ is an automorphism (cf. 3.), each polynomial $\sum_{i=1}^{n} a_i Y^i \in R$ can be uniquely represented as $\sum_{i=1}^{n} Y^i \alpha_i$ for proper values $\alpha_i \in R$.

In fact we have $ax = x\alpha^{-1}(a) - \delta(\alpha^{-1}(a))$ from which we can deduce inductively proper expressions
\[
ax^n = x^n\alpha^{-n}(a) + \sum_{i=1}^{n} (-1)^{i} x^{n-i} \sigma_{m}(a),
\]
for $\sigma_{m}(a) \in R$, properly defined (similarly to what done for $\tau \in S_{d,\alpha}$, but using the derivative and the inverse of the conjugate [39]).

\[\square\]

1.2 Multivariate Ore Extensions

Let $R$ be a not necessarily commutative domain.

Definition 4. An iterative Ore extension is a ring (whose multiplication we denote $\star$) defined as
\[
R := R[Y_1; \alpha_1, \delta_1][Y_2; \alpha_2, \delta_2] \cdots [Y_n; \alpha_n, \delta_n]
\]
where, for each $i > 1$, $\alpha_i$ is an endomorphism and $\delta_i$ an $\alpha_i$-derivation of the iterative Ore extension
\[
R_{i-1} := R[Y_1; \alpha_1, \delta_1] \cdots [Y_{i-1}; \alpha_{i-1}, \delta_{i-1}].
\]

As proved by Pesch in [41], it is possible to extend $\alpha_i$ to an endomorphism of $R$ and $\delta_i$ to an $\alpha_i$-derivation in $R$, by setting $\alpha_i(Y_j) = Y_j$ and $\delta_i(Y_j) = 0$ for each $i \leq j \leq n$.

A multivariate Ore extension (or: Ore algebra [13]; or: iterative Ore extension with commuting variables [41, 42]) is an iterative Ore extension which satisfies
- $\alpha_j \delta_i = \delta_i \alpha_j$, for each $i, j, i \neq j$,
- $\alpha_i \alpha_j = \alpha_j \alpha_i$, $\delta_i \delta_j = \delta_j \delta_i$ for $i < j \leq n$,
- $\alpha_j(Y_i) = Y_i, \delta_j(Y_i) = 0$ for $i \leq j \leq n$.

Lemma 5 (Pesch). In an iterative Ore extension, for each $i < j$ it holds
\[
Y_j \star Y_i = Y_i Y_j \iff \alpha_j(Y_i) = Y_i, \delta_j(Y_i) = 0.
\]
Proof. For each $i < j$, we have $Y_j \ast Y_i = \alpha_j(Y_i)Y_j + \delta_j(Y_i)$.

Since in this paper we are interested in iterative Ore extensions for which $Y_j \ast Y_i = Y_i Y_j$, by the previous Lemma 5, we can say that the maps $\alpha_i, \delta_i$ are relevant only on the elements of $R$, so sometimes we will restrict them to $R$.

**Lemma 6** (Pesch). An iterative Ore extension is a multivariate Ore extension iff $Y_j \ast Y_i = Y_i Y_j$ for each $i < j$.

Proof. In fact, using Lemma 5 for each $r \in R$, we have

$$
Y_j \ast Y_i \ast r = Y_j \ast (\alpha_j(r)Y_i + \delta_j(r)) = \alpha_j(\alpha_j(r)Y_i + \delta_j(r))Y_j + \delta_j(\alpha_j(r)Y_i + \delta_j(r)) = \alpha_j\alpha_j(r)Y_i Y_j + \alpha_j\delta_j(r)Y_i Y_j + \delta_j\alpha_j(r)Y_i + \delta_j\delta_j(r).
$$

and (by symmetry)

$$
Y_i Y_j \ast r = Y_i \ast (\alpha_j(r)Y_j + \delta_j(r)) = \alpha_i\alpha_i(r)Y_i Y_j + \alpha_i\delta_i(r)Y_i Y_j + \delta_i\alpha_i(r)Y_i + \delta_i\delta_i(r).
$$

Thus the $R$-module structure of a multivariate Ore extension can be identified with that of the polynomial ring $R[Y_1, \ldots, Y_n]$ over its natural $R$-basis

$$
\mathcal{T} := \{Y_1^{a_1} \cdots Y_n^{a_n} : (a_1, \ldots, a_n) \in \mathbb{N}^n\}, \quad R \equiv R[\mathcal{T}] = \text{Span}_R[\mathcal{T}].
$$

We can therefore denote $\alpha_{Y_i} := \alpha_i, \delta_{Y_i} := \delta_i$ for each $i$ and, iteratively,

$$
\alpha_{\tau Y_i} := \alpha_{\tau Y_i}, \delta_{\tau Y_i} := \delta_{\tau Y_i}, \quad \text{for each } \tau \in \mathcal{T}.
$$

Remark that a multivariate Ore extension is *not* an algebra; in fact, if we define, for $\tau = Y_1^{d_1} \cdots Y_n^{d_n}$ and $t = Y_1^{e_1} \cdots Y_n^{e_n}$ such that $\tau \mid t$

$$
\begin{pmatrix} t \\ \tau \end{pmatrix} := \begin{pmatrix} e_1 \\ d_1 \\ \vdots \\ e_n \\ d_n \end{pmatrix},
$$

we have

$$
t \ast r = \alpha_t(r)t + \sum_{\tau \mid t} \left(\begin{pmatrix} t \\ \tau \end{pmatrix}\alpha_t(r)\tau, \text{ for each } t \in \mathcal{T} \text{ and } r \in R.\right)
$$

We can define, for each $t \in \mathcal{T}$, a map

$$
\theta_t : R \rightarrow R, \quad \theta_t(r) = \sum_{\tau \mid t} \left(\begin{pmatrix} t \\ \tau \end{pmatrix}\delta_t\alpha_t(r)\tau, \text{ for each } t \in \mathcal{T} \text{ and } r \in R.\right)
$$

so that $t \ast r = \alpha_t(r)t + \theta_t(r)$ for each $t \in \mathcal{T}$ and $r \in R$.

Such maps $\alpha_t$ and $\theta_t$ satisfy properties analogous of those of Ore’s conjugate and derivative:
Lemma 7. With the present notation, for each $t \in T$, we have

1. for each $r \in R$, $\alpha_t(r) = 0 \implies r = 0$,
2. $\alpha_t$ is a ring endomorphism;
3. the following conditions are equivalent:
   (a) for each $d \in R \setminus \{0\}$ exists $c \in R \setminus \{0\}$: $Y \star c = dY + \theta_t(c), \alpha_t(c) = d$;
   (b) $\alpha_t$ is a ring automorphism;
4. $\theta_t$ is an $\alpha_t$-derivation of $R$;
5. if $R$ is a skew field, then each $r \in R \setminus \{0\}$ satisfies
   \[ \alpha_t(r^{-1}) = (\alpha_t(r))^{-1}, \quad \theta_t(r^{-1}) = - (\alpha_t(r))^{-1} \theta_t(r)r^{-1}; \]
6. $\text{Im}(\alpha_t) \subset R$ is a subring, which is an isomorphic copy of $R$.

We further have

7. if each $\alpha_i$ is an automorphism, also each $\alpha_t$, $t \in T$, is such. \hfill $\square$ 

1.3 Associated graded Ore Extension

Following the notation of 1.2 we give the following

Definition 8. A multivariate Ore extension

\[ R[Y_1; \alpha_1, \delta_1][Y_2; \alpha_2, \delta_2] \cdots [Y_n; \alpha_n, \delta_n] \]

where each $\delta_i$ is zero, will be called a graded Ore extension (or: Ore extension with zero derivations [41, 42]) and will be denoted

\[ R := R[Y_1; \alpha_1][Y_2; \alpha_2] \cdots [Y_n; \alpha_n]. \]

\hfill $\square$

Lemma 9. In a multivariate graded Ore extension,

- since it is an Ore algebra, the $\alpha$s commute,
- and $t \star r = \alpha_t(r)t$ for each $t \in T$ and $r \in R$.

Remark 10. Note that, since multivariate Ore extensions coincide, as left $R$-modules, with the classical polynomial rings $R[Y_1, \ldots, Y_n]$ and so have the same $R$-basis, namely $T^*$, they can share with the polynomial rings their standard $T$-valuation [51, 30, 2, 33] [31, §24.4,24.6]. This justifies the definition below.

Definition 11. Given an Ore extension $R := R[Y_1; \alpha_1, \delta_1][Y_2; \alpha_2, \delta_2] \cdots [Y_n; \alpha_n, \delta_n]$ the corresponding graded Ore extension $G(R) := R[Y_1; \alpha_1][Y_2; \alpha_2] \cdots [Y_n; \alpha_n]$ is called its associated graded Ore extension. \hfill $\square$
Example 12.

1. The first non-obvious example of Ore extension was proposed in 1948 by D. Tamari [52] in connection with the notion of “order of irregularity” introduced by Ore in [38]; it consists of the graded Ore extension

\[ R := R[Y; \alpha], R = \mathbb{Q}[x] \text{ where } \alpha : R \to R : x \mapsto x^2. \]

2. Such construction was generalized by Weispfenning [53] who introduced the rings

\[ R := R[Y; \alpha], R = \mathbb{Q}[x] \text{ where } \alpha : R \to R : x \mapsto x^e, e \in \mathbb{N} \]

3. and extended by Pesch [41] to his iterated Ore extensions with power substitution

\[ R := R[Y_1; \alpha_1][Y_2; \alpha_2] \cdots [Y_n; \alpha_n], R = \mathbb{Q}[x] \]

where \( \alpha_i : R \to R : x \mapsto x^{e_i}, e_i \in \mathbb{N} \).

4. An Ore extension where \( \alpha \) is invertible is discussed in [28]:

\[ R := R[S; \alpha], R = \mathbb{Q}[D_1, D_2, D_3] \]

where

\[ \alpha : R \to R : f(D_1, D_2, D_3) \mapsto f(D_2 + 2D_1, D_3, -D_1) \]

whose inverse is

\[ \alpha^{-1} : R \to R : f(D_1, D_2, D_3) \mapsto f(-D_3, D_1 + 2D_3, D_2). \]

\[ \square \]

Note that, while as \( R \)-modules \( \mathbb{R} \) and \( G(\mathbb{R}) \) coincide both with the polynomial ring \( \mathbb{P} = \mathbb{P}[Y_1, \ldots, Y_n] \), the three rings have, in general, different arithmetics; we will denote \( \ast \) the multiplication of \( \mathbb{R} \) and \( \ast \) those of \( G(\mathbb{R}) \).

Example 13. The ring of Example 12.1.

\[ R := R[Y; \alpha], R = \mathbb{Q}[x] \text{ where } \alpha : R \to R : x \mapsto x^2 \]

is an Ore extension which is graded.

Since the map

\[ \delta : \mathbb{Q}[x] \to \mathbb{Q}[x] : x^i \mapsto \sum_{h=i}^{2i-1} x^h \]

is an \( \alpha \)-derivation, \( S := R[Y; \alpha, \delta] \) is an Ore extension of which \( \mathbb{R} \) is the associated graded Ore extension.

\[ \square \]

In the following example, we define a nontrivial class of algebras, which will be used to illustrate our theory and algorithms.
Example 14. Since in Buchberger-Zacharias Theory, from an algorithmic point of view, one is interested only on the associated graded rings and thus the rôle of derivates is irrelevant, we illustrate the results for the Ore extensions with the zero-derivatives

\[ R := R[Y_1; \alpha_1][Y_2; \alpha_2] \cdots [Y_n; \alpha_n], \quad R = \mathbb{Z}[x], \]

with \( \alpha_i(x) := c_i x^{e_i}, c_i \in \mathbb{Z} \setminus \{0\}, e_i \in \mathbb{N} \setminus \{0\}. \)

If we denote \( \gamma \) the map

\[ \gamma : \mathbb{N} \times \mathbb{N} \setminus \{0\} \to \mathbb{N}, (a, e) \mapsto \sum_{i=0}^{a-1} e^i = \frac{1 - e^a}{1 - e} \]

where the last equality holds for \( e \neq 1 \), we have \( Y_i^a \ast x^b = c_i^{b(\alpha_i)} x^{e_i b} Y_i^a. \)

Note that

\[ \gamma(b, e) + e^b \gamma(a, e) = \sum_{i=0}^{b-1} e^i + \sum_{i=0}^{a-1} e^{b+i} = \sum_{i=0}^{a+b-1} e^i = \gamma(a + b, e). \]  \( \text{(1-a)} \)

Since \( \alpha_j(\alpha_i(x)) = c_i \alpha_j(x^{e_i}) = c_j c_i x^{e_i e_j} \) and \( \alpha_i(\alpha_j(x)) = c_j \alpha_i(x^{e_j}) = c_j c_i x^{e_i e_j} \), then \( R \) is a graded Ore extension if and only if

\[ c_j c_i x^{e_i e_j} = \alpha_j(\alpha_i(x)) = \alpha_i(\alpha_j(x)) = c_j c_i x^{e_j e_i} \]

id est

\[ c_j^{e_i^{-1}} = c_i^{e_j^{-1}}. \]  \( \text{(1-b)} \)

We thus have \( \binom{n}{2} \) relations among the \( n \) coefficients \( c_i \). In particular we need to partition the indices as

\[ \{1, \ldots, n\} = E \cup O \cup S, E = \{i : 2 \mid e_i\}, O = \{i : 2 \nmid e_i > 1\}, S = \{i : e_i = 1\}. \]

If \( I := O \cup E = \emptyset \) then each such equations are the trivial equality \( 1 = 1 \) and thus all \( c_i \) are free. The situation is completely different when \( I := O \cup E \neq \emptyset \); in fact,

- for \( i \in S \) necessarily \( c_i = \pm 1 \);
- if a prime \( p \) divides at least a \( c_j, j \in I \), then it divides each \( c_i, i \in I \).

As regards the sign of \( c_i \) we can say that

- if \( E \neq \emptyset \) then
  - \( c_i \) is positive for each \( i \in S \cup O \),
  - the sign of \( c_i, i \in E \), is undetermined but all the \( c_i, i \in E \), have the same sign;
- if \( E = \emptyset \) then the sign of \( c_i, i \in S \cup O \) is undetermined.

For instance
– for \( e_1 = e_4 = 1, e_2 = 5, e_3 = 3 \) we have \( S = \{1, 4\}, O = \{2, 3\}, E = \emptyset \) and
\[
\sum_{j=1}^{n} c_j = c_1^0, c_2^0 = c_2^0, c_3^0 = c_3^0, c_4^0 = c_4^0, c_3^0 = c_3^0,
\]
whence \( c_1 = \pm 1, c_4 = \pm 1, c_2 = \pm c_3^2 \);

– for \( e_1 = e_4 = 1, e_2 = 2, e_3 = 3 \) we have \( S = \{1, 4\}, O = \{3\}, E = \{2\} \), and
\[
\sum_{j=1}^{n} c_j = c_1^0, c_2^0 = c_2^0, c_1^0 = c_1^0, c_2^0 = c_3, c_2^0 = c_4, c_3^0 = c_4^0 = c_4^2,
\]
whence \( c_1 = c_4 = 1, c_3 = c_2^2 > 0; \)

– for \( e_1 = 1, e_2 = 2, e_3 = 3, S = \{1\} E = \{2\}, O = \{3\} \). Suppose \( c_2 = 6 \), so both the primes 2 and 3 divide \( c_2 \). From \( c_1 = c_2^0, c_2^2 = c_3^0, c_2^3 = c_3 \) we get \( c_1 = 1 \) and \( c_3 = 36 \). We notice that 2 \( | c_3 \) and 3 \( | c_3 \), but neither 2 nor 3 divide \( c_1 \);

– for \( e_1 = e_4 = 1, e_2 = 4, e_3 = 8 \) we have \( S = \{1, 4\}, E = \{2, 3\}, O = \emptyset \) and
\[
\sum_{j=1}^{n} c_j = c_1 = c_2, c_1 = c_1 = c_2, c_3^2 = c_4, c_3^0 = c_4^0 = c_4^2,
\]
whence \( c_1 = c_4 = 1, c_2 = \chi^3, c_3 = \chi^7, c_2c_3 > 0 \), for some \( \chi \in \mathbb{Z} \setminus \{0\} \).

As regards the values \(|c_i|, 1 \leq i \leq n\), setting
\[
\rho := \sum_{j=1}^{n} (e_j - 1) = \sum_{j=1}^{n} (e_j - 1), \chi := \sqrt[4]{\prod_{j=1}^{n} |c_j|} \in \mathbb{N} \setminus \{0\},
\]
we have
\[
|c_i| = \chi^{2^{i-1}} \text{ for each } j \in \{1, \ldots, n\}. \tag{1-c}
\]

In fact, since if a prime \( p \) divides at least a \( c_j, j \in I \), then it divides each \( c_i, i \in I \), we can express each \( |c_i| = p_1^{\rho_1} \cdots p_h^{\rho_h} \) where \( p_1, \cdots, p_h \) are the prime factors of the squarefree associate \( \sqrt{\chi} = p_1 \cdots p_h \).

We have
\[
|c_i|^{\rho_i} = |c_i|^{\rho_i-1} \implies p^{\rho_i(e_i-1)} = p^{\rho_i(e_i-1)} \implies a_i(e_i - 1) = a_i(e_i - 1)
\]
whence \( a_i = a_j \iff e_i = e_j \) and \( a_i > a_j \iff e_j < e_i \).

Thus the \( c_i \)'s with minimal \( e_i \) minimalize also all \( a_i, 1 \leq l \leq h \).

We moreover have \( a_{ij} = \frac{a_i(e_i-1)}{(e_j-1)}, 1 \leq l \leq h \).

Therefore
\[
\prod_{j=1}^{n} |c_j| = \prod_{j=1}^{n} p_j^{a_{ij}} = \prod_{j=1}^{n} p_j^{a_{ij}} = \prod_{j=1}^{n} p_j^{a_{ij} \rho_j \rho_i(e_j-1)} = \prod_{j=1}^{n} p_j^{\frac{a_{ij}}{e_j-1}}
\]
whence
\[
\chi := \sqrt[4]{\prod_{j=1}^{n} |c_j|} = \sqrt[4]{\prod_{j=1}^{n} p_j^{\frac{a_{ij}}{e_j-1}}} = \prod_{j=1}^{n} p_j^{\frac{a_{ij}}{e_j-1}}
\]
and (1-c).

The formula (1-c) allows to reformulate (1-b) as
\[
|c_i|^{\rho_i} = |c_i|^{\rho_i-1} = \chi^{(e_i-1)(e_j-1)}. \tag{1-d}
\]
Note that we have
\[ \chi^{(e_i-1)(e_j-1)} = \chi^{(e_i-1)\gamma(a,\epsilon)(e_j-1)\gamma(a,\epsilon)} = |c_i|^{(e_i-1)\gamma(a,\epsilon)} = |c_j|^{(e_j-1)\gamma(a,\epsilon)}. \]

and
\[ |c_i|^{\gamma(a,\epsilon)}|c_j|^{\gamma(a,\epsilon)}|c_{ij}|^{\gamma(a,\epsilon)} = |c_i|^{\gamma(a,\epsilon)}|c_j|^{\gamma(a,\epsilon)} = \chi^{e_i e_j^{-1}}. \quad (1-e) \]

Now we explain how to deduce a general formula for the product of two “monomials” in this context.

To avoid cumbersome and useless case-to-case studies, let us simply assume \( c_i > 0 \) for each \( i \); under this restricted assumption, a series of inductive arguments allows to deduce
\[ Y_i \ast x^a = c_i^a x^{ab} Y_i, \quad (2-a) \]
\[ Y_{ij} \ast x^{b_j} = c_j^{b_j \gamma(a,\epsilon)} x^{b_j e_j} Y_{ij}. \quad (2-b) \]

Substituting \( c_j = \chi^{e_j} \) and \( c_i = \chi^{e_i} \) we get
\[ Y_{ij} \ast x^{b_j} = c_j^{b_j \gamma(a,\epsilon)} x^{b_j e_j} \chi^{b_j e_j e_i^{-1}} = \chi^{b_j e_j e_i^{-1}} Y_{ij}. \quad (2-c) \]
\[ Y_{ij} \ast x^{b_j} = c_j^{b_j \gamma(a,\epsilon)} x^{b_j e_j} \chi^{b_j e_j e_i^{-1}} Y_{ij} = \chi^{b_j e_j e_i^{-1}} Y_{ij}. \quad (2-d) \]

In conclusion
\[ (ax^{a_1} \cdots Y_{i_n}) \ast (bx^{b_1} \cdots Y_{n_n}) = ab \chi^{b_0((\Pi_{i=1} e_i^{-1})-1) x^{a_0+b_0} \Pi_{i=1} e_i^{-1} y_i^{a_0+b_0} \cdots Y_{n_0+b_0} + d_0}. \quad (2-e) \]

Note that associativity is verified by
\[ \left[ (ax^{a_1} \cdots Y_{i_n}) \ast (bx^{b_1} \cdots Y_{n_n}) \right] \ast (dx^{d_1} \cdots Y_{n_n}) = ab \left[ \left[ (ax^{a_1} \cdots Y_{i_n}) \ast (bx^{b_1} \cdots Y_{n_n}) \right] \ast (dx^{d_1} \cdots Y_{n_n}) \right] \]
\[ = ab \chi^{b_0((\Pi_{i=1} e_i^{-1})-1) x^{a_0+b_0} \Pi_{i=1} e_i^{-1} y_i^{a_0+b_0} \cdots Y_{n_0+b_0} + d_0} \]
and
\[ (ax^{a_1} \cdots Y_{i_n}) \ast \left[ (bx^{b_1} \cdots Y_{n_n}) \ast (dx^{d_1} \cdots Y_{n_n}) \right] = ab \chi^{b_0((\Pi_{i=1} e_i^{-1})-1) x^{a_0+b_0} \Pi_{i=1} e_i^{-1} y_i^{a_0+b_0} \cdots Y_{n_0+b_0} + d_0}. \]
2 Buchberger Theory

In this section, $R$ is a not necessarily commutative domain and $R$ a multivariate Ore extension.

2.1 Term ordering

For each $m \in \mathbb{N}$, the free $R$-module $R^m$ – the canonical basis of which will be denoted $\{e_1, \ldots, e_m\}$ – is an $(R, R)$-bimodule with basis the set of the terms

$\mathcal{T}^{(m)} := \{te_i : t \in \mathcal{T}, 1 \leq i \leq m\}$.

If we impose on $\mathcal{T}^{(m)}$ a total ordering $<$, then each $f \in R^m$ has a unique representation as an ordered linear combination of terms $t \in \mathcal{T}^{(m)}$ with coefficients in $R$:

$$f = \sum_{i=1}^{s} c(f, t_i) t_i : c(f, t_i) \in R \setminus \{0\}, t_i \in \mathcal{T}^{(m)}, t_1 \succ \cdots \succ t_s.$$ 

The support of $f$ is the set $\text{supp}(f) := \{t \mid c(f, t) \neq 0\}$.

W.r.t. $<$ we denote $\text{T}(f) := t_1$ the maximal term of $f$, $\text{lc}(f) := c(f, t_1)$ its leading coefficient and $\text{M}(f) := c(f, t_1)r_1$ its maximal monomial.

If we denote, following [45, 46], $\text{M}(R^m) := \{cte_i \mid c \in R \setminus \{0\}, t \in \mathcal{T}, 1 \leq i \leq m\}$, for each $f \in R^m \setminus \{0\}$, the unique finite representation above can be reformulated

$$f = \sum_{r \in \text{supp}(f)} m_r, m_r = c(f, r)r,$$ 

as a sum of elements of the monomial set $\text{M}(R^m)$.

Fixed a term ordering $<$ on $\mathcal{T}$ a $<$-compatible term ordering $<$ on $\mathcal{T}^{(m)}$ is a well-ordering on $\mathcal{T}^{(m)}$ which satisfies

$$\omega_1 \prec \omega_2 \implies \omega_1 t \prec \omega_2 t, t\omega_1 \prec t\omega_2 \text{ for each } t \in \mathcal{T}^{(m)}, \omega_1, \omega_2 \in \mathcal{T}.$$ 

From now on, we suppose $<$ compatible with a given term ordering $<$ on $\mathcal{T}$.

While a multivariate Ore extension does not satisfy commutativity between terms and coefficients,

$$t \star r = rt \text{ for each } r \in R \setminus \{0\}, t \in \mathcal{T}^{(m)},$$

it however satisfies

$$\text{M}(t \star r) = \alpha_r(r)t, \text{ for each } r \in R \setminus \{0\}, t \in \mathcal{T}^{(m)}; \quad (3)$$

moreover, while $R$ is not a monoid ring under the multiplication $\star$, so that in particular we cannot claim $\tau \star \omega \in \mathcal{T}$ for $\tau, \omega \in \mathcal{T}$, however $\tau \star \omega$ satisfies

$$\text{T}(\tau \star \omega) = \tau \circ \omega \quad (4)$$

where we have denoted $\circ$ the (commutative) multiplication of $\mathcal{T}$; similarly, for $n \in \text{M}(R^m)$ and $m_l, m_r \in \text{M}(R) = \{ct : c \in R \setminus \{0\}, t \in \mathcal{T}\}$ we have $\text{M}(m_l \star n \star m_r) = m_l + n + m_r$.

In conclusion
2.2 Gröbner Bases

Consider a term ordering on $\mathcal{T}^{(m)}$, compatible with a term ordering on $\mathcal{T}$; with a slight abuse of notation we denote both of them by $\prec$.

For any set $F \subset \mathbb{R}^m$, we call $\mathbb{I}_L(F), \mathbb{I}_R(F), \mathbb{I}_2(F)$ the left (resp. right, bilateral) module generated by $F$, and

$\text{1. } \mathbb{T}_L(F) := \{T(f) : f \in F\} \subset \mathcal{T}^{(m)}$;
\hspace{1cm} $\mathbb{M}_L(F) := \{M(f) : f \in F\} \subset M(\mathbb{R}^m)$.

$\text{2. } \mathbb{T}_R(F) := \{T(\lambda \prec f) : \lambda \in \mathcal{T}, f \in F\} \subset \mathcal{T}^{(m)}$;
\hspace{1cm} $\mathbb{M}_R(F) := \{M(\lambda \prec f) : \lambda \in \mathcal{T}, f \in F\} \subset M(\mathbb{R}^m)$.

$\text{3. } \mathbb{T}_2(F) := \{T(\lambda \prec f \prec \rho) : \lambda, \rho \in \mathcal{T}, f \in F\} \subset \mathcal{T}^{(m)}$;
\hspace{1cm} $\mathbb{M}_2(F) := \{M(\lambda \prec f \prec \rho) : \lambda, \rho \in \mathcal{T}, f \in F\} \subset M(\mathbb{R}^m)$.

\text{Following an intuition by Weispfenning [53] we further denote}

$\text{4. } \mathbb{I}_W(F)$ the \textit{restricted} module generated by $F$,
\hspace{1cm} $\mathbb{I}_W(F) := \operatorname{Span}_\mathbb{R}(a f \prec \rho : a \in R \setminus \{0\}, \rho \in \mathcal{T}, f \in F)$,
\hspace{1cm} $\mathbb{T}_W(F) := \mathbb{T}_R(F)$,
\hspace{1cm} $\mathbb{M}_W(F) := \{M(a f \prec \rho) : a \in R \setminus \{0\}, \rho \in \mathcal{T}, f \in F\} \subset M(\mathbb{R}^m)$. 

\textbf{Corollary 15.} If $\prec$ is a term ordering on $\mathcal{T}$ and $\prec$ is a $\prec$-compatible term ordering on $\mathcal{T}^{(m)}$, then, for each $l, r \in \mathbb{R}$ and $f \in \mathbb{R}^m$,

\begin{enumerate}
\item $M(l \star f) = M(M(l) \star M(f)) = M(l) \star M(f)$;
\item $M(f \star r) = M(M(f) \star M(r)) = M(f) \star M(r)$;
\item $M(l \star f \star r) = M(M(l) \star M(f) \star M(r)) = M(l) \star M(f) \star M(r)$.
\end{enumerate}
If $R$ is a skew field, for each set $F \subseteq R^n$ we have

$$
\begin{align*}
M_L(F) &= M[I_L(M(F))] = I_L(M(F)) \cap M(R^n), \\
M_R(F) &= M[I_R(M(F))] = I_R(M(F)) \cap M(R^n), \\
M_2(F) &= M[I_2(M(F))] = I_2(M(F)) \cap M(R^n), \\
M_W(F) &= M[I_W(M(F))] = I_W(M(F)) \cap M(R^n).
\end{align*}
$$

(5)

Notation 16. From now on, in order to avoid cumbersome notation and boring repetitions, we will drop the subscripts when it will be clear of which kind of module (left, right, bilateral, restricted) we are discussing. As a consequence, the four statements of (5) will be summarized as

$$
M(F) = M[I(M(F))] = I(M(F)) \cap M(R^n).
$$

Similarly, we formulate a (left, right, bilateral, restricted) definition simply either for the left or for the bilateral case leaving to the reader the task to convert to the other cases.

For instance condition (ii) below is stated for the bilateral case; it would be reformulated:

left case for each $f \in I(F)$ there are $g \in F, a \in R \setminus \{0\}, \lambda \in T$ such that $M(f) = a\lambda \star M(g) = M(a \lambda \star g),$

right case for each $f \in I(F)$ there are $g \in F, b \in R \setminus \{0\}, \rho \in T$ such that $M(f) = M(g) \star bp = M(g \star bp),$

restricted case for each $f \in I(F)$ there are $g \in F, a \in R \setminus \{0\}, \rho \in T$ such that $M(f) = aM(g) \star \rho = M(ag \star \rho),$

\[\Box\]

The conditions in (5) imply that, if $R$ is a skew field, the following conditions are equivalent and can be naturally chosen as definition of Gröbner bases:

1. $M[I(F)] = M[I(M(F))] = M[I(M(F))] = I(M(F)) \cap M(R^n),$

2. for each $f \in I(F)$ there is $g \in F$ such that $M(g) \mid M(f).$

But in general between these statements there is just the implication (2) $\implies$ (1). Thus [40], there are two alternative natural definitions for the concept of Gröbner bases:

- a stronger one which satisfies the following equivalent conditions:

  (i). for each $f \in I(F)$ there is $g \in F$ such that $M(g) \mid M(f),$

  (ii). for each $f \in I(F)$ there are $g \in F, a, b \in R \setminus \{0\}, \lambda, \rho \in T$ such that $M(f) = a\lambda \star M(g) \star bp = M(a \lambda \star g \star bp),$

  (iii). $M[I(F)] = M[I(M(F))] = M(F);$

- and a weaker one which satisfies the following equivalent conditions:
(iv). for each $f \in \mathbb{I}(F)$ there are $g_i \in F$, $a_i, b_i \in R \setminus \{0\}$, $\lambda_i, \rho_i \in \mathcal{T}$ for which, denoting $\tau_i := T(g_i)$, one has

\[- \mathbf{T}(f) = \lambda_i \circ \mathbf{T}(g_i) \circ \rho_i \text{ for each } i, \text{ and } \mathbf{lc}(f) = \sum a_i \alpha_i \mathbf{lc}(g_i) \alpha_i \lambda_i \tau_i(b_i) \]

\[- \mathbf{M}(f) = \sum a_i \lambda_i \ast \mathbf{M}(g_i) \ast b_i \rho_i = \sum a_i \lambda_i \ast g_i \ast b_i \rho_i; \]

(v). $\mathbf{M}(\mathbb{I}(F)) = \mathbf{M}(\mathbb{I}(\mathcal{F})) = \mathbb{I}(\mathbf{M}(\mathcal{F})) = \mathbb{I}(\mathbf{M}(F)) \cap \mathbf{M}(\mathbb{R}^m)$;

if moreover $R$ is a skew field $\mathbf{M}(F) = \mathbb{M}(\mathbb{I}(\mathcal{F}))$ so that conditions (i-v) above are all equivalent and are also equivalent to

(vi). $\mathbf{T}(f) = \lambda \circ \mathbf{T}(g) \circ \rho$ for some $g \in F$, $\lambda, \rho \in \mathcal{T}$.

**Example 17.** Let us now specialize the ring of Example 14 to the case

\[ n = 3, e_1 = 2, e_2 = 3, e_3 = 4, \nu = 5, c_1 = 5, c_2 = 5^2, c_3 = 5^3 \]

and remark that

\[ ax^{a_0}y_1^{a_2}y_2^{a_3} = bx^{b_0}y_1^{b_1}y_2^{b_2}y_3^{b_3} = ab5^{b_0(2^n-1)}x^{a_0+b_0}y_1^{a_1+b_1}y_2^{a_2+b_2}y_3^{a_3+b_3}. \]

As a consequence, for each $(b_0, b_1, b_2, b_3), (j_0, j_1, j_2, j_3) \in \mathbb{N}^4$, $b, j \in \mathbb{Z}$

\[ jx^{j_0}y_1^{j_1}y_2^{j_2}y_3^{j_3} \in \mathbb{I}(bx^{b_0}y_1^{b_1}y_2^{b_2}y_3^{b_3}) \]

if and only if

\[ a_0 := j_0 - b_0 \geq 0, a_2 := j_2 - b_2 \geq 0, a_3 := j_3 - b_3 \geq 0, a_0 := j_0 - b_02^{a_1} \geq 0 \quad (6) \]

and $b5^{b_0(2^n-1)} \mid j$.

Note that if we set $y := 5x$ then for each $(b_1, b_2, b_3), (j_1, j_2, j_3) \in \mathbb{Z}^3$ and $b(y), j(y) \in \mathbb{Z}[y] \subset R$

\[ j(y)x^{j_0}y_1^{j_1}y_2^{j_2}y_3^{j_3} \in \mathbb{I}(bx^{b_0}y_1^{b_1}y_2^{b_2}y_3^{b_3}) \]

if and only if, not only (6) but also $b(2^n y) \mid j(y)$.

**Definition 18.** Let $l \subset \mathbb{R}^m$ be a (left, right, bilateral, restricted) module and $G \subset l$.

- $G$ will be called
  - a (left, right, bilateral, restricted) weak Gröbner basis (Gröbner basis for short) of $l$ if
    \[ \mathbf{M}(l) = \mathbf{M}(l) = \mathbf{M}(\mathbb{I}(\mathcal{M}(G))) = \mathbb{I}(\mathbf{M}(G)) \cap \mathbf{M}(\mathbb{R}^m), \]
    
    _id est_ if $G$ satisfies conditions (iv-v) w.r.t. the module $l = \mathbb{I}(G)$; in particular $\mathbf{M}(G)$ generates the (left, right, bilateral, restricted) module $\mathbf{M}(l) \subset \mathbb{R}^m$;
  - a (left, right, bilateral, restricted) strong Gröbner basis of $l$ if for each $f \in l$ there is $g \in G$ such that $\mathbf{M}(g) \mid \mathbf{M}(f)$, _id est_ if $G$ satisfies conditions (i-iii) w.r.t. the module $l = \mathbb{I}(G)$. 

15
We say that \( f \in \mathbb{R}^m \setminus \{0\} \) has

- a left Gröbner representation in terms of \( G \) if it can be written as \( f = \sum_{i=1}^\mu l_i \star g_i \), with \( l_i \in \mathbb{R}, g_i \in G \) and \( T(l_i) \circ T(g_i) \leq T(f) \) for each \( i \);

- a left (weak) Gröbner representation in terms of \( G \) if it can be written as \( f = \sum_{i=1}^\mu a_i \lambda_i \star g_i \), with \( a_i \in R \setminus \{0\}, \lambda_i \in T, g_i \in G \) and \( \lambda_i \circ T(g_i) \leq T(f) \) for each \( i \);

- a left (strong) Gröbner representation in terms of \( G \) if it can be written as \( f = \sum_{i=1}^\mu a_i \lambda_i \star g_i \), with \( a_i \in R \setminus \{0\}, \lambda_i \in T, g_i \in G \) and
  \[
  T(f) = \lambda_1 \circ T(g_1) > \lambda_i \circ T(g_i) \text{ for each } i;
  \]

- a restricted (weak) Gröbner representation in terms of \( G \) if it can be written as \( f = \sum_{i=1}^\mu a_i \lambda_i \star g_i \), with \( a_i \in R \setminus \{0\}, \lambda_i \in T, g_i \in G \) and \( \lambda_i \circ T(g_i) \circ \rho_i \leq T(f) \) for each \( i \);

- a restricted (strong) Gröbner representation in terms of \( G \) if it can be written as \( f = \sum_{i=1}^\mu a_i \lambda_i \star g_i \), with \( a_i \in R \setminus \{0\}, \lambda_i \in T, g_i \in G \) and \( T(f) = T(g_1) \circ \rho_1 > T(g_i) \circ \rho_i \) for each \( i \).

For \( f \in \mathbb{R}^m \setminus \{0\}, F \subset \mathbb{R}^m \), an element \( h := \text{NF}(f, F) \in \mathbb{R}^m \) is called a

- (left, right, bilateral, restricted) (weak) normal form of \( f \) w.r.t. \( F \), if \( f - h \in \mathbb{I}(F) \) has a weak Gröbner representation in terms of \( F \), and \( h \neq 0 \implies M(h) \neq M[\mathbb{I}(M(F))] \);

- (left, right, bilateral, restricted) strong normal form of \( f \) w.r.t. \( F \), if \( f - h \in \mathbb{I}(F) \) has a strong Gröbner representation in terms of \( F \), and \( h \neq 0 \implies M(h) \neq M(F) \).
Proposition 19. (cf. [45, 46]) For any set \( F \subset \mathbb{R}^m \setminus \{0\} \), among the following conditions:

1. \( f \in \mathbb{I}(F) \iff \text{it has a (left, right, bilateral, restricted) strong Gröbner representation} \ f = \sum_{i=1}^{\mu} a_i \lambda_i \star g_i \star \rho_i \text{ in terms of } F \text{ which further satisfies} \)
   \[ T(f) = \lambda_1 \circ T(g_1) \circ \rho_1 > \cdots > \lambda_i \circ T(g_i) \circ \rho_i > \cdots ; \]

2. \( f \in \mathbb{I}(F) \iff \text{it has a (left, right, bilateral, restricted) strong Gröbner representation in terms of } F; \)

3. \( F \) is a (left, right, bilateral, restricted) strong Gröbner basis of \( \mathbb{I}(F) \);

4. \( f \in \mathbb{I}(F) \iff \text{it has a (left, right, bilateral, restricted) weak Gröbner representation in terms of } F; \)

5. \( F \) is a (left, right, bilateral, restricted) Gröbner basis of \( \mathbb{I}(F) \);

6. \( f \in \mathbb{I}(F) \iff \text{it has a (left, right) Gröbner representation in terms of } F; \)

7. for each \( f \in \mathbb{R}^m \setminus \{0\} \) and any (left, right, bilateral, restricted) strong normal form \( h \) of \( f \) w.r.t. \( F \) we have \( f \in \mathbb{I}(F) \iff h = 0; \)

8. for each \( f \in \mathbb{R}^m \setminus \{0\} \) and any (left, right, bilateral, restricted) weak normal form \( h \) of \( f \) w.r.t. \( F \) we have \( f \in \mathbb{I}(F) \iff h = 0; \)

there are the implications

\[
\begin{align*}
(1) & \iff (2) \Rightarrow (4) \iff (6) \\
& \uparrow \quad \Downarrow \quad \Downarrow \quad \nearrow \\
(7) & \iff (3) \Rightarrow (5) \Rightarrow (8)
\end{align*}
\]

If \( R \) is a skew field we have also the implication (4) \( \Rightarrow \) (2) and as a consequence also (5) \( \Rightarrow \) (3).

Proof. The implications (1) \( \Rightarrow \) (2) \( \Rightarrow \) (4) \( \iff \) (6), (3) \( \Rightarrow \) (5), (2) \( \Rightarrow \) (3) and (4) \( \Rightarrow \) (5) are trivial.

(3) \( \Rightarrow \) (1): for each \( f \in \mathbb{I}_2(F) \), by assumption, there are elements \( g \in F, m = a\lambda, n = b\rho \in M(R) \) such that \( M(f) = M(m \star g \star n) \). Thus \( T(f) = T(m \star g \star n) = \lambda \circ T(g) \circ \rho \) and, denoting \( f_1 := f - m \star g \star n \), we have \( T(f_1) < T(f) \) so the claim follows by induction, since \( < \) is a well ordering.

(5) \( \Rightarrow \) (4): similarly, for each \( f \in \mathbb{I}_2(F) \) by assumption there are elements \( g_i \in F, T(g_i) := \tau_i e_i, m_i = a_i \lambda_i, n_i = b_i \rho_i \in M(R) \) such that

- \( T(f) = T(\lambda_i \star g_i \star \rho_i) = \lambda_i \circ \tau_i \circ \rho_i e_i \) for each \( i \),
- \( \text{lc}(f) = \sum_i a_i \alpha_i (\text{lc}(g_i)) \alpha_i \tau_i (b_i) \). 

17
It is then sufficient to denote \( f_i := f - \sum_i m_i \bigstar g_i \bigstar n_i \) in order to deduce the claim by induction, since \( T(f_i) < T(f) \) and \(< \) is a well ordering.

(4) \( \implies \) (2): let \( f \in \hat{I}_2(F) \setminus \{0\} \); (4) implies the existence of \( g \in F, \lambda, \rho \in T \), such that \( T(f) = \lambda \circ T(g) \circ \rho \). Then setting \( f_i := f - \text{lcm}(f)(\alpha_\delta(\text{lcm}(g)))^{-1} \lambda \bigstar g \bigstar \rho \) we deduce the claim by induction, since \( T(f_i) < T(f) \) and \(< \) is a well ordering.

(3) \( \implies \) (7) and (5) \( \implies \) (8): either

- \( h = 0 \) and \( f = f - h \in \hat{I}(F) \) or
- \( h \neq 0 \), \( M(h) \notin M(\hat{I}(F)) \), \( h \notin \hat{I}(F) \) and \( f \notin \hat{I}(F) \).

(7) \( \implies \) (2) and (8) \( \implies \) (4): for each \( f \in \hat{I}(F) \), its normal form is \( h = 0 \) and \( f = f - h \) has a strong (resp.: weak) Gröbner representation in terms of \( F \).

\[ \square \]

**Proposition 20.** (Compare [31, Proposition 22.2.10]) If \( F \) is a (weak, strong) Gröbner basis of \( \mathfrak{l} : = \hat{I}(F) \), then the following holds:

1. Let \( g \in \mathbb{R}^m \) be a (weak, strong) normal form of \( f \) w.r.t. \( F \). If \( g \neq 0 \), then
   \[ T(g) = \min\{T(h) : h - f \in \hat{I}(F)\} \]

2. Let \( f, f' \in \mathbb{R}^m \setminus \mathfrak{l} \) be such that \( f - f' \in \mathfrak{l} \). Let \( g \) be a (weak, strong) normal form of \( f \) w.r.t. \( F \) and \( g' \) be a (weak, strong) normal form of \( f' \) w.r.t. \( F \). Then
   \[ T(g) = T(g') : \tau \text{ and } \text{lcm}(g) - \text{lcm}(g') \in \mathfrak{l}, := \{\text{lcm}(f) : f \in \mathfrak{l}, T(f) = \tau\} \cup \{0\} \subset R. \]

**Proof.**

1. Let \( h \in \mathbb{R}^m \) be such that \( h - f \in \mathfrak{l} \); then \( h - g \in \mathfrak{l} \) and \( M(h - g) \notin M(\mathfrak{l}) \). If \( T(g) > T(h) \) then \( M(h - g) = M(g) \notin M(\mathfrak{l}) \), giving a contradiction.

2. The assumption implies that \( f - g' \in \mathfrak{l} \) so that, by the previous result, \( T(g) \leq T(g') \). Symmetrically, \( f' - g \in \mathfrak{l} \) and \( T(g') \leq T(g) \). Therefore \( T(g) = T(g') = \tau \); moreover, either
   \[ T(g - g') < \tau \text{ and } M(g) = M(g') \text{ so that } \text{lcm}(g) = \text{lcm}(g') \text{ or } \]
   \[ T(g - g') = \tau \text{ and } M(g - g') = M(g) - M(g') = (\text{lcm}(g) - \text{lcm}(g'))\tau; \text{ thus, since } g \in \mathfrak{l}, \text{lcm}(g) - \text{lcm}(g') \in \mathfrak{l}. \]

\[ \square \]

### 2.3 Canonical forms (skew field case)

If \( R : = \mathbb{K} \) is a skew field, for any set \( F \subset \mathbb{R}^m \) we denote \( N(F) \) the (left, right, bilateral, restricted) order module \( N(F) : = T^{(m)} \setminus T(F) \) and \( \mathbb{K}[N(F)] \) the (left, right, bilateral, restricted) \( \mathbb{K} \)-module \( \mathbb{K}[N(F)] : = \text{Span}_\mathbb{K}(N(F)) \).
(g, \sum_{i=1}^{\mu} c_i \lambda_i \ast g_i) := \textbf{LeftCanonicalForm}(f, G)

where

G is the left Gröbner basis of the left module \( l \subset \mathbb{R}^n \),

\( f \in \mathbb{R}^n \), \( g \in \mathbb{K}[N(l)] \), \( c_i \in \mathbb{E} \setminus \{0\} \), \( \lambda_i \in \mathcal{T} \), \( g_i \in G \).

\( f - g = \sum_{i=1}^{\mu} c_i \lambda_i \ast g_i \) is a left strong Gröbner representation in terms of \( G \),

\( T(f - g) = \lambda_1 \circ T(g_1) > \lambda_2 \circ T(g_2) > \cdots > \lambda_{\mu} \circ T(g_{\mu}). \)

\( h := f, i := 0, g := 0, \)

While \( h \neq 0 \) do

\( % f = g + \sum_{j=1}^{i} c_j \lambda_j \ast g_j + h, \)

\( % T(f - g) \geq T(h); \)

\( % i > 0 \Rightarrow T(f - g) = \lambda_1 \circ T(g_1) > \lambda_2 \circ T(g_2) > \cdots > \lambda_i \circ T(g_i) > T(h); \)

If \( T(h) \in T_L(G) \) do

Let \( \lambda \in \mathcal{T}, \gamma \in G : \lambda \circ T(\gamma) = T(h) \)

\( \bullet i := i + 1, c_i := \text{lcm}(h)\pi_\lambda (\text{lcm}(\gamma))^{-1}, \lambda_i := \lambda, g_i := \gamma, h := h - c_i \lambda_i g_i. \)

Else

\( % T(h) \in N(l) \)

\( g := g + M(h), h := h - M(h) \)

\( \textbf{Figure 1: Canonical Form Algorithms} \)
**Definition 21.** For any (left, right, bilateral, restricted) module $I \subset \mathbb{R}^m$, the order module $N(I) = T(m) \setminus T(I)$ is called the **escalier** of $I$.

We easily obtain the notion, the properties and the computational algorithm (Figure 1 and Remark 25) of (left, right, bilateral, restricted) canonical forms:

**Lemma 22.** (cf. [31, Lemma 22.12]) Let $I \subset \mathbb{R}^m$ be a (left, right, bilateral, restricted) module. If $R = \mathbb{K}$ is a skew field and denoting $A$ the (left, right, bilateral, restricted) module $A := \mathbb{R}^m/I$ it holds

1. $\mathbb{R}^m \cong 1 \oplus \mathbb{K}[N(I)]$;
2. $A \cong \mathbb{K}[N(I)]$;
3. for each $f \in \mathbb{R}^m$, there is a unique
   
   $$g := \text{Can}(f, I) = \sum_{t \in N(I)} \gamma(f, t, <) t \in \mathbb{K}[N(I)]$$

   such that $f - g \in I$.

   Moreover:
   
   (a) $\text{Can}(f_1, I) = \text{Can}(f_2, I) \iff f_1 - f_2 \in I$;
   (b) $\text{Can}(f, I) = 0 \iff f \in I$.

4. For each $f \in \mathbb{R}^m$, $f - \text{Can}(f, I)$ has a (left, right, bilateral, restricted) strong Gröbner representation in terms of any Gröbner basis.

**Definition 23.** (cf. [31, Definition 22.13]) For each $f \in \mathbb{R}^m$ the unique element

$$g := \text{Can}(f, I) \in \mathbb{K}[N(I)]$$

such that $f - g \in I$ will be called the (left, right, bilateral, restricted) **canonical form** of $f$ w.r.t. $I$. □

**Corollary 24.** (cf. [31, Corollary 22.14]) If $R = \mathbb{K}$ is a skew field, there is a unique set $G \subset I$ such that

- $T(G)$ is an irredundant basis of $T(I)$;
- for each $g \in G, \text{lc}(g) = 1$;
- for each $g \in G, g = T(g) - \text{Can}(T(g), I)$.

$G$ is called the (left, right, bilateral, restricted) **reduced** Gröbner basis of $I$. □

**Remark 25.** As regards Figure 1, we remark that the corresponding algorithm in the right, bilateral and restricted cases can be obtained from the one stated above via trivial modifications. The only nontrivial part is the one marked with • in the algorithm, which respectively becomes:

- **Left:** $i := i + 1, c_i := \text{lc}(h)\alpha_\lambda (\text{lc}(\gamma))^{-1}, \lambda_i := \lambda, g_i := \gamma, h := h - c_i \lambda_i g_i,$
• **Right:** \( i := i + 1, d_i := \alpha_i^{-1}(\text{lcm}(\gamma)) \), \( \rho_i := \rho, g_i := \gamma, h := h - g_i \star d_i \rho \);
• **Bilateral:** \( i := i + 1, c_i := \text{lcm}(\alpha_i(\text{lcm}(\gamma)))^{-1}, \lambda_i := \lambda, \rho_i := \rho, g_i := \gamma, h := h - c_i \lambda_i \star g_i \star \rho_i \);
• **Restricted:** \( i := i + 1, c_i := \text{lcm}(\gamma)^{-1}, \rho_i := \rho, g_i := \gamma, h := h - c_i g_i \star \rho_i \).

Note that the algorithm described for right canonical forms is assuming that each \( \alpha_i \) is an automorphism; alternatively we can assume that \( R \) is given as a right \( R \)-module in which case the theory can be developed symmetrically.

### 3 Szekeres Theory

In this section, \( R \) is a non necessarily commutative domain and \( R \) a multivariate Ore extension.

Let \( I \subset R^n \) be a (left, bilateral) module; if we denote for each \( \tau \in T^{(m)} \), \( l_\tau \) the additive group

\[
l_\tau := \{ \text{lcm}(f) : f \in I, T(f) = \tau \} \cup \{ 0 \} \subset R,
\]

\( \mathcal{Z} := \{ l_\tau : \tau \in T^{(m)} \} \) and, for each ideal \( a \subset R \), \( T_a \) and \( L_a \) the sets

\[
T_a := \{ \tau \in T^{(m)} : l_\tau \supseteq a \} \subset T^{(m)} \quad \text{and} \quad L_a := \{ \tau \in T^{(m)} : l_\tau = a \} \subset T^{(m)},
\]

we have

1. for each \( \tau \in T^{(m)}, l_\tau \subset R \) is a left ideal;
2. for each ideals \( a, b \subset R \), \( a \subset b \implies T_a \supset T_b \);
3. \( T_a \geq \bigsqcup_{b \supset a} L_b, L_a = T_a \setminus \bigsqcup_{b \supset a} T_b \);
4. for terms \( \tau, \omega \in T^{(m)}, \tau | \omega \implies l_\tau \subset l_\omega \);
5. for each ideal \( a \subset R \), \( T_a \subset T^{(m)} \) is a semigroup module. \( \Box \)

If \( R \) is a skew field, the situation is quite trivial: for any ideal \( l \) we have

\[
\mathcal{Z} = \{ (0), R \}, T_R = L_R = T(l), T(0) = T^{(m)}, L(0) = T^{(m)} \setminus T(l).
\]

Szekeres notation is related with a pre-Buchberger construction of “canonical” ideals for the case of polynomial rings \( R[Y_1, \ldots, Y_n] \) over a PID \( R \).

In connection recall that [14, 15] a not necessarily commutative ring \( R \) is called a (left, right, bilateral) Bézout ring if every finitely generated (left, right, bilateral) ideal is principal and is called a Bézout domain if it is both a Bézout ring and is a domain, and remark that, if \( R \) is a noetherian (left, bilateral) Bézout ring, then for each \( \tau \in T^{(m)} \), there is a value \( c_\tau \in R \) satisfying \( l_\tau = l(c_\tau) \).
Definition 26. With the present notation, we call Szekeres ideal each ideal \( l_\tau \subset R \), Szekeres level each set \( L_\omega \subset T^{(m)} \) and Szekeres semigroup each semigroup \( T_\omega \subset T^{(m)} \).

Finally, if \( R \) is a noetherian left Bézout ring we call Szekeres generator each value \( c_\tau \in R \) satisfying \( l_\tau = \mathbb{I}_{l_\tau}(c_\tau) \).

Note that if \( R \) is a noetherian Bézout ring, we have,
\[
\omega \triangleright \tau \implies c_\tau \mid_{L_\omega} \alpha_\lambda(c_\omega) \text{ for each } \lambda, \rho \in T \text{ s.t. } \tau = \lambda \circ \omega \circ \rho.
\]

Proposition 27 (Szekeres). [51] Let \( R \) be a noetherian left Bézout ring and \( l \subset R^m \) be a (left, bilateral) module. Denote
\[
T := \{ \tau \in T^{(m)} \text{ s.t. } c_\tau \notin \llbracket (\alpha_\lambda(c_\omega), \omega \in T^{(m)}, \lambda, \rho \in T, \tau = \lambda \circ \omega \circ \rho) \rrbracket \subset T^{(m)} \}
\]
and fix, for each \( \tau \in T \), any element \( f_\tau \in l \) such that \(^2 \mathbf{M}(f_\tau) = c_\tau T\). Then the basis \( S_w := \{ f_\tau \text{ s.t. } \tau \in T \} \) is a left/bilateral weak Gröbner basis of \( l \).

Proof. For each \( f \in l \), denoting \( \tau := T(f) \) we have \( \text{lc}(f) \in \mathbb{I}_{l_\tau}(c_\tau) \) and \( \text{lc}(f) = dc_\tau \) for suitable \( d \in R \setminus \{0\} \). Thus if \( \tau \in T \) we have \( \mathbf{M}(f) = d \mathbf{M}(f_\tau) \); if, instead, \( \tau \notin T \) there are suitable \( d_\tau, c_\tau, \omega_\tau, \rho_\tau \in T \) for which \( \lambda_\tau \circ \omega_\tau \circ \rho_\tau = \tau \) and \( c_\tau = \sum_i d_i \alpha_\lambda(c_\omega) \) so that
\[
\mathbf{M}(f) = dc_\tau \tau = d \left( \sum_i d_i \alpha_\lambda(c_\omega) \lambda_i \circ \omega_i \circ \rho_i \right)
= \sum_i (dd_i \lambda_i) \cdot (c_\omega \omega_i) \cdot \rho_i
= \sum_i (dd_i \lambda_i) \ast \mathbf{M}(f_\omega) \ast \rho_i.
\]

\[\square\]

Remark 28. Remark that in the case in which each endomorphism \( \alpha_\tau, \tau \in T^{(m)} \), is an automorphism, we can consider also right modules \( l \) to which we can associate
\[
l_\tau = \{ \text{lc}(f) : f \in l, T(f) = \tau \} \cup \{0\}
\]
which are right ideals themselves; in fact if we represent \( f \in R^m \) as (see Remark 3)
\[
f = \sum_{i=1}^n Y_i \tilde{a}_i \text{ and we denote } I \text{ the right ideal}
\]
\[
\tau I := \{ c \in R : \tau c \in \mathbf{M}(I) \} \cup \{0\} \subset R
\]
then \( l_\tau \) is the right ideal \( \alpha_\tau(I) \).

However, in this setting, Szekeres Theory can be built more easily by considering the ideals \( l \) obtained through the right representation of Remark 3 and adapting to them the results reported above.

Remark that if an endomorphism \( \alpha_\tau \) is not invertible, in general \( l_\tau \) is not an ideal but just an additive group.

Finally note that for restricted modules, one applies verbatim, the classical Szekeres theory and substitute in the results above each instance of \( \alpha_\lambda(c_\omega), \tau = \lambda \circ \omega \circ \rho \) with \( c_\omega, \tau = \omega \circ \rho \).

\[\square\]

\(^2\)Of course for the extreme case \( l_\tau = \{0\} \) so that \( c_\tau = 0 \), we have \( f_\tau := 0 \).
Example 29. In the Ore extension
\[ R := R[Y; \alpha], R = \mathbb{Z}_2[x] \text{ where } \alpha : R \to R : x \mapsto x^2 \]
we can consider, as a left module, the two-sided ideal \( I_2(x) = I_2[xY^i : i \in \mathbb{N}] \); we thus have
\[ I_\tau = I(x) \subseteq R \text{ for each } \tau \in \{ Y^i, i \geq 0 \}, \]
so that, setting \( a := I(x) \subseteq R \), we have, e.g.
\[ I_Y = \{ x \phi(x^i) : \phi(x) \in \mathbb{Z}_2[x] \}. \]

4 Zacharias canonical representation

Let \( R, R \) be two rings such that \( R \) is also a left \( R \)-module. Following Zacharias approach to Buchberger Theory [54], if each module \( I \subseteq R^m \) has a groebnerian property, necessarily the same property must be satisfied at least by the modules \( I \subseteq R^m \subseteq R^m \) and thus such property in \( R^m \) can be used to devise a procedure granting the same property in \( R^m \). The most elementary application of Zacharias approach is the generalization of the property of canonical forms from the case in which \( R = K \) is a skew field to the general case: all we need is an effective notion of canonical forms for modules in \( R \):

**Definition 30** (Zacharias). [54] A ring \( R \) is said to have canonical representatives if there is an algorithm which, given an element \( c \in R^m \) and a (left, bilateral, right) module \( J \subseteq R^m \), computes a unique element \( \text{Rep}(c, J) \) such that
- \( c - \text{Rep}(c, J) \in J \),
- \( \text{Rep}(c, J) = 0 \iff c \in J \).

The set
\[ \text{Rep}(J) := \{ \text{Rep}(c, J) : c \in R^m \} \cong R^m/J \]
is called the canonical Zacharias representation of the module \( R^m/J \).

Remark that, for each \( c, d \in R^m \) and each module \( J \subseteq R^m \), we have
\[ c - d \in J \iff \text{Rep}(c, J) = \text{Rep}(d, J). \]

Using Szekeres notation for a (left, right, bilateral) module \( l \subseteq R^m \) we obtain
- the partition \( T^{(m)} = L(l) \sqcup R(l) \sqcup N(l) \) of \( T^{(m)} \) where
  - \( N(l) := L_{(0)} = \{ \omega \in T^{(m)} : l_\omega = (0) \} \),
  - \( L(l) := L_R = \{ \omega \in T^{(m)} : l_\omega = R \} \),
  - \( R(l) := \{ \omega \in T^{(m)} : l_\omega \notin [(0), R] \} \);
– the canonical Zacharias representation

\[
\text{Rep}(I) := \left\{ \text{Rep}(c, l) : c \in R^m \right\} = \bigoplus_{a \in \Lambda} \bigoplus_{\tau \in L_a} \text{Rep}(a)\tau = \bigoplus_{\tau \in T^{(m)}} \text{Rep}(l_\tau) \cong R^m/l
\]

of the module $R^m/l$.

If $R$ has canonical representatives and there is an algorithm (cf. Definition 40 (c), (e)) which, given an element $c \in R^m$ and a (left, right, bilateral) module $J \subset R^m$ computes the unique canonical representative $\text{Rep}(c, J)$, an easy adaptation of Figure 1 allows to extend, from the field coefficients case to the Zacharias ring [54, 32] coefficients case, the notion of canonical forms, the algorithm (Figure 2 and Remark 32) for computing them and their characterizing properties:

**Lemma 31.** If $R$ has canonical representatives, also $R$ has canonical representatives.

With the present notation and denoting, for a (left, right, bilateral) module $I \subset R^m$, $A$ the (left, right, bilateral) module $A := R^m/I$ it holds:

1. $R^m \cong I \oplus \text{Rep}(I)$;
2. $A \cong \text{Rep}(I)$;
3. for each $f \in R^m$, there is a unique (left, right, bilateral) canonical form of $f$

\[
g := \text{Can}(f, I) = \sum_{a \in \Lambda} \sum_{\tau \in L_a} \gamma(f, \tau, 1, <)\tau \in \text{Rep}(I), \quad \gamma(f, \tau, 1, <) \in \text{Rep}(l_\tau),
\]

such that

\[
- f - g \in I,
- \gamma(f, \tau, 1, <) = \text{Rep}(\gamma(f, \tau, 1, <), l_\tau) \in \text{Rep}(l_\tau), \text{ for each } \tau \in T^{(m)}.
\]

Moreover:

(a) $\text{Can}(f_1, I) = \text{Can}(f_2, I) \iff f_1 - f_2 \in I$;
(b) $\text{Can}(f, I) = 0 \iff f \in I$;

4. for each $f \in R^m$, $f - \text{Can}(f, I)$ has a (left, right, bilateral) (weak, strong) Gröbner representation in terms of any (weak, strong) Gröbner basis. \qed

**Remark 32.** As regards Figure 2, we remark that the corresponding algorithm in the right and bilateral cases can be obtained from the one stated above via trivial modifications. The only nontrivial part is the one marked with $\bullet$ in the algorithm, which respectively becomes:

- **Left:** $c - \gamma = \sum_{i=\mu+1}^{\nu} a_i \alpha_i(\text{lc}(g_i)), \quad T(g) = \lambda_i \circ T(g_i), \mu < i \leq \nu, \quad h := h - \sum_{i=\mu+1}^{\nu} a_i \lambda_i \star g_i, \quad \mu := \nu$.
(g, \sum_{i=1}^{n} a_i \lambda_i \ast g_i) := \textbf{LeftCanonicalForm}(f, F)

where

\[ R := R[T], R \text{ a ring with canonical representatives,} \]
\[ f \in R^m, F \text{ is the left Gröbner basis of the left module } l \subset R^m, \]
\[ g := \text{Can}(f, l) \in \text{Rep}(l), a_i \in R \setminus \{0\}, \lambda_i \in T, g_i \in F, \]
\[ f - g = \sum_{i=1}^{n} a_i \lambda_i \ast g_i \text{ is a left weak Gröbner representation in terms of } F, \]
\[ h := f, \mu := 0, g := 0 \]

While \( h \neq 0 \)

Let \( c \tau := M(h), \gamma := \text{Rep}(c, l) \)

\[ h := h - \gamma \tau, g := g + \gamma \tau, \]

If \( c \neq \gamma \), let \( g_i \in F, \lambda_i \in T, a_i \in R \setminus \{0\} : \]

- **Right:** \( c - \gamma = \sum_{i=1}^{r} a_i \lambda_i (lc(g_i)), T(g) = \lambda_i \circ T(g_i), \mu < i \leq \nu, h := h - \sum_{i=1}^{r} a_i \lambda_i \ast g_i, \mu := \nu \).

- **Bilateral:** \( c - \gamma = \sum_{i=1}^{r} a_i \lambda_i (lc(g_i)), T(g) = \lambda_i \circ T(g_i) \circ \rho_i, \mu < i \leq \nu, h := h - \sum_{i=1}^{r} a_i \lambda_i \ast g_i \circ \rho_i, \mu := \nu \).

5 Möller’s Lifting Theorem

Let \( R \) be a not necessarily commutative domain and \( R \) be a multivariate Ore extension.

5.1 Valuation

5.1.1 Left (right) case

The validity of Corollary 15 allows to introduce the groebnerian terminology and, as in the standard theory of commutative polynomial rings over a field [31, §21.1-2] or a Zacharias ring [54], the ability of imposing a \( T^{(m)} \)-valuation on modules over \( R \) and its associated graded Ore extension \( S := G(R) \) (see Remark 10).

The only twist w.r.t. the classical theory is that there the ring was coinciding with its associated graded ring; here they coincide as sets and as left \( R \)-modules, but as rings have two different multiplications.

Consequently, denoting by \( \ast \) the one of \( R \) and by \( \ast \) the one of \( S \), given a finite basis

\[ F := \{g_1, \ldots, g_n\} \subset R^m, g_i = M(g_i) - p_i =: c_i \tau e_i - p_i, \]
with respect to the module \( M := \mathbb{I}_L(F) \subset R^m \) we need to consider the morphisms
\[
s_L : S^u \to S^m : s_L \left( \sum_{i=1}^{u} h_i e_i \right) := \sum_{i=1}^{u} h_i \ast M(g_i),
\]
\[
\mathcal{E}_L : R^u \to M \subset R^m : \mathcal{E}_L \left( \sum_{i=1}^{u} h_i e_i \right) := \sum_{i=1}^{u} h_i \ast g_i,
\]
where the symbols \( \{ e_1, \ldots, e_u \} \) denote the common canonical basis of \( S^u \) and \( R^u \) which, as \( R \)-modules, coincide.

We can then consider
\( - \) the \( T^{(m)} \)-valuation \( \nu : R^u \to T^{(m)} \) defined, for each \( \sigma := \sum_{i=1}^{u} h_i e_i \in R^u \setminus \{ 0 \} \), by
\[
\nu(\sigma) := \max_{i} (T(h_i \ast g_i)) = \max_{i} (T_{<}(h_i) \circ T_{<}(g_i)) = \max_{i} (T_{<}(h_i) \circ \tau_{e_i}) =: \delta \epsilon
\]
under which we further have \( S^u = G(R^u) \);
\( - \) the corresponding leading form \( L_L(\sigma) := \sum_{h \in H} M(h) e_h \in S^u \) which is \( T^{(m)} \)-homogeneous of \( T^{(m)} \)-degree \( \nu(\sigma) = \delta \epsilon \) – where
\[
H := \{ j : T_{<}(h_j \ast g_j) = T_{<}(h_j) \circ \tau_{e_j} = \delta \epsilon = \nu(\sigma) \}.
\]
For each set \( S \subset R^u \), we denote \( L_L(S) := \{ L_L(g) : g \in S \} \subset S^u \).

### 5.1.2 Bilateral case

Considering \( R \) as a left \( R \)-module, the adaptation of Möller lifting theorem to the bilateral case requires a few elementary adaptations; given a finite set
\[
F := \{ g_1, \ldots, g_u \} \subset R^m, g_i = M(g_i) - p_i := c_i \tau_{e_i} - p_i,
\]
and the bilateral module \( M := \mathbb{I}_2(F) \), denote
\[
\hat{R} := \{ a \in R : ah = a \ast h = h \ast a, \text{ for each } h \in R \}
\]
the commutative subring \( \hat{R} \subset R \) consisting of the elements belonging to the center of \( R \) and remark that the subring of \( R \) generated by \( \mathbb{I}_R \) is a subring of \( \hat{R} \) and that \( \hat{R} \) is also a subring of the center of the associated graded Ore extension \( \hat{S} \) of \( R \).

Considering both the \( R \)-bimodule \( R \otimes_{\hat{R}} R^{op} \) and the \( S \)-bimodule \( S \otimes_{\hat{R}} S^{op} \), which, as sets, coincide, we impose on the bilateral \( R \)-module \( (R \otimes_{\hat{R}} R^{op})^u \), whose canonical basis is denoted \( \{ e_1, \ldots, e_u \} \) and whose generic element has the shape
\[
\sum_{i} a_i \lambda_i e_i b_i \rho_i, a_i, b_i \in R \setminus \{ 0 \}, \lambda_i, \rho_i \in T, 1 \leq \ell_i \leq u,
\]
the \( T^{(m)} \)-graded structure given by the valuation \( \nu : (R \otimes_{\hat{R}} R^{op})^u \to T \) as
\[
\nu(\sigma) := \max_{i} (T(\lambda_i \ast g_i \ast \rho_i)) = \max_{i} (|\lambda_i \ast T(g_i) \ast \rho_i|) = \max_{i} (\lambda_i \circ \tau_{e_i} \circ \rho_{e_i}) =: \delta \epsilon
\]

26
for each

$$\sigma := \sum_i a_i e_i \rho_i, a_i \in (R \otimes \hat{R} \mathcal{S}_\sigma)^u \setminus \{0\}$$

so that

$$G((R \otimes \hat{R} \mathcal{S}_\sigma)^u) = (G(R \otimes \hat{R} \mathcal{S}_\sigma))^u = (\mathcal{S} \otimes \hat{R} \mathcal{S}_\sigma)^u$$

and its corresponding $\mathcal{T}^{(m)}$-homogeneous leading form is

$$\mathcal{L}_2(\sigma) := \sum_{h \in H} a_h \lambda_h b_h \rho_h \in \mathcal{S} \otimes \hat{R} \mathcal{S}_\sigma^u$$

where $H := \{ j : \lambda_j \circ \tau_{\ell_j} \circ \rho_{\ell_j} e_{\ell_j} = \nu(\sigma) = \delta \epsilon \}$; we also denote, for each set $S \subset (R \otimes \hat{R} \mathcal{S}_\sigma)^u$,

$$\mathcal{L}_2[S] := \{ \mathcal{L}_2(g) : g \in S \} \subset (\mathcal{S} \otimes \hat{R} \mathcal{S}_\sigma)^u.$$

We can therefore consider the morphisms

$$\varphi_2 : (\mathcal{S} \otimes \hat{R} \mathcal{S}_\sigma)^u \to \mathcal{S}_\sigma^u : \varphi_2 \left( \sum_i a_i \lambda_i b_i \rho_i \right) := \sum_i a_i \lambda_i \ast \mathcal{M}(g_{\ell_i}) \ast b_i \rho_i,$$

$$\varphi_2 : (R \otimes \hat{R} \mathcal{S}_\sigma)^u \to \mathcal{S}_\sigma^u : \varphi_2 \left( \sum_i a_i \lambda_i b_i \rho_i \right) := \sum_i a_i \lambda_i \ast g_{\ell_i} \ast b_i \rho_i.$$

### 5.1.3 Restricted case

In order to deal with restricted modules, we need simply to adapt and simplify the bilateral case.

Thus, we consider both the left $R$-modules $R \otimes \mathcal{S}_\sigma^u$ and $R \otimes \mathcal{S}_\sigma^u$, which, as sets, coincide, we impose on the bilateral $R$-module $(R \otimes \mathcal{S}_\sigma)^u$, whose canonical basis is denoted $\{ e_1, \ldots, e_u \}$ and whose generic element has the shape

$$\sum_i a_i e_{\ell_i} \rho_i, a_i \in R \setminus \{0\}, \rho_i \in \mathcal{T}, 1 \leq \ell_i \leq u,$$

the $\mathcal{T}^{(m)}$-graded structure given by the valuation $\nu : (R \otimes \mathcal{S}_\sigma)^u \to T$ as

$$\nu(\sigma) := \max_{<} \{ T(g_{\ell_i} \ast \rho_i) \} = \max_{<} \{ T(g_{\ell_i} \ast \rho_i) \} = \max_{<} \{ \nu_{\ell_i} \circ \rho_{\ell_i} e_{\ell_i} \} = : \delta \epsilon$$

for each

$$\sigma := \sum_i a_i e_{\ell_i} \rho_i \in (R \otimes \hat{R} \mathcal{S}_\sigma)^u \setminus \{0\}$$

so that

$$G((R \otimes \mathcal{S}_\sigma)^u) = (G(R \otimes \mathcal{S}_\sigma))^u = (R \otimes \mathcal{S}_\sigma)^u$$

and its corresponding $\mathcal{T}^{(m)}$-homogeneous leading form is

$$\mathcal{L}_W(\sigma) := \sum_{h \in H} a_h \lambda_h b_h \rho_h \in (R \otimes \mathcal{S}_\sigma)^u$$

27
where $H := \{ j : \tau_j \circ \rho_j e_{t_j} = \nu(\sigma) = \delta \epsilon \}$; we also denote, for each set $S \subset (R \otimes R^{op})^{u}$,

$$L_w(S) := \{ L_w(g) : g \in S \} \subset (R \otimes S^{op})^{u}.$$  

We can therefore consider the morphisms

$$\varepsilon_w : (R \otimes S^{op})^{u} \to S^m : \varepsilon_w \left( \sum_{i} a_\ell e_{t_i} \rho_i \right) := \sum_{i} a_\ell M(g_\ell) \ast \rho_i,$$

$$\Xi_w : (R \otimes R^{op})^{u} \to R^{m} : \Xi_w \left( \sum_{i} a_\ell e_{t_i} \rho_i \right) := \sum_{i} a_\ell g_\ell \star \rho_i.$$  

### 5.2 Lifting Theorem

**Definition 33.** With the notation above

- for a (left, right, bilateral, restricted) $R$-module $N$, a set $B \subset N$ is called a (left, right, bilateral, restricted) **standard basis** if
  $$\mathbb{I}(L\{B\}) = \mathbb{I}(L\{N\});$$

- for each $h \in N$ a representation
  $$h = \sum_{i} l_i \ast g_i : l_i \in R, g_i \in B,$$
  is called a **left standard representation** in $R$ in terms of $B$ iff
  $$\nu(h) \geq \nu(l_i \ast g_i) = T(l_i) \circ T(g_i)$$ for each $i$;

- for each $h \in N$ a representation
  $$h = \sum_{i} g_i \ast r_i : r_i \in R, g_i \in B,$$
  is called a **right standard representation** in $R$ in terms of $B$ iff
  $$\nu(h) \geq \nu(g_i \ast r_i) = T(g_i) \circ T(r_i)$$ for each $i$;

- for each $h \in N$ a representation
  $$h = \sum_{i} a_i \lambda_i \ast g_{\ell_i} \ast b_\rho_i : a_i, b_\rho_i \in R \setminus \{0\}, \lambda_i, \rho_i \in \mathcal{T}, g_{\ell_i} \in B,$$
  is called a **bilateral standard representation** in $R$ in terms of $B$ iff
  $$\nu(h) \geq \nu(\lambda_i \ast g_{\ell_i} \ast \rho_i) = \lambda_i \circ \nu(g_{\ell_i}) \circ \rho_i$$ for each $i$;
for each \( h \in \mathbb{N} \) a representation

\[
h = \sum_i a_i g_{\ell_i} \ast \rho_{i} : a_i \in R \setminus \{0\}, \rho_i \in T, g_{\ell_i} \in B,
\]

is called a restricted standard representation in R in terms of B iff

\[
v(h) \geq v(g_{\ell_i} \ast \rho_i) = v(g_{\ell_i}) \circ \rho_i, \text{ for each } i;
\]

- if \( u \in \ker(s) \) is \( T^{(m)} \)-homogeneous and \( U \in \ker(\otimes) \) is such that \( u = \mathcal{L}(U) \), we say that \( u \) lifts to \( U \), or \( U \) is a lifting of \( u \), or simply \( u \) has a lifting;

- a (left, right, bilateral, restricted) Gebauer–Möller set for \( B \) is any \( T^{(m)} \)-homogeneous basis of \( \ker(s) \);

- for each \( T^{(m)} \)-homogeneous element \( \sigma \in R^u \), we say that \( \mathcal{E}_L(\sigma) \) has a left quasi-Gröbner representation in terms of \( B \) if it can be written as \( \mathcal{E}_L(\sigma) = \sum_{i=1}^u l_i \ast g_i \) with \( v(\sigma) > T(l_i \ast g_i) = T(l_i) \circ T(g_i) \) for each \( i \).

- for each \( T^{(m)} \)-homogeneous element \( \sigma \in R^u \), we say that \( \mathcal{E}_R(\sigma) \) has a right quasi-Gröbner representation in terms of \( B \) if it can be written as \( \mathcal{E}_R(\sigma) = \sum_{i=1}^u g_i \ast r_i \) with \( v(\sigma) > T(g_i \ast r_i) = T(g_i) \circ T(r_i) \) for each \( i \).

- for each \( T^{(m)} \)-homogeneous element \( \sigma \in (R \otimes_R R^{op})^u \), we say that \( \mathcal{E}_2(\sigma) \) has a bilateral quasi-Gröbner representation in terms of \( B \) if it can be written as

\[
\mathcal{E}_2(\sigma) = \sum_i a_i l_i \ast g_i \ast b_i \rho_i : a_i, b_i \in R \setminus \{0\}, l_i, \rho_i \in T, g_i, b_i \in B
\]

with \( v(\sigma) > l_i \circ T(g_i) \circ \rho_i \) for each \( i \).

- for each \( T^{(m)} \)-homogeneous element \( \sigma \in (R \otimes_R R^{op})^u \), we say that \( \mathcal{E}_W(\sigma) \) has a restricted quasi-Gröbner representation in terms of \( B \) if it can be written as

\[
\mathcal{E}_W(\sigma) = \sum_i a_i l_i \ast g_i \ast \rho_i : a_i \in R \setminus \{0\}, l_i, \rho_i \in T, g_i \in B
\]

with \( v(\sigma) > T(g_i) \circ \rho_i \) for each \( i \).

\[\square\]

Remark 34. Note that each left Gröbner representation of \( \mathcal{E}_L(\sigma) \) in terms of \( B \) gives also a left quasi-Gröbner representation since \( T(l_i) \circ T(g_i) \leq T(\mathcal{E}_L(\sigma)) \,< v(\sigma) \); on the other side, a left quasi-Gröbner representation grants only \( T(l_i) \circ T(g_i) \,< v(\sigma) \) but not necessarily \( T(l_i) \circ T(g_i) \,\leq T(\mathcal{E}_L(\sigma)) \), since in principle we could have \( T(\mathcal{E}_L(\sigma)) \,< T(l_i) \circ T(g_i) < v(\sigma) \) so that we don’t necessarily obtain a left Gröbner representation of the S-polynomial \( \mathcal{E}_L(\sigma) \).

This relaxation was introduced by Gebauer and Möller in their reformulation of Buchberger Theory for polynomial rings over a field [19]; in that setting, it allowed to better remove useless \( S \)-pairs and thus granted a more efficient reformulation of the algorithm; in the more general setting we are considering now, viz polynomials over rings, it becomes essential also for a smooth reformulation of the theory.

\[\square\]
Remark 35. Observe that if \( \sigma := \sum_{j=1}^{u} h_j e_j \in \ker(\mathcal{E}) \) then denoting
\[
\delta \epsilon := v(\sigma) \quad \text{and} \quad H := \left\{ j, 1 \leq j \leq u : T(h_j) \circ T(g_j) = \delta \epsilon \right\},
\]
its leading form \( L_L(\sigma) := \sum_{j=1}^{u} d_j \lambda_j e_j \in S^u \) is \( T^{(m)} \)-homogeneous of \( T^{(m)} \)-degree \( v(\sigma) := \delta \epsilon \in T^{(m)} \), satisfies
\[
- 0 \neq d_j \iff j \in H \quad \text{and} \quad M(h_j) = d_j \lambda_j,
- \sum_{j=1}^{u} d_j \lambda_j * M(g_j) = \sum_{j \in H} (d_j \lambda_j * (c_j \tau_j e_j)) = \left( \sum_{j \in H} \left( d_j \alpha_j (c_j) \cdot (\lambda_j \tau_j) \right) \right) \epsilon = 0,
- \sum_{j \in H} d_j \alpha_j (lc(g_j)) = 0 \quad \text{and} \quad \lambda_j \circ T(g_j) = \delta \epsilon \quad \text{for each} \quad j \in H,
- \epsilon = e_j \quad \text{for each} \quad j \in H,
\]
and belongs to \( \ker(\mathcal{S}_L) \).

Adapting Remarks 34 and 35 as done for Definition 33, one can obtain the analogous remarks for the right, bilateral and restricted case.

**Theorem 36** (Möller-Pritchard; Lifting Theorem). [35]

With the present notation and denoting \( \mathfrak{M}(F) \) any Gebauer–Möller set for \( F \subset R \), the following conditions are equivalent:

1. \( F \) is a Gröbner basis of \( \mathfrak{I}(F) \);
2. \( f \in \mathfrak{I}(F) \iff f \) has a Gröbner representation in terms of \( F \);
3. for each \( \sigma \in \mathfrak{M}(F) \), the S-polynomial \( \mathcal{E}(\sigma) \) has a quasi-Gröbner representation;
4. each \( \tau^{(m)} \)-homogeneous element \( u \in \ker(\tau) \) has a lifting \( \text{lift}(u) \);
5. each \( \tau^{(m)} \)-homogeneous element \( u \in \ker(\tau) \) has a lifting \( \text{lift}(u) \).

**Proof.**

We prove the statement only in the bilateral case, leaving to the reader the adaptations to the right, left and restricted cases.

(1) \( \implies \) (2) Let \( f \in \mathfrak{I}(F) \); by assumption
\[
M(f) = \sum_{i=1}^{u} a_i \lambda_i * M(g_{\ell_i}) * b_{\rho_i}
\]
where \( \sum_{i=1}^{u} a_i \lambda_i e_i b_{\rho_i} \in (\mathcal{S} \otimes \mathbb{R})^{(m)} \) is \( T^{(m)} \)-homogeneous of \( T^{(m)} \)-degree \( T(f) \).
Therefore \( g := f - \sum_{i=1}^{u} a_i \lambda_i * g_{\ell_i} * b_{\rho_i} \in \mathfrak{I}(F) \) and \( T(g) < T(f) \).

Thus, the claim follows by induction since \( < \) is a well-ordering.

(2) \( \implies \) (3) \( \mathcal{E}(\sigma) \in \mathfrak{I}(F) \) and \( T(\mathcal{E}(\sigma)) < v(\sigma) \).
Let

\[ \varepsilon_2(\sigma) = \sum_{i=1}^{\mu} a_i \lambda_i \star g_{\ell_i} \star b_i \rho_i, \quad \nu(\sigma) > \lambda_i \circ \tau_{\ell_i} \circ \rho_i e_{h_i} \]

be a bilateral quasi-Gröbner representation in terms of \( F \); then

\[ \text{lift}(\sigma) := \sigma - \sum_{i=1}^{\mu} a_i \lambda_i e_{\ell_i} b_i \rho_i \]

is the required lifting of \( \sigma \).

Let \( u := \sum_i a_i \lambda_i e_{\ell_i} b_i \rho_i \in (S \otimes_R S^{op})^u \), \( \lambda_i \circ \tau_{\ell_i} \circ \rho_i e_{h_i} = \nu(u) \), be a \( T^{(m)} \)-homogeneous element in \( \ker(\varepsilon_2) \) of \( T^{(m)} \)-degree \( \nu(u) \).

Then there are \( \lambda_{\sigma}, \rho_{\sigma} \in T, a_{\sigma}, b_{\sigma} \in R \setminus \{0\} \), for which

\[ u = \sum_{\sigma \in \mathfrak{H}(F)} a_{\sigma} \lambda_{\sigma} \star \sigma \star b_{\sigma} \rho_{\sigma}, \quad \lambda_{\sigma} \circ \rho_{\sigma} = \nu(u). \]

For each \( \sigma \in \mathfrak{H}(F) \) denote

\[ \tilde{\sigma} := \sigma - \text{lift}(\sigma) = L_2(\text{lift}(\sigma)) - \text{lift}(\sigma) := \sum_{i=1}^{\mu} a_i \lambda_i e_{\ell_i} b_i \rho_i \in (R \otimes_R R^{op})^u \]

and remark that \( \lambda_{\sigma} \circ \tau_{\ell_{\sigma}} \circ \rho_{\sigma} e_{h_{\sigma}} \leq \nu(\tilde{\sigma}) < \nu(\sigma) \) and \( \varepsilon_2(\tilde{\sigma}) = \varepsilon_2(\sigma) \).

It is sufficient to define

\[ \text{lift}(u) := \sum_{\sigma \in \mathfrak{H}(F)} a_{\sigma} \lambda_{\sigma} \star \text{lift}(\sigma) \star b_{\sigma} \rho_{\sigma}, \quad \text{and } \tilde{u} := \sum_{\sigma \in \mathfrak{H}(F)} a_{\sigma} \lambda_{\sigma} \star \tilde{\sigma} \star b_{\sigma} \rho_{\sigma} \]

to obtain

\[ \text{lift}(u) = u - \tilde{u}, \quad \varepsilon_2(\tilde{u}) = \varepsilon_2(u), \quad \varepsilon_2(\text{lift}(u)) = 0. \]

Let \( g \in \mathfrak{H}(F) \), so that there are \( \lambda_i, \rho_i \in T, a_i, b_i \in R \setminus \{0\}, 1 \leq \ell_i \leq u, \) such that \( \sigma_1 := \sum_{i=1}^{\mu} a_i \lambda_i e_{\ell_i} b_i \rho_i \in (R \otimes_R R^{op})^u \) satisfies

\[ g = \varepsilon_2(\sigma_1) = \sum_{i=1}^{\mu} a_i \lambda_i \star g_{\ell_i} \star b_i \rho_i. \]

Denoting \( H := \{ i : \lambda_i \circ T(\ell_i) \circ \rho_i = \lambda_i \circ \tau_{\ell_i} \circ \rho_i e_{h_i} = \nu(\sigma_1) \} \), then either

\[ -\nu(\sigma_1) = T(g) \text{ so that, for each } i \in H, \quad M(a_i \lambda_i \star M(g_{\ell_i} \star b_i \rho_i) = a_i \lambda_i \star M(g_{\ell_i}) \star b_i \rho_i \]
and

\[ M(g) = \sum_{i \in H} a_i \lambda_i \star M(g_{\ell_i}) \star b_i \rho_i \in M([\varepsilon_2(M[F])], \]

and we are through, or
Theorem 37 (Janet—Schreyer). \[ \{20, 47, 48\]  

With the same notation the equivalent conditions (1-5) imply that

- \( T(g) < v(\sigma_1) \), in which case \( 0 = \sum_{i \in H} a_i \lambda_i = M(g_{\ell_i}) \cdot b_i \rho_i \) is the \( T^{(m)} \)-homogeneous element \( \mathcal{L}_2(\sigma_1) \in \ker(\zeta_2) \) has a lifting

\[
U := \mathcal{L}_2(\sigma_1) - \sum_{j=1}^{v} a_j \lambda_j \epsilon_j \cdot b_j \rho_j \in (R \otimes_R R^{op})^n
\]

with

\[
\sum_{j=1}^{v} a_j \lambda_j \ast b_j \rho_j = \sum_{i \in H} a_i \lambda_i \ast g_{\ell_i} \ast b_i \rho_i \text{ and } \lambda_j \circ \tau_{\ell_i} \circ \rho_i \epsilon_{\ell_i} < v(\sigma_1)
\]

so that \( g = \zeta_2(\sigma_2) \) and \( v(\sigma_2) < v(\sigma_1) \) holds for

\[
\sigma_2 := \sum_{i \in H} a_i \lambda_i \epsilon_i \cdot b_i \rho_i + \sum_{j=1}^{v} a_j \lambda_j \epsilon_j \cdot b_j \rho_j \in (R \otimes_R R^{op})^n
\]

and the claim follows by the well-orderedness of \( < \).

\( \square \)

\textbf{Theorem 37} (Janet—Schreyer). \[ \{20, 47, 48\]  

With the same notation the equivalent conditions (1-5) imply that

- \( (\text{lift}(\sigma) : \sigma \in \mathfrak{M}(F)) \) is a standard basis of \( \ker(\zeta) \).

\textbf{Proof}. \( (4) \implies (6) \) Let \( \sigma_1 := \sum_{i=1}^{\mu} a_i \lambda_i \epsilon_i \cdot b_i \rho_i \in \ker(\zeta_2) \subset (R \otimes_R R^{op})^n \).

Denoting \( H := \{ i : \lambda_i \circ \tau_{\ell_i} \circ \rho_i \epsilon_{\ell_i} = v(\sigma_1) \} \), we have

\[
\mathcal{L}_2(\sigma_1) = \sum_{i \in H} a_i \lambda_i \epsilon_i \cdot b_i \rho_i \in \ker(\zeta_2)
\]

and there is a \( T^{(m)} \)-homogeneous representation

\[
\mathcal{L}_2(\sigma_1) = \sum_{\sigma \in \mathfrak{M}(F)} a_{\sigma} \lambda_{\sigma} \ast \sigma \ast b_{\sigma} \rho_{\sigma}, \lambda_{\sigma} \circ v(\sigma) \circ \rho = v(\sigma_1)
\]

with \( \lambda_{\sigma}, \rho_{\sigma} \in T, a_{\sigma}, b_{\sigma} \in R \setminus \{0\} \).

Then

\[
\sigma_2 := \sigma_1 - \sum_{\sigma \in \mathfrak{M}(F)} a_{\sigma} \lambda_{\sigma} \ast \text{lift}(\sigma) \ast b_{\sigma} \rho_{\sigma}
\]

\[
= \sigma_1 - \sum_{\sigma \in \mathfrak{M}(F)} a_{\sigma} \lambda_{\sigma} \ast (\sigma - \bar{\sigma}) \ast b_{\sigma} \rho_{\sigma}
\]

\[
= \sigma_1 - \mathcal{L}_2(\sigma_1) + \sum_{\sigma \in \mathfrak{M}(F)} a_{\sigma} \lambda_{\sigma} \ast \bar{\sigma} \ast b_{\sigma} \rho_{\sigma}
\]

\[
= \sum_{i \in H} a_i \lambda_i \epsilon_i \cdot b_i \rho_i
\]

\[
+ \sum_{\sigma \in \mathfrak{M}(F)} \sum_{i=1}^{\mu_{\sigma}} \left( (a_{\sigma} \lambda_{\sigma}(a_{\sigma}) \cdot (\lambda_{\sigma} \circ \lambda_{\sigma}(a_{\sigma})) \epsilon_{\ell_i} \cdot (b_{\sigma} \circ \rho_{\sigma}(b_{\sigma}) \cdot \rho_{\sigma}) \right)
\]

32
satisfies both \( \sigma_2 \in \ker(\Xi_2) \) and \( v(\sigma_2) < v(\sigma_1) \); thus the claim follows by induction.

\[ \square \]

**Example 38.** Let us consider the ring of Example 17 and three elements \( f_1, f_2, f_3 \in \mathbb{R} \) with
\[
M(f_1) = (5x - 1)Y_1^2Y_2^2, M(f_2) = (5x - 1)Y_2^2Y_3^2, M(f_3) = (5x - 1)Y_1^2Y_2^2Y_3.
\]

Under the natural \( \mathcal{T} \)-pseudoevaluation on \( \mathbb{R}^3 \), an element
\[
\sigma := (\alpha Y_1^{\alpha_1}Y_2^{\alpha_2}Y_3^{\alpha_3}, \beta Y_1^{\beta_1}Y_2^{\beta_2}Y_3^{\beta_3}, \gamma Y_1^{\gamma_1}Y_2^{\gamma_2}Y_3^{\gamma_3}) \in S^3
\]
(7)
is homogeneous of \( \mathcal{T} \)-degree \( y^{\alpha_2 + 3}Y_2^{\beta_2 + 2}Y_3^{\gamma_2} \) iff
\[
\alpha_1 - 1 = \beta_1 = \gamma_1 = \alpha, \alpha_2 = \beta_2 - 1 = \gamma_2 = \beta, \alpha_3 = \beta_3 = \gamma_3 - 1 = c.
\]

Let us now specialize ourselves to the case \( a = b = c = 0 \) and consider the \( \mathbb{Z}[x] \)-module of the homogeneous syzygies of \( \mathcal{T} \)-degree \( Y_1^2Y_2^2Y_3^2 \); setting \( y = 5x \), (7) is a syzygy in \( \ker(s_L) \) iff
\[
0 = s_L(\sigma)
= \alpha Y_1 \ast M(f_1) + \beta Y_2 \ast M(f_2) + \gamma Y_3 \ast M(f_3)
= (\alpha(y^2 - 1) + \beta(y^3 - 1) + \gamma(y^4 - 1)) Y_1^2Y_2^2Y_3^2.
\]

A minimal left Gebauer-Möller set consists of
\[
\sigma_1 := (-(y^2 + y + 1))Y_1, (y + 1)Y_2, 0) \text{ and } \sigma_2 := (-(y^2 + 1))Y_1, 0, Y_3).
\]

In fact a generic syzygy (7) satisfies
\[
\alpha(y^2 + 1) + \beta(y^3 + y + 1) + \gamma(y^2 + 1)(y + 1) = 0
\]
so that \( (y + 1) \mid \beta \) and setting \( \beta = (y + 1)\delta \) we have \( \alpha = -\delta(y^2 + y + 1) - \gamma(y^3 + 1) \) whence
\[
\sigma := \left(\left(-\delta(y^2 + y + 1) - \gamma(y^2 + 1)\right)Y_1, (y + 1)\delta Y_2, \gamma Y_3\right) = \delta \sigma_1 + \gamma \sigma_2.
\]

**Remark 39.** We can consider also the homogeneous syzygy of \( \mathcal{T} \)-degree \( Y_1^2Y_2^2Y_3^2 \)
\[
\sigma_3 := (0, -(y^2 + 1)(y + 1)Y_2, (y^2 + y + 1)Y_3) = -(y^2 + 1)\sigma_1 + (y^2 + y + 1)\sigma_2.
\]

Moreover, since
\[
1 = (y^2 + y + 1) - y(y + 1) = (y^3 + y^2 + y + 1) - y(y^2 + y + 1)
\]
setting
\[
\varsigma_A := (-yY_1, Y_2, 0) \in S^3, \varsigma_B := (0, -yY_2, Y_3) \in S^3
\]
we have
\[
s_L(\varsigma_A) = s_L(\varsigma_B) = (y - 1)Y_1^2Y_2^2Y_3^2;
\]
note that
\[
\varsigma_A - \varsigma_B := (-yY_1, (y + 1)Y_2, -Y_3) = \sigma_1 - \sigma_2 \in \ker(s_L).
\]

\[ \square \]
Example 38 (cont.). Setting now $\tau := y_1^2 y_2 y_3^2$ and $z := y_2^3 y_4^2$, for the syzygy (7) we have

$$0 = s_\ell(\sigma)$$

$$= \alpha \tau y_1 * \text{M}(f_1) + \beta \tau y_2 * \text{M}(f_2) + \gamma \tau y_3 * \text{M}(f_3)$$

$$= \left(\alpha \tau * (y^2 - 1) + \beta \tau * (y^3 - 1) + \gamma \tau * (y^4 - 1)\right) y_1^2 y_2^2 y_3^2.$$  

whence

$$\alpha = -\delta(z^2 + z + 1) - \gamma(z^2 + 1), \quad \beta = (z + 1)\delta$$

and

$$\sigma := \delta \tau * \sigma_1 + \gamma \tau * \sigma_2.$$  

Thus, $\{\sigma_1, \sigma_2\}$ is a minimal basis of $\ker(s_\ell)$.

6 Gröbner basis Computation for Multivariate Ore Extensions of Zacharias Domains

We recall the definition of Zacharias ring [54], [31, §26.1], [32].

Definition 40. A ring $R$ with identity is called a (left) Zacharias ring if it satisfies the following properties:

(a). $R$ is a noetherian ring;

(b). there is an algorithm which, for each $c \in R^m$, $C := \{c_1, \ldots, c_t\} \subset R^m \setminus \{0\}$, allows
to decide whether $c \in I_\ell(C)$ in which case it produces elements $d_i \in R : c = \sum_{i=1}^t d_i c_i$;

(c). there is an algorithm which, given $\{c_1, \ldots, c_t\} \subset R^m \setminus \{0\}$, computes a finite set of
generators for the left syzygy $R$-module \(\{(d_1, \ldots, d_t) \in R^t : \sum_{i=1}^t d_i c_i = 0\}\).

Note that [35] for a ring $R$ with identity which satisfies (a) and (b), (c) is equivalent
to

(d). there is an algorithm which, given $\{c_1, \ldots, c_s\} \subset R^m \setminus \{0\}$, computes a finite basis
of the ideal

$$I_\ell(\{c_i : 1 \leq i < s\}) : I_\ell(c_s).$$

If $R$ has canonical representatives, we improve the computational assumptions of
Zacharias rings, requiring also the following property:

(e). there is an algorithm which, given an element $c \in R^m$ and a left module $J \subset R^m$,
computes the unique canonical representative $\text{Rep}(c, J)$. $\Box$

If $R$ is a left Zacharias domain, the three algorithms proposed by Möller [35] for
computing Gröbner bases in the polynomial ring over $R$ can be easily adapted to multi-
variate Ore extensions of Zacharias domains, provided that each $\alpha_i$, and therefore each
$\alpha_\tau$, is an automorphism.
6.1 First algorithm

Still considering a finite basis

\[ F := \{g_1, \ldots, g_u\} \subset \mathbb{R}^m, \quad g_i = M(g_i) - p_i =: c_i \tau_i e_i - p_i, \]

of the module \( M := I_L(F) \) and denoting

\[ \xi(F) := \{i_1, i_2, \ldots, i_r \} \subseteq \{1, \ldots, u\} : l_{i_1} = \cdots = l_{i_r} \];

\[ \text{– for each } H := \{i_1, i_2, \ldots, i_r\} \in \xi(F), \]

\[ \begin{align*}
&\varepsilon_H := e_{i_1} = \cdots = e_{i_r}, \\
&\tau_H := \text{lcm} (\tau_i : i \in H), \\
&\text{– for each } I \subset H, \\
&\quad \tau_{HI} := \frac{\tau_H}{\tau_I}, \\
&\quad \alpha_{HI} : R \to R \text{ the morphism } \alpha_{HI},^3 \\
&\quad T(H) := \tau_{HI} \varepsilon_H, \\
\end{align*} \]

and, if \( R \) is a PID,

\[ \begin{align*}
&\text{– } c_H := \text{lcm}(\alpha_{HI}(c_i) : i \in H), \\
&\text{– } \mu(H) := c_H \tau_H \text{ and } \\
&\quad M(H) = c_H T(H) = c_H \tau_H \varepsilon_H = \mu(H) \varepsilon_H; \\
&\text{– } T := \{T(H) : H \in \xi(F)\}; \\
&\text{– for any } m = \delta \varepsilon \in T, \\
&\quad \text{– for each } i, 1 \leq i \leq u, t_i(m) := \left\{ \frac{\delta}{\tau_i} \quad \text{if } T(g_i) \mid m, \\
&\quad \quad 1 \quad \text{otherwise}; \\
&\quad v(m) = (v(m)_1, \ldots, v(m)_u) \in \mathbb{R}^u \text{ the vector such that} \\
&\quad v(m)_i := \begin{cases} \\
\alpha_{i(c_i)}(\text{lcm}(g_i)) & \text{if } T(g_i) \mid m, \\
0 & \text{otherwise}; \\
\end{cases} \\
&\quad C(m) \subset \mathbb{R}^u \text{ a finite basis of the syzygy module} \\
&\quad \text{Syz}_L(v(m)_1, \ldots, v(m)_u) := \left\{ (d_1, \ldots, d_u) \in \mathbb{R}^u : \sum_{i=1}^u d_i v(m)_i = 0 \right\}; \\
&\quad S(m) := \{(d_1 t_1(m), \ldots, d_u t_u(m)) : (d_1, \ldots, d_u) \in C(m)\}; \\
&\quad S(F) := \bigcup_{m \in T} S(m); \\
&\quad S'(F) \subset S(F) \text{ any subset satisfying} \\
\end{align*} \]

\(^3\text{If } I = \{i\} \text{ we will write } \alpha_{Ii} \text{ and } \tau_{Ii} \text{ instead of } \alpha_{HI} \text{ and } \tau_{HI}.\)

– for each \( \sigma \in S(F) \setminus S'(F) \) exist \( \sigma_j \in S'(F), d_j \in R, \tau_j \in T \), such that \( \sigma = \sum_j d_j \tau_j \ast \sigma_j \);

– \( R(F) := \{ \sum_i m_i \ast g_i : (m_1, \ldots, m_n) \in S'(F) \} \), we have that (cf. [35], [31, Theorem 26.1.4])

**Lemma 41.** \( S(F) \) is a left Gebauer–Möller set for \( F \).

**Proof.** Let us consider a generic \( T^{(m)} \)-homogeneous element

\[
\sigma := \sum_{i=1}^u a_i \lambda_i e_i \in \mathbb{R}^u \setminus \{0\},
\]

with \( a_i \in R, \lambda_i \in T, \nu(\sigma) := \tau \epsilon \), and \( a_i \neq 0 \implies \lambda_i \tau_i = \tau, \epsilon = e_i \), and assume that it is a left syzygy in \( \ker(s_c) \).

Denoting \( I := \{ i \leq u : a_i \neq 0 \} \) and setting \( m := \delta \epsilon := \lcm[T(g_i) : i \in I] \mid \nu(\sigma) \), there is \( \nu \in T : \nu \delta = \tau \). With the present notation we also have \( \delta = t_i(m) \tau_i \); thus \( \nu t_i(m) \tau_i = \nu \delta = \lambda_i \tau_i \) and \( \lambda_i = \nu t_i(m) \). We also have

\[
0 = \sum_{i=1}^u a_i \lambda_i (\lcm(g_i))
\]

so that

\[
0 = \alpha^{-1}_\nu \left( \sum_{i=1}^u a_i \lambda_i (\lcm(g_i)) \right) = \sum_{i=1}^u \alpha^{-1}_\nu(a_i) \lambda_i (\lcm(g_i))
\]

and \( (\alpha^{-1}_\nu(a_1), \ldots, \alpha^{-1}_\nu(a_u)) \in \text{Syz}_T(\nu(m_1), \ldots, \nu(m_n)) \).

Therefore, if we enumerate as

\[
(d_{11}, \ldots, d_{1u}), \ldots, (d_{v1}, \ldots, d_{vu})
\]

the elements of a basis of \( C(m) \) and we denote \( s_j := \sum_{i=1}^u d_j t_i(m) e_i, 1 \leq j \leq v \), those of \( S(m), \) we have \( (\alpha^{-1}_\nu(a_1), \ldots, \alpha^{-1}_\nu(a_u)) = \sum_{j=1}^v b_j (d_{j1}, \ldots, d_{ju}) \) for suitable \( b_j \in R \) and

\[
\sigma = \sum_{i=1}^u a_i \lambda_i e_i
\]

\[
= \sum_{i=1}^u a_i \nu t_i(m) e_i
\]

\[
= \sum_{i=1}^u \nu \ast \alpha^{-1}_\nu(a_i) t_i(m) e_i
\]

\[
= \nu \ast \sum_{i=1}^u \sum_{j=1}^v b_j d_j t_i(m) e_i
\]

\[
= \sum_{j=1}^v \alpha_v(b_j) \nu \ast \left( \sum_{i=1}^u d_j t_i(m) e_i \right)
\]

\[
= \sum_{j=1}^v \alpha_v(b_j) \nu \ast s_j.
\]
Corollary 42. The following holds:

1. $S'(F)$ is a left Gebauer–Möller set for $F$.

2. $F$ is a left Gröbner basis of the module it generates iff each $h \in R(F)$ has a left Gröbner representation in terms of $F$.

Example 43. If we consider the ring of Example 17 as a left $\mathbb{Z}[x]$-module endowed with the $\Gamma$-pseudoevaluation, $\Gamma = \{x^a y^b : (a_1, a_2, a_3) \in \mathbb{N}^3\}$, we obtain a similar solution as the one described in Example 38.

Expressing each $M(f_i)$ as $M(f_i) = \text{lc}(f_i)T(f_i)$, according Zacharias approach we need to compute a syzygy basis in $\mathbb{Z}[x]$ among $\alpha_1(\text{lc}(f_i)) = (y^2 - 1)$, $\alpha_2(\text{lc}(f_i)) = (y^3 - 1)$ and $\alpha_3(\text{lc}(f_i)) = (y^4 - 1)$; the natural solutions $(-y^2 + y + 1), (y + 1), 0$, $(-y^2 - 1), 0, 1$ produce $\sigma_1$ and $\sigma_2$.

Example 44. Let us now specialize the ring of Example 14 to the case

$n = 3, e_1 = e_2 = e_3 = 1, c_1 = 20, c_2 = 6, c_3 = 15,$

and let us consider four elements $f_1, f_2, f_3, f_4 \in R$ with

$M(f_1) = xy_1y_2^2y_3^3, M(f_2) = x^2y_2y_3^2, M(f_3) = x^2y_1y_2^3y_3^2, M(f_4) = x^6y_2^2y_3^3.$

We have

$T = \{x^2y_1y_2^3y_3^3, y_1^2y_2y_3, y_1^2y_2^2y_3^2, y_1^2y_2^3y_3, y_1^2y_3, y_1y_2^3y_3^2\},$

and

| $m$         | $t_1(m), \ldots, t_4(m)$ | $\nu(m)$ |
|-------------|---------------------------|-----------|
| $y_1^2y_2^3$ | (1, 0, 0, 0)              | (x, 0, 0, 0) |
| $y_1^2y_2y_3^2$ | (0, 1, 0, 0)         | (0, x^2, 0, 0) |
| $y_1^2y_2^2y_3^2$ | (0, 0, 1, 0)       | (0, 0, x, 0) |
| $y_1^2y_2^3y_3$ | (0, 0, 1, 0)          | (0, 0, 0, 0) |
| $y_1^2y_3^2y_2^2$ | ($y_1^2$, $y_2^2$, $y_3$) | (20x, 6x^3, 15x, 6x) |

Denoting

$b(1, 3) := (-3y_1, 0, 4y_3, 0),$

$b(2, 4) := (0, -y_2, 0, 6x),$

$b(3, 4) := (0, 0, -2y_3, 0, 5y_2)$

we have $S(Y_1^2Y_2^3Y_3^2) = \{b(2, 4)\}$ and, since

$y_2 \ast b(2, 4) = (0, -y_2, 0, 6x - 2y_2) = (0, -y_2^3, 0, 6x)$

we can take $S(Y_1^2Y_2^3Y_3^2) = \{b(1, 3), y_2 \ast b(2, 4), b(3, 4)\}$; thus

$S' := \{b(1, 3), b(2, 4), b(3, 4)\}$

is the required Gebauer–Möller set.

□
Möller [35] proposed also an (essentially equivalent) alternative computation: for any $s, 1 \leq s \leq u$, let us consider the syzygy module

$$S_s := \left\{ (h_1, \ldots, h_s) : \sum_{i=1}^{s} h_i \star M(g_i) = 0 \right\} \subset \mathbb{R}^s$$

and let us compute $S(F) = S_u$ by inductively extending $S_{s-1}$ to $S_s$, the inductive seed being $S_1 = \emptyset$.

A direct application of the property (d) of a Zacharias ring allows to compute a Gebauer-Möller set via

**Definition 45.** A subset $H \subset \{1, \ldots, s\} \cap \tilde{S}(F), s \leq u$, is said to be

- maximal for a term $\delta \epsilon \in T^{(m)}$ if $H = \{ i, 1 \leq i \leq s : \tau_i \mid \delta, e_i = \epsilon \}$,
- basic if $s \in H$ and $H$ is maximal for $T(H)$.

For any $d_s \in \mathbb{R}^s((\alpha_{H,s}(c_i) : i \in H^s)) : \mathbb{R}^s(\alpha_{H,s}(c_i)))$, a syzygy associated to $H$ and $d_s$ is a $T^{(m)}$-homogeneous syzygy

$$\sum_{i \in H^s} d_i \frac{\tau_H}{\tau_i} e_i + d_s \frac{\tau_H}{\tau_s} e_s \in S_s$$

where $d_i \in R$ are suitable elements for which $d_i \alpha_{H,s}(c_i) = - \sum_{i \in H^s} d_i \alpha_{H,s}(c_i).$ \hfill $\square$

**Theorem 46 (Möller).** [35] With the present notation, denoting

- $\{A_1, \ldots, A_u\}$ a $T^{(m)}$-homogeneous basis of $S_{s-1}$,
- $\mathcal{H}$ the set of all basic subsets $H \subset \{1, \ldots, s\} \cap \tilde{S}(F)$,
- $\{d_1H, \ldots, d_{r_H}H\}$ a basis of the ideal $\mathbb{R}^s((\alpha_{H,s}(c_i) s.t. i \in H^s)) : \mathbb{R}^s(\alpha_{H,s}(c_i))$ for each basic subset $H \in \mathcal{H}$,
- $D_{jH} \in \mathbb{R}^s$ a syzygy associated to $H$ and $d_{jH}$, for each basic subset $H \in \mathcal{H}$ and each $j, 1 \leq j \leq r_H$,

the set $\{A_1, \ldots, A_u\} \cup \{D_{jH} : H \in \mathcal{H}, 1 \leq j \leq r_H\}$ is a $T^{(m)}$-homogeneous basis of $S_s$.

**Proof.** Let $S := (d_1l_1, \ldots, d_sl_s) \in S_s, d_s \neq 0$, be a $T^{(m)}$-homogeneous element of $T^{(m)}$-degree $\delta \epsilon$ and let

$$K := \{ i, 1 \leq i \leq s : d_i \neq 0 \};$$

since by $T^{(m)}$-homogeneity, $\tau_i \mid \delta$ and $e_i = \epsilon$ for each $i \in K$, we have $T(K) \mid \delta \epsilon$; we also have $d_i = 0$ for each $i \notin K$ and $\lambda_i \tau_i = \delta, e_i = \epsilon$ for each $i \in K$. 

38
For the set $H := \{i, 1 \leq i \leq s : \tau_i, e_i = \varepsilon_i\}$ clearly we have $\tau_H | \tau_K$ and $K \subseteq H$ so that $\tau_H | \tau_K | \delta$; we also have $\varepsilon_H = \varepsilon_K = \varepsilon$. Moreover $d_i \neq 0$ implies $s \in K \subseteq H$ so that $H$ is basic. Since $(d_1, \ldots, d_s) \in S_s$, setting $\nu := \frac{d}{\tau_H}$, we have

$$0 = \sum_{i=1}^{s} d_i \alpha_i * M(g_i) = \sum_{i \in H} d_i \frac{\delta}{\tau_i} = c_i \tau_i \epsilon = \left(\sum_{i \in H} d_i \alpha_i(c_i)\right) \delta \epsilon$$

so that $\sum_{i \in H} d_i \alpha_i(c_i) = 0$, $\sum_{i \in H} \alpha^{-1}_i(d_i) \alpha H(c_i) = 0$, whence

$$\alpha^{-1}_i(d_i) \alpha H(c_i) \epsilon = \sum_{i \in H} (\alpha H(c_i) : i \in H^\times) \epsilon = \sum_{i \in H} (\alpha H(c_i) : i \in H^\times) \epsilon = \sum_{i \in H} (\alpha H(c_i)).$$

Therefore, for suitable $u_i$, $\alpha^{-1}_i(d_i) = \sum_{j=1}^{u_i} u_i d_j H$ and $S - \sum_{j=1}^{u_i} \alpha_i(u_i) v * D_j H \in S_{s-1}$. □

**Example 47.** If we consider the ring of Example 17 as a left $\mathbb{Z}[x]$-module endowed with the $\Gamma$-pseudovaluation, $\Gamma = \{y^a x^b y^c : (a, b, c) \in \mathbb{N}^3\}$, we obtain a similar solution as the one described in Example 38.

Expressing each $M(f_i)$ as $M(f_i) = \text{l.c.}(f_i) T(f_i)$, according Zacharias approach we need to compute a syzygy bases in $\mathbb{Z}[x]$ among $\alpha Y_i (\text{l.c.}(f_i)) = (y^2 - 1)$, $\alpha Y_i (\text{l.c.}(f_2)) = (y^3 - 1)$ and $\alpha Y_i (\text{l.c.}(f_3)) = (y^4 - 1)$; the natural solutions $(-y^2 + y + 1), (y + 1), 0$, $(-y^2 + 1), 0, 1$ produce $\alpha_1$ and $\alpha_2$.

**Example 48.** In Example 44, the basic elements are the following:

| $H$     | $T(H)$     | $f_H$ |
|---------|------------|-------|
| $s = 1$ | $Y_1 Y_2 Y_3^2$ | $f_1$ |
| $s = 2$ | $Y_1 Y_2 Y_3^2$ | $f_1$ |
|         | $Y_1 Y_2 Y_3^4$ | $f_1$ |
|         | $Y_1 Y_2 Y_3^4$ | $f_1$ |
| $s = 3$ | $Y_1 Y_2 Y_3^4$ | $f_1$ |
|         | $Y_1 Y_2 Y_3^4$ | $f_1$ |
|         | $Y_1 Y_2 Y_3^4$ | $f_1$ |
| $s = 4$ | $Y_1 Y_2 Y_3^4$ | $f_1$ |
|         | $Y_1 Y_2 Y_3^4$ | $f_1$ |
|         | $Y_1 Y_2 Y_3^4$ | $f_1$ |
|         | $Y_1 Y_2 Y_3^4$ | $f_1$ |
|         | $Y_1 Y_2 Y_3^4$ | $f_1$ |

$\square$

**Corollary 49.** Assuming that the Zacharias domain $R$ is a principal ideal domain and
denoting\(^4\), for each \(i, j, 1 \leq i < j \leq u\), \(e_i = e_j\),

\[
\begin{align*}
\mathbf{b}((i, j)) & := \frac{\lcm (\alpha_{i,j}(c_i), \alpha_{i,j}(c_j))}{\alpha_{i,j}(c_i)} \frac{\lcm (\tau_i, \tau_j)}{\tau_j} e_j \\
& \quad - \frac{\lcm (\alpha_{i,j}(c_i), \alpha_{i,j}(c_j))}{\alpha_{i,j}(c_i)} \frac{\lcm (\tau_i, \tau_j)}{\tau_i} e_i, \\
\mathbf{B}((i, j)) & := \frac{\lcm (\alpha_{i,j}(c_i), \alpha_{i,j}(c_j))}{\alpha_{i,j}(c_i)} \frac{\lcm (\tau_i, \tau_j)}{\tau_j} \star g_j \\
& \quad - \frac{\lcm (\alpha_{i,j}(c_i), \alpha_{i,j}(c_j))}{\alpha_{i,j}(c_i)} \frac{\lcm (\tau_i, \tau_j)}{\tau_i} \star g_i,
\end{align*}
\]

we have that \(\{\mathbf{b}((i, j)) : 1 \leq i < j \leq u, e_i = e_j\}\) is a left Gebauer–Möller set for \(F\), so that \(F\) is a left Gröbner basis of \(\mathcal{M}\) iff each \(\mathbf{B}((i, j)), 1 \leq i < j \leq u, e_i = e_j\), has a left weak Gröbner representation in terms of \(F\).

**Proof.** Since, for any basic subset \(H \subset \{1, \ldots, s\} \cap \delta(F)\) we have

\[
\mathbb{I}(\{\alpha_{i,j}(c_i) : i \in H\}) : \mathbb{I}(\{\alpha_{i,j}(c_i)\}) = \bigoplus \mathbb{I}(\{\alpha_{i,j}(c_i)\}) : \mathbb{I}(\{\alpha_{i,j}(c_i)\}) = \bigoplus \left( \frac{\lcm (\alpha_{i,j}(c_i), \alpha_{i,j}(c_i))}{\alpha_{i,j}(c_i)} \right)
\]

and \(\mathbf{b}((i, s))\) is the syzygy associated to \([i, s]\) and \(\frac{\lcm (\alpha_{i,j}(c_i), \alpha_{i,j}(c_i))}{\alpha_{i,j}(c_i)}\).

**Example 50.** In Example 44, we obtain the following redundant Gebauer–Möller set (see Example 63)

\[
\begin{array}{cccccc}
(i, j) & \lcm (\alpha_{i,j}(c_i), \alpha_{i,j}(c_j)) & \lcm (\tau_i, \tau_j) & b((i, j)) \\
(1, 2) & 6^4 \cdot 5x^2 & Y_2^3 Y_2^4 & (-2^3 Y_1, & 5^2, & 0, 0) \\
(1, 3) & 60x & Y_2^3 Y_2^4 & (-3 Y_1, & 0, & 4 Y_3, 0) \\
(2, 3) & 6^4 \cdot 5x^2 & Y_2^3 Y_2^4 & (0, & -5 Y_2, 3^2 Y_3, 0) \\
(1, 4) & 60x & Y_2^3 Y_2^4 & (-3 Y_1, & 0, & 0, 10 Y_2) \\
(2, 4) & 6^2 x^2 & Y_2^3 Y_2^4 & (0, & -Y_2, 0, 6^2 x) \\
(3, 4) & 30x & Y_2^3 Y_2^4 & (0, & 0, -2 Y_3, 5 Y_2) \\
\end{array}
\]

**Corollary 51.** Assuming that the Zacharias domain \(R\) is a principal ideal domain and that each \(\alpha_i\) is an automorphism denoting, for each \(i, j, 1 \leq i < j \leq u\), \(e_i = e_j\),

\[
\begin{align*}
\mathbf{b}((i, j)) & := e_i \alpha_{ij}^{-1} \left( \frac{\lcm (c_i, c_j)}{c_i} \right) \frac{\lcm (\tau_i, \tau_j)}{\tau_j} \quad e_j \alpha_{ij}^{-1} \left( \frac{\lcm (c_i, c_j)}{c_i} \right) \frac{\lcm (\tau_i, \tau_j)}{\tau_i} \\
\mathbf{B}((i, j)) & := g_i \star \alpha_{ij}^{-1} \left( \frac{\lcm (c_i, c_j)}{c_i} \right) \frac{\lcm (\tau_i, \tau_j)}{\tau_j} \quad g_j \star \alpha_{ij}^{-1} \left( \frac{\lcm (c_i, c_j)}{c_i} \right) \frac{\lcm (\tau_i, \tau_j)}{\tau_i}
\end{align*}
\]

\(^4\)Remember that \(\alpha_{i,j} = \alpha_i\) for \(\tau = \frac{\lcm (\tau_i, \tau_j)}{\tau_j}\).
we have that \( \{ b(i, j) : 1 \leq i < j \leq u, e_i = e_j \} \) is a right Gebauer–Möller set for \( F \), so that \( F \) is a right Gröbner basis of \( M \) iff each \( B(i, j) \), \( 1 \leq i < j \leq u, e_i = e_j \), has a right weak Gröbner representation in terms of \( F \). \( \square \)

### 6.3 Third algorithm: from weak to strong Gröbner basis

As regards strong Gröbner bases, we consider a left Zacharias PID. In this case, we have

**Definition 52.** A set \( C \subset \mathbb{R}^n \) is called a completion of \( F \), if, for each subset \( H \subset S(F) \) which is maximal for \( T(H) \), it contains an element \( f_H \in \mathbb{I}(F) \) which satisfies

1. \( T(f_H) = T(H) = \tau_H e_H \),
2. \( \text{lc}(f_H) = c_H = \gcd(\alpha_{H,i}(\text{lc}(g_i)) : i \in H) \),
3. \( f_H \) has a left Gröbner representation in terms of \( F \).

**Algorithm 53** (Möller). A completion of \( F \) can be inductively computed by mimicking the construction of Theorem 46 as follows: the result being trivial if \( \#F = 1 \), we can assume to have already obtained a completion \( C(F^x) \) of \( F^x = \{ g_1, \ldots, g_s \} \), \( s \leq u \); for each maximal subset \( H \subset \{ 1, \ldots, s \} \), if \( s \notin H \) we can take as \( f_H \) the corresponding element in \( C(F^x) \). If instead \( s \in H \), then \( H^x \) is maximal in \( F^x \) for \( T(H^x) \) and \( \tau_{H^x} | \tau_H \); thus there is a corresponding element \( f_{H^x} \) in \( C(F^x) \); let us compute the values \( s, t, d \in R \) such that

\[
\alpha_{H,H^x}(\text{lc}(f_{H^x}))s + \alpha_{H,s}(\text{lc}(g_i))t = \gcd(\alpha_{H,H^x}(\text{lc}(f_{H^x})), \alpha_{H,s}(\text{lc}(g_i))) = d
\]

and define \( f_H := s \tau_H^{-1} \star f_{H^x} + t \tau_H^{-1} \star g_s \) which satisfies \( M(f_H) = dT(H) = d\tau_H e_H \) so that

1. \( T(f_H) = T(H) = \tau_H e_H \),
2. \( \text{lc}(f_H) = \gcd(\alpha_{H,H^x}(\text{lc}(f_{H^x})), \alpha_{H,s}(\text{lc}(g_i))) = \gcd(\alpha_{H,s}(\text{lc}(g_i)) : i \in H) = d \),
3. it is sufficient to substitute \( f_{H^x} \) with its left Gröbner representation, to obtain the required Gröbner representation of \( f_H \). \( \square \)

**Proposition 54** (Möller). With the present notation and under the assumption that \( R \) is a principal ideal domain, the following conditions are equivalent:

1. \( F \) is a left Gröbner basis of \( M \);
2. a completion of \( F \) is a strong left Gröbner basis of \( M \).

**Proof.**

(1) \( \implies \) (2) Let \( f \in M \) and let \( f = \sum_{i=1}^u h_i \star g_i \) be a left Gröbner representation; denoting \( H := \{ j : T(h_j \star g_j) = T(f) = : \tau \epsilon \} \) we have \( \tau_H | \tau, e_H = \epsilon \). Thus, setting \( \nu_j := \frac{\tau}{\tau_H} \), \( \omega_j := \frac{\tau_H}{\tau} \) for each \( j \) and \( \lambda := \sum_{j \in H} \frac{\tau_H}{\tau} \) we have

\[
\text{lc}(f) = \sum_{j \in H} \text{lc}(h_j) \alpha_{\nu_j}(\text{lc}(g_j)) = \sum_{j \in H} \text{lc}(h_j) \alpha_{\lambda \omega_j}(\text{lc}(g_j)) \in \text{I}(\alpha_{\lambda \omega_j}(\text{lc}(g_j)) : j \in H) = \alpha_{\lambda}(I(\text{lc}(g_j)) : j \in H) = \alpha_{\lambda}(\text{I}(\epsilon_H))
\]

41
so that \( \alpha(f_{H}) = \alpha_{i}(c_{H}) \mid \text{lcm}(f) \) and \( \text{lcm}(f) = d\alpha(f_{H}) \) with \( d \in R \). In conclusion we have \( M(f) = d \lambda \ast M(f_{H}) \).

(2) \( \implies \) (1) Let \( f \in M \) and let \( f = \textstyle \sum_{K \subseteq \mathcal{S}(F)} c_{K}t_{K}f_{K} \) be a strong left Gröbner representation of it in terms of a completion of \( F \); it is sufficient to substitute each \( f_{K} \) with a left Gröbner representation of it in terms of \( F \) to obtain the required representation.

\( \square \)

**Example 55.** In Example 38, we finally have (see Remark 39)

\[ f_{[1,2]} = f_{[1,3]} = f_{[1,2,3]} = s_{L}(s_{i}) = s_{L}(s_{j}) = (y - 1)Y_{1}Y_{2}Y_{3}^{2}. \]

\( \square \)

**Example 56.** In Example 44 the strong Gröbner basis (see Example 48) is

\[ \{ f_{1}, f_{2}, f_{3}, f_{4}, f_{[1,2,3,4]} \} \]

since

\[
gcd(\alpha_{[1,2],[1]}(\text{lcm}(f_{1})), \alpha_{[1,2],[2]}(\text{lcm}(f_{2}))) = gcd(\alpha_{1}(x), \alpha_{2}(x)) = gcd(20x, 36x) = 4x
\]

\[
gcd(\alpha_{[1,2,3],[1,2]}(\text{lcm}(f_{[1,2]})), \alpha_{[1,2,3],[3]}(\text{lcm}(f_{3}))) = gcd(\alpha_{1}(4x), \alpha_{1}(x)) = gcd(4x, 15x) = x.
\]

Similarly, \( f_{[2,4]} = f_{4} \) follows trivially from

\[
gcd(\alpha_{[2,4],[2]}(\text{lcm}(f_{2})), \alpha_{[2,4],[4]}(\text{lcm}(f_{4}))) = gcd(\alpha_{2}(x^2), \alpha_{1}(x)) = gcd(36x^2, x) = x.
\]

\( \square \)

### 6.4 Useless S-pairs and Gebauer–Möller sets

Let us still assume that the Zacharias domain \( R \) is a principal ideal domain and we will use freely notations as \( M(i), M(i, j), M(i, j, k), 1 \leq i, j, k \leq u \) instead of \( M(\langle i \rangle), M(\langle i, j \rangle), M(\langle i, j, k \rangle) \), introduced in 6.1; we can then easily apply to the present setting the reformulation and improvement by Gebauer–Möller [19] of Buchberger Criteria [9]. However, we must be aware that, in this context, there is no chance of reformulating Buchberger’s First Criterion.

**Remark 57.** In fact, for \( F \subset \mathcal{P} = R[Y_{1}, \ldots, Y_{u}] \) and \( \mathcal{I}(F) \) an ideal of \( \mathcal{P} \), we should at least require that

\[
M(i) \ast M(j) = M(j) \ast M(i) = M(i, j)
\]

*Id est* not only \( \text{lcm}(\tau_{i}, \tau_{j}) = \tau_{i} \circ \tau_{j} = \tau_{j} \circ \tau_{i} \) which is trivially true but also

\[
\text{lcm}(\alpha_{\tau_{i}}(c_{i}), \alpha_{\tau_{j}}(c_{j})) = c_{i} \alpha_{\tau_{i}}(c_{i}) = c_{j} \alpha_{\tau_{j}}(c_{j}).
\]

This essentially requires \( c_{i} \mid \alpha_{\tau_{i}}(c_{i}) \) and \( c_{j} \mid \alpha_{\tau_{j}}(c_{j}) \) whence \( \alpha_{\tau_{j}} = \text{Id} \); this suggests that Buchberger’s First Criterion hardly can be applied.

Note that the proof which considers the trivial syzygies \( g_{i}g_{j} - g_{j}g_{i} = 0 \) holds only in the classical polynomial ring case.

\( \square \)
Definition 58. A useful S-pair set for $F$ is any subset
\[ 6\mathfrak M \subseteq S(u) = \{ (i, j) : 1 \leq i < j \leq u, e_i = e_j \} \]
such that $\{ b(i, j) : (i, j) \in 6\mathfrak M \}$ is a Gebauer–Möller set for $F$.

Corollary 59. With the present notation, under the assumption that $R$ is a principal ideal domain, $F$ is a left Gröbner basis of the left module $M$ iff $6\mathfrak M$ a useful S-pair set for $F$, each $S$-polynomial $B(i, j), (i, j) \in 6\mathfrak M$, has a left Gröbner representation in terms of $F$.

Proof. By definition $\{ b(i, j) : (i, j) \in 6\mathfrak M \}$ is a Gebauer–Möller set for $F$ so that, by Theorem 36, $F$ is a Gröbner basis of $M$ iff each $S$-polynomial $B(i, j), (i, j) \in 6\mathfrak M$, has a Gröbner representation in terms of $F$. \qed

If we moreover define,
- for each $i, j : 1 \leq i, j \leq u, e_i = e_j$,
  \[ c(i, j) = \text{lcm}(\alpha_{(i,j)}, \alpha_{(i,j)}) \]
  \[ \tau(i, j) = \text{lcm}(\tau_i, \tau_j) \]
  \[ \mu(i, j) = c(i, j)\tau(i, j) \]
- and for each $i, j, k : 1 \leq i, j, k \leq u, e_i = e_j = e_k$,
  \[ c(i, j, k) = \text{lcm}(\alpha_{(i,j,k)}, \alpha_{(i,j,k)}(c(i, j)), \alpha_{(i,j,k)}(c(i, k)), \alpha_{(i,j,k)}(c(j, k))) \]
  \[ \tau(i, j, k) = \text{lcm}(\tau_i, \tau_j, \tau_k) \]
  \[ \mu(i, j, k) = c(i, j, k)\tau(i, j, k) \]
and we impose on the set
\[ S(u) := \{ (i, j) : 1 \leq i < j \leq u, e_i = e_j \} \]
the ordering $\prec$ defined by
\[ \{ i_1, j_1 \} < \{ i_2, j_2 \} \iff \begin{cases} \tau(i_1, j_1) < \tau(i_2, j_2) & \text{or} \\ \tau(i_1, j_1) = \tau(i_2, j_2), j_1 < j_2 & \text{or} \\ \tau(i_1, j_1) = \tau(i_2, j_2), j_1 = j_2, i_1 < i_2, \end{cases} \]
we obtain

Definition 60. An S-element $b(i, j), 1 \leq i < j \leq u, e_i = e_j$, and the related S-pair $\{ i, j \}$ are called redundant if either
(a). exists $k > j, e_k = e_i = e_j$ such that
\[ \mu(i, j, k) = \mu(i, j); \mu(i, k) \neq \mu(i, j) \neq \mu(j, k) \]
(b). or exists $k < j, e_i = e_j = \mu(k, j) \mid \mu(i, j) \neq \mu(k, j)$ \qed
Lemma 61 (Møller). The following holds

1. for each \(i, j, k : 1 \leq i, j, k \leq u, \mathbf{e}_i = \mathbf{e}_j = \mathbf{e}_k\), it holds

\[
\frac{\mu(i, j, k)}{\mu(i, k)} b(i, k) - \frac{\mu(i, j, k)}{\mu(i, j)} b(i, j) + \frac{\mu(i, j, k)}{\mu(k, j)} b(k, j) = 0.
\]

2. \( \mathcal{R} := \{b(i, j), 1 \leq i < j \leq u, \mathbf{e}_i = \mathbf{e}_j\) and not redundant\} is a useful S-element set.

3. Let \(G := \{g_1, \ldots, g_s\}, s \leq u\), and let

\(\frak{G}_n \subset \{[i, j], 1 \leq i < j \leq s, \mathbf{e}_i = \mathbf{e}_j\}\)

be a useful S-pair set for \(G_* = \{g_1, \ldots, g_{s-1}\}\).

Let \(\overline{M} := \{\mu(j, s) : 1 \leq j < s, \mathbf{e}_i = \mathbf{e}_j\}\) and let \(\overline{M}' \subset \overline{M}\) be the set of the elements

\(\mu := \mu(j, s) \in \overline{M}\) such that there exists \(\mu(j', s) \in \overline{M} : \mu(j', s) | \mu(j, s) \neq \mu(j', s)\).

For each \(\mu = \mathbf{M}(j, s) \in \overline{M} \setminus \overline{M}'\) let \(i_\mu, 1 \leq i_\mu < s\), be such that \(\mu = \mathbf{M}(i_\mu, s)\). Then

\(\frak{G}_n := \frak{G}_n \cup \{[i_\mu, s] : \mu \in \overline{M} \setminus \overline{M}'\}\)

is a useful S-pair set for \(G\).

Proof. 1. (cf. [31, Lemma 25.1.4]) One has

\[
\begin{align*}
\frac{\mu(i, j, k)}{\mu(i, k)} b(i, k) - \frac{\mu(i, j, k)}{\mu(i, j)} b(i, j) + \frac{\mu(i, j, k)}{\mu(k, j)} b(k, j) \\
= \frac{\mu(i, j, k)}{\mu(i, k)} \left(\mu(i, k) \epsilon_k - \frac{\mu(i, k)}{\mu(i)} \epsilon_i\right) \\
- \frac{\mu(i, j, k)}{\mu(i, j)} \left(\mu(i, j) \epsilon_j - \frac{\mu(i, j)}{\mu(i)} \epsilon_i\right) \\
+ \frac{\mu(i, j, k)}{\mu(k, j)} \left(\mu(k, j) \epsilon_j - \frac{\mu(k, j)}{\mu(k)} \epsilon_i\right) \\
= \left(\frac{\mu(i, j, k)}{\mu(k)} \epsilon_k - \frac{\mu(i, j, k)}{\mu(i)} \epsilon_i\right) \\
- \left(\frac{\mu(i, j, k)}{\mu(j)} \epsilon_j - \frac{\mu(i, j, k)}{\mu(i)} \epsilon_i\right) \\
+ \left(\frac{\mu(i, j, k)}{\mu(j)} \epsilon_j - \frac{\mu(i, j, k)}{\mu(k)} \epsilon_i\right) \\
= 0
\end{align*}
\]

2. (cf. [31, Lemma 25.1.8]) In order to prove the claim by induction, it is sufficient to show that, for each redundant \([i, j], 1 \leq i < j \leq u, \mathbf{e}_i = \mathbf{e}_j = : \epsilon\), there are

- \([i_1, j_1], \ldots, [i_p, j_p], \ldots, [i_r, j_r], 1 \leq i_p < j_p \leq u, \mathbf{e}_{i_p} = \mathbf{e}_{j_p} = \epsilon\),
- elements \(t_1, \ldots, t_r \in \mathcal{T}\),

44
and coefficients $c_1, \ldots, c_r \in R \setminus \{0\}$ such that

- $b(i, j) = \sum p \ c_p q_p \ast b(i_p, j_p)$;
- $\tau(i, j) = t_p \circ \tau(i_p, j_p)$, for each $p$;
- $\{i_p, j_p\} < \{i, j\}$.

In order to show this, we only need to consider the representation

$$b(i, j) = \frac{\mu(i, j, k)}{\mu(i, k)} \ast b(i, k) + \frac{\mu(i, j, k)}{\mu(k, j)} \ast b(k, j)$$

and to prove that

$$\{i, k\} \prec \{i, j\} \succ \{k, j\};$$

this happens (according to the two cases of the definition) because

(a) $\tau(i, k) \setminus \tau(i, j, k) = \tau(i, j) \neq \tau(i, k)$ implies $\{i, k\} \prec \{i, j\}$ and the same argument proves $\{j, k\} < \{i, j\}$;

(b) the same argument as that above proves $\{j, k\} < \{i, j\}$, while $\{i, k\} < \{i, j\}$ because $\tau(i, k) \lessdot \tau(i, j)$ and $k < j$.

3. (cf. [31, Lemma 25.1.9]) Let $i < s$, $e_i = e_s := \epsilon, \mu := \mu(i, s)$. Then:

- if there exists $i' < s$ such that $\mu(i', s) = \mu(i, s) \neq \mu'$, then since $i' < s$, $\{i, s\}$ is redundant;
- if $i = i'$ then $\{i, s\} \in \emptyset$;
- if $i \neq i'$ then $b(i, s) = \frac{\mu(i, s)}{\mu(i', s)} b(i, i') - b(i, s)$.

$\square$

**Corollary 62.** With the present notation, under the assumption that $R$ is a principal ideal domain, $F$ is a left Gröbner basis of $\mathcal{M}$ iff each $S$-polynomial $B(i, j)$, with $b(i, j) \in R$, has a left Gröbner representation in terms of $F$. $\square$

**Example 63.** In connection with Lemma 61 we have

| $(i, j, k)$ | $c(i, j, k)$ | $\mu(i, j, k)$ | $b(i, j, k)$ |
|-------------|-------------|----------------|--------------|
| $(1, 2, 3)$ | $6^3 \cdot 5x^5$ | $Y_1^2 Y_2^2 Y_3^2$ | $b(1, 2) - 2^2 3^2 x b(1, 3) + b(2, 3) = 0$. |
| $(1, 2, 4)$ | $6^3 \cdot 5x^5$ | $Y_1^2 Y_2^2 Y_3^2$ | $b(1, 2) - 2^2 3^2 x b(1, 4) + 5 Y_2 \ast b(2, 4) = 0$. |
| $(1, 3, 4)$ | $60x$ | $Y_1^2 Y_2^2 Y_3^2$ | $b(1, 3) - b(1, 4) + 2 b(3, 4) = 0$. |
| $(2, 3, 4)$ | $6^3 \cdot 5x^5$ | $Y_1^2 Y_2^2 Y_3^2$ | $b(2, 3) - 5 Y_2 \ast b(2, 4) + 6^3 b(3, 4) = 0$. |

Note that we obviously [20, 34] have also

$$b(1, 2, 3) - b(1, 2, 4) + 2^2 3^2 x b(1, 3, 4) - b(2, 3, 4).$$

Thus the redundant elements are $b(2, 3)$ via 1 or 4, $b(1, 2)$ via 4 and $b(1, 4)$ via 3.

But, as it is well-known, it is more efficient (at least for storing considerations) the algorithm sketched in Lemma 61.3 which
for $s = 2$ stores $(1, 2)$,

for $s = 3$ stores $(1, 3)$,

for $s = 4$ removes $(1, 2)$ and stores $(2, 4)$ and $(3, 4)$.

Thus the Gebauer-Möller set is still 
\{b(1, 3), b(2, 4), b(3, 4)\}

while
\begin{align*}
b(1, 4) &= b(1, 3) + 2b(3, 4), \\
b(2, 3) &= 5Y_2 * b(2, 4) + 6^3 b(3, 4), \\
b(1, 2) &= 2^2 3^3 x b(1, 4) - 5Y_2 * b(2, 4).
\end{align*}

7 Weispfenning Completions for Bilateral Gröbner basis for Multivariate Ore Extensions of Zacharias Domains

7.1 Kandri-Rody–Weispfenning completion

Let $R$ be a not necessarily commutative domain and $\mathcal{R}$ a multivariate Ore extension.

The most efficient technique for producing bilateral Gröbner bases $G := \mathbb{I}_2(\mathcal{F})$ in a noetherian Ore extension is Kandri-Rody–Weispfenning completion [22]. Iteratively:

- Repeat
  - Compute a left-Gröbner basis $G$ of the ideal $\mathbb{I}_L(\mathcal{F})$;
  - for each $g \in G$, $1 \leq i \leq n$, compute the normal form $NF(g \star Y_i, \mathbb{I}_L(\mathcal{F}))$ of $g \star Y_i$, w.r.t. $G$;
  - set $H := (NF(g \star Y_i, \mathbb{I}_L(\mathcal{F})), g \in G, 1 \leq i \leq n)$, $F := F \cup H$
  - until $H = \{0\}$.

The rationale of the algorithm is

Lemma 64 (Kandri-Rody–Weispfenning). For $G \subset \mathcal{R}$ the following conditions are equivalent:

1. $\mathbb{I}_L(G) = \mathbb{I}_2(G)$;

2. for each $\tau \in \mathcal{T}$ and each $g \in G$, $g \star \tau \in \mathbb{I}_L(G)$;

3. for each $i, 1 \leq i \leq n$, and each $g \in G$, $g \star Y_i \in \mathbb{I}_L(G)$. 

46
Proof.

(1) $\implies$ (2) $\iff$ (3) is trivial.

(2) $\implies$ (1) $\B_2(G) := \{\lambda \star g \star \rho : \lambda, \rho \in T, g \in G\}$ is an $R$-linear basis of $I_2(G)$ and satisfies

$\B_2(G) = \{\lambda \star (g \star \rho) : \lambda, \rho \in T, g \in G\} \subseteq \{\lambda \star h : \lambda \in T, h \in I_2(G)\} \subseteq I_2(G)$.

$\square$

7.2 Weispfenning: Restricted Representation and Completion

We remark that a generic ring $R$ can be effectively given as a quotient of a free monoid ring $R := \mathbb{Z}(\mathfrak{v})$ over $\mathbb{Z}$ and the monoid ($\mathfrak{v}$) of all words over the alphabet $\mathfrak{v}$ modulo a bilateral ideal $I$, so, in this section, $R = R/I$.

We must restrict ourselves to the case in which $<\in T$ is a sequential term-ordering, id est for each $\tau \in T$, the set $\{\omega \in T : \omega < \tau\}$ is finite.

Lemma 65. [53] Let

$F := \{g_1, \ldots, g_u\} \subset \mathbb{R}^n$, $g_i = M(g_i) - p_i =: c_i \tau_i \varrho_i - p_i$;

set $\Omega := \max_{n \in [1, u]} \{\lambda(g_i) : 1 \leq i \leq u\}$.

Let $M$ be the bilateral module $M := I_2(F)$ and $I^\text{W}(F)$ the restricted module

$I^\text{W}(F) := \text{Span}_R(af \star \rho : a \in R \setminus \{0\}, \rho \in T, f \in F)$.

If every $f \star \alpha_\varphi(v), f \in F, v \in \mathfrak{v}, v \in T, v < \Omega$, has a restricted representation in terms of $F$ w.r.t. a sequential term-ordering $<$, then every $f \star r, f \in F, r \in R$, has a restricted representation in terms of $F$ w.r.t. $<$. 

Proof. We can wlog assume $r = \prod_{i=1}^{n} v_i, v_i \in \mathfrak{v}$ and prove the claim by induction on $v \in \mathbb{N}$.

Thus we have a restricted representation in terms of $F$

$f \star \left( \prod_{i=1}^{n} v_i \right) = \sum_{j} d_j g_{i,j} \star \rho_j, \tau_{i,j} \circ \rho_j \leq T(f)$,

whence we obtain

$f \star \prod_{i=1}^{n} v_i = f \star \prod_{i=1}^{n} v_i \star v_r = \sum_{j} d_j g_{i,j} \star \rho_j \star v_r = \sum_{j} d_j g_{i,j} \star \alpha_{\rho_j}(v_r)\rho_j$

and since $\rho_j < T(f) \leq \Omega$ each element $g_{i,j} \star \alpha_{\rho_j}(v_r)$ can be substituted with its restricted representation whose existence is granted by assumption. $\square$

Lemma 66. [53] Under the same assumption, if, for each $g_j \in F$, both $Y_i \star g_j, 1 \leq i \leq n$, and each $g_j \star \alpha_\varphi(v), v \in \mathfrak{v}, v \in T, v < \Omega$, have a restricted representation in terms of $F$ w.r.t. $<$, then $I^\text{W}(F) = M$. 

47
Corollary 67. Let above, also each $g_i$ allows to recover Buchberger First Criterion.

By assumption $f = \sum_j d_j g_i \star \rho_j, d_j \in R \setminus \{0\}, \rho_j \in T, 1 \leq i_j \leq u$, so that

$$Y_i \star f = \sum_j \alpha_i(d_j) \star (Y_i \star g_i) \star \rho_j$$

and each $f \star v = \sum_j d_j g_i \star (\alpha_p(v)) \star \rho_j$;

by assumption each $Y_i \star g_i$ has a restricted representation in terms of $F$; for the Lemma above, also each $g_i \star \alpha_p(v)$ has a restricted representation in terms of $F$.

\[ \Box \]

Corollary 67. [53] Let

$$F := \{g_1, \ldots, g_n\} \subset R^m, g_i = M(g_i) - p_i = c_i, e_i - p_i.$$ 

Let $M$ be the bilateral module $M := \mathcal{I}_2(F)$ and $I_w(F)$ the restricted module

$$I_w(F) := \text{Span}_R(af \star \rho : a \in R \setminus \{0\}, \rho \in T, f \in F).$$

$F$ is the bilateral Gröbner basis of $M$ iff

1. denoting $\mathfrak{G}(F)$ any restricted Gebauer–Möller set for $F$, each $\sigma \in \mathfrak{G}(F)$ has a restricted quasi-Gröbner representation in terms of $F$;

2. for each $g_j \in F$, both $Y_i \star g_j, 1 \leq i \leq n$ and each $g_j \star \alpha_p(v), v \in T, \upsilon < \Omega$, have a restricted representation in terms of $F$ w.r.t. $\prec$.

7.3 Gebauer-Möller sets for Restricted Gröbner bases

In this section we assume, as in section 6.4, that the Zacharias domain $R$ is a principal ideal domain; $R$ is intended to be a multivariate Ore extension.

It is clear from Corollary 67 that the computation of a Gröbner basis can be obtained via Weispfenning’s completion, provided that we are able to produce restricted Gebauer-Möller sets; to do so, we need only to properly reformulate the results of Section 6.4.

We begin by remarking [12] that for each monomial $ct \in M(R)$ the function $g \mapsto cg \star \tau$ distributes, thus we can define a multiplication $\odot : R \times R \to R$ by setting

$$c_i \tau_i \circ c_j \tau_j := c_i c_j \tau_j \tau_i = c_j c_i \tau_i \tau_j =: c_j \tau_j \circ c_i \tau_i$$

which of course is commutative and thus, granting the trivial syzygy

$$g_i \circ g_j = g_j \circ g_i$$

allows to recover Buchberger First Criterion.

As a consequence, we can reformulate the notion of restricted Gröbner representation:

- we say that $f \in R^m \setminus \{0\}$ has a restricted Gröbner representation in terms of $G$ if it can be written as $f = \sum_{i=1}^u l_i \circ g_i$, with $l_i \in R, g_i \in G$ and $T(l_i) \circ T(g_i) \leq T(f)$ for each $i$. 

48
Let us denote, for each $i, j, 1 \leq i < j \leq u$, $e_i = e_j$,

\[ b_w(i, j) := \frac{\lcm(c_i, c_j)}{c_j} e_j \frac{\lcm(\tau_i, \tau_j)}{\tau_j} - \frac{\lcm(c_i, c_j)}{c_i} e_i \frac{\lcm(\tau_i, \tau_j)}{\tau_i} \]

\[ B_w(i, j) := \frac{\lcm(c_i, c_j)}{c_j} \frac{g_j}{\tau_j} - \frac{\lcm(c_i, c_j)}{c_i} \frac{g_i}{\tau_i} \]

and let us explicitly assume that

\[ - \text{ for each } g_j \in F, \text{ both } Y_i \star g_j, 1 \leq i \leq n, \text{ and each } g_j \star \alpha_t(v), v \in \overline{v}, v \in T, \nu \leq \Omega, \]

have a restricted representation in terms of $F$ w.r.t. $\prec$.

**Lemma 68** (Buchberger’s First Criterion). If $m = 1$, id est $F \subset \mathbb{R}$ and $\mathbb{I}_w(F)$ is an ideal of $\mathbb{R}$, then

\[ M(i) \circ M(j) = M(i, j) \iff \lcm(\tau_i, \tau_j) = \tau_i \tau_j \text{ and } \lcm(c_i, c_j) = c_i c_j \]

\[ \Rightarrow \text{NF}_w(B_w(i, j), F) = 0. \]

**Proof.** We will prove that $B_w(i, j)$ has a restricted Gröbner representation in terms of $F$; thus the result will follow by the equivalence (4) $\iff$ (8) in Proposition 19.

Remark that

\[ p_i := g_i - M(i) = \sum t_{il} c_i \]

\[ p_j := g_j - M(j) = \sum t_{jk} c_j \]

satisfy $T(p_i) < T(g_i), T(p_j) < T(g_j)$.

Then it holds:

\[ 0 = g_i \circ g_j - g_i \circ g_j = M(i) \circ g_j + p_i \circ g_j - M(j) \circ g_i - p_j \circ g_i, \]

and

\[ B_w(i, j) := \frac{M(i, j)}{M(i)} \circ g_j - \frac{M(i, j)}{M(i)} \circ g_i = M(i) \circ g_j - M(j) \circ g_i = p_j \circ g_i - p_i \circ g_j. \]

There are then two possibilities: either

\[ - M(p_j) \circ M(g_i) \neq M(p_i) \circ M(g_j) \text{ in which case} \]

\[ T(B_w(i, j)) = \max(T(p_j) \circ T(g_i), T(p_i) \circ T(g_j)) \]

and

\[ B_w(i, j) = p_j \circ g_i - p_i \circ g_j = \sum c_{jk} g_i \star t_{jk} - \sum c_{ik} g_j \star t_{il} \]

is a restricted Gröbner representation;
Proof. Let \( \mathbf{S} \) be a useful S-pair set for \( F \), so that \( b(i, j) \in \{ i, j \} \in \mathcal{C}_a \) is a Gebauer–Möller set for \( F \).

A useful S-pair set for \( F \) is any subset

\[
\mathcal{C}_a := \left\{ \{ i, j \} : M(i) \circ M(j) = M(i, j) \right\}
\]

of \( \mathcal{S}(u) \), such that \( \{ b(i, j) : \{ i, j \} \in \mathcal{C}_a \} \) is a Gebauer–Möller set for \( F \).

Corollary 70. With the present notation, under the assumption that \( R \) is a principal ideal domain, \( F \) is a Gröbner basis of \( \mathbb{M} \) if and only if each \( S \)-polynomial \( B_w(i, j) \{ i, j \} \in \mathcal{C}_a \), has a Gröbner representation in terms of \( F \).

Proof. By definition \( \mathcal{B}_w(i, j) \{ i, j \} \in \mathcal{C}_a \) is a Gebauer–Möller set for \( F \) so that, by Theorem 36, \( F \) is a Gröbner basis of \( \mathbb{M} \) if and only if each \( S \)-polynomial \( B_w(i, j) \{ i, j \} \in \mathcal{C}_a \) has a Gröbner representation in terms of \( F \).

The claim is a direct consequence of Buchberger’s First Criterion which states that for each \( \{ i, j \} \in \mathcal{C}_a \), \( B_w(i, j) \) has a weak Gröbner representation in terms of \( F \).

Definition 71. An \( S \)-element \( b(i, j) \), \( 1 \leq i < j \leq u \), \( e_k = e_{k,j} \), and the related \( S \)-pair \( \{ i, j \} \) are called redundant if either

(a) exists \( k > j \), \( e_k = e_{i,j} \) such that

\[
M(i, j, k) = M(i, j); \ M(i, k) \neq M(i, j) \neq M(j, k).
\]

(b) or exists \( k < j \), \( e_k = e_{i,j} \) such that

\[
M(i, j, k) = M(i, j); \ M(i, k) \neq M(i, j) \neq M(j, k).
\]

Lemma 72 (Möller). The following holds

1. for each \( i, j, k : 1 \leq i, j, k \leq u, e_k = e_{i,j} = e_{u,i} \), it holds

\[
\frac{c(i, j, k)}{c(i, k)} b(i, k) \cdot \frac{\tau(i, j, k)}{\tau(i, k)} - c(i, j, k) \cdot \frac{\tau(i, j, k)}{\tau(i, j)} + c(i, j, k) \cdot b(i, j) \cdot \frac{\tau(i, j, k)}{\tau(i, j)} + \frac{c(i, j, k)}{c(j, k)} b(k, j) \cdot \frac{\tau(i, j, k)}{\tau(k, j)} = 0.
\]

2. \( \mathcal{R} := \{ b(i, j) : 1 \leq i < j \leq u, e_k = e_{i,j} \text{ and not redundant} \} \) is a useful S-element set.
3. Let \( G := \{g_1, \ldots, g_s\}, s \leq u, \) and let
\[
\mathcal{M}_s \subset \{(i, j), 1 \leq i < j \leq s, e_i = e_j\}
\]
be a useful S-pair set for \( G_\ast = \{g_1, \ldots, g_{s-1}\} \).

Let \( \overline{M} := \{M(j, s) : 1 \leq j < s, e_j = e_s\} \) and let \( \overline{M} \subset \overline{M} \) be the set of the elements \( \mu := M(j, s) \in \overline{M} \) such that either
- there exists \( M(j', s) \in \overline{M} : M(j', s) \neq M(j, s) \) or
- (in case \( M \) is an ideal) there exists \( i_\mu, 1 \leq i_\mu < s : \)
\[
M(i_\mu) \circ M(s) = M(i_\mu, s) = \mu.
\]

For each \( \mu := M(j, s) \in \overline{M} \setminus \overline{M} \) let \( i_\mu, 1 \leq i_\mu < s, \) be such that \( \mu = M(i_\mu, s) \). Then
\[
\mathcal{M}_s := \mathcal{M}_s \cup \{(i_\mu, s) : \mu \in \overline{M} \setminus \overline{M}\}
\]
is a useful S-pair set for \( G \).

**Proof.** The proof is an adaptation of the one given in Lemma 61. \( \square \)

**Corollary 73.** With the present notation, under the assumption that \( R \) is a principal ideal domain, \( F \) is a restricted Gröbner basis of \( M \) iff

1. each S-polynomial \( B_W(i, j), (i, j) \in \mathcal{R}, \) has a restricted Gröbner representation in terms of \( F; \)
2. for each \( g_j \in F, \) both \( Y_i \star g_j, 1 \leq i \leq n \) and each \( g_j \star \alpha_\nu(v), v \in \mathcal{T}, \nu \in \Omega, \)
   have a restricted representation in terms of \( F \) w.r.t. \( <. \)

\( \square \)

### 8 Structural Theorem for Multivariate Ore Extensions of Zacharias PIDs

**Theorem 74 (Structural Theorem).** Let \( R \) be a left Zacharias principal ideal domain, \( R := R[Y_1, \ldots, Y_n] \) a multivariate Ore extension of \( R, < \) a term-ordering, \( M \subset R^n \) a left module generated by a basis \( F := \{g_1, \ldots, g_u\} \subset M, M(g_i) = c_i T, e_i, C(F) \) a completion of \( F, \mathcal{R} := \{B(i, j), 1 \leq i < j \leq u, e_i = e_j \) and not redundant\).

Then the following conditions are equivalent:

1. \( F \) is a left Gröbner basis of \( M; \)
2. \( C(F) \) is a left strong Gröbner basis of \( M; \)
3. \( \mathcal{B}(F) := \{\lambda g : \lambda \in T, g \in F\} \) is a Gauss generating set [31, Definition 21.2.1];
4. \( f \in M \iff \) it has a left Gröbner representation in terms of \( F; \)
(4). \( f \in M \iff \text{it has a left strong Gröbner representation in terms of } C(F)\);
(5). for each \( f \in R^n \setminus \{0\} \) and any normal form \( h \) of \( f \) w.r.t. \( F \), we have
\[
  f \in M \iff h = 0;
\]
(5). for each \( f \in R^n \setminus \{0\} \) and any strong normal form \( h \) w.r.t. \( C(F) \), we have
\[
  f \in M \iff h = 0;
\]
(6). for each \( f \in R^n \setminus \{0\} \), \( f - \text{Can}(f, M) \) has a strong Gröbner representation in terms of \( C(F) \);
(7). each \( B(i, j) \in R \) has a weak Gröbner representation in terms of \( F \);
(8). for each element \( \sigma \) of a Gebauer–Möller set for \( F \), the S-polynomial \( S_L(\sigma) \) has a left quasi-Gröbner representation in terms of \( F \).

**Proof.**

(1) \iff (1s) is Proposition 54;
(1) \iff (2) is trivial;
(1) \iff (5) \iff (3) is Proposition 19;
(1s) \iff (4) \iff (5s) is Proposition 19;
(1) \implies (6) is the content of Section 6.3;
(6) \implies (4) because for each \( f \in M, \text{Can}(f, M) = 0 \);
(1) \iff (7) is Corollary 49;
(1) \iff (3) \iff (8) is Theorem 36.

\( \square \)

9 **Spear’s Theorem**

For Gröbner bases in a ring \( \mathcal{A} \) given as quotient
\[
\Pi : Q := \mathbb{Z}(Z_1, \ldots, Z_n) \twoheadrightarrow \mathcal{A} \cong \frac{Q}{I}, \quad \mathcal{I} := \ker(\Pi),
\]
of a free associative algebra, a general approach is to directly apply Spear’s Theorem [49] [31, Proposition 24.7.3] [29], which, though not a tool for computation, can be helpful in order to understand the structure of \( \mathcal{A} \).

For the present setting, denoting
- \( f_{ij} := Y_i Y_j - \alpha_j(Y_i) Y_j - \delta_j(Y_i), 1 \leq i < j \leq n \),
- \( C := \{ f_{ij} : 1 \leq i < j \leq n \} \),
I := I_2(C)
and for each \( m \in \mathbb{N} \),
- \( \{e_1, \ldots, e_m\} \) the canonical basis of \( \mathbb{R}^m \),
- \( C^{(m)} := \{f_{ij} := f_{ij}e_i : 1 \leq i < j \leq n, 1 \leq i \leq m\} \),
we have the presentation
\[
\mathbb{R} = \mathbb{Q}/I, \quad I := \ker(\Pi), \quad \Pi : \mathbb{Q} := R\langle Y_1, \ldots, Y_n \rangle \to \mathbb{R}
\]
and, for each free \( \mathbb{R} \)-module \( \mathbb{R}^m, m \in \mathbb{N} \), the projection \( \Pi \) extends to the canonical projections, still denoted \( \Pi \),
\[
\Pi : \mathbb{Q}^m \to \mathbb{R}^m, \quad \ker(\Pi) = I^m = I_2(C^{(m)}).
\]
Thus denoting
- \( F := \{g_1, \ldots, g_u\} \subset \mathbb{R}^m, g_i = \mathbf{M}(g_i) - p_i := c_iT_i e_i - p_i \),
- \( M \subset \mathbb{R}^m \) the module \( M := I_2(F) \),
- \( M' := \Pi^{-1}(M) = M + I^m \subset \mathbb{Q}^m \),
we can reformulate Spear’s result as

**Lemma 75.** [29, Lemma 12] Assume \( F \subset M' \) is a \( \text{Gröbner basis} \) of \( M' \) and denote
\[
\bar{F} := \{\text{Can}(g, I^m) : g \in F, T(g) \notin T(I^m) \} \subset \mathbb{R}[Y_1, \ldots, Y_n]^m
\]
where \( \text{Can}(g, I^m) \) denotes the canonical form of \( g \in \mathbb{Q}^m \) w.r.t. \( C^{(m)} \) so that in particular \( g = \Pi(g) \) for each \( g \in \bar{F} \).
Then \( \bar{F} \cup C^{(m)} \) is a \( \text{Gröbner basis} \) of \( M' \).

**Theorem 76** (Spear). [29, Theorem 13] With the present notation, the following holds:

1. if \( F \) is a reduced \( \text{Gröbner basis} \) of \( M' \), then
\[
\{g \in F : g = \Pi(g)\} = \{\Pi(g) : g \in F, T(g) \notin T(I^m)\} = F \cap \mathbb{R}[Y_1, \ldots, Y_n]^m
\]
is a reduced \( \text{Gröbner basis} \) of \( M' \);

2. if \( F \subset \mathbb{R}[Y_1, \ldots, Y_n]^m \), so that in particular \( \Pi(f) = f \) for each \( f \in F \), is the \( \text{Gröbner basis} \) of \( M \), then \( F \cup C^{(m)} \) is a \( \text{Gröbner basis} \) of \( M' \).

3. Assume each \( m' \in M' \) has a \( \text{Gröbner representation} \) in terms of \( F \subset M' \).
Set
\[
\bar{F} := \{\text{Can}(g, I^m) : g \in F, g \notin I^m \} \subset \mathbb{R}[Y_1, \ldots, Y_n]^m
\]
where \( \text{Can}(g, I^m) \in \mathbb{R}[Y_1, \ldots, Y_n]^m \) denotes the canonical form of \( g \in \mathbb{Q}^m \) w.r.t. \( C^{(m)} \) so that in particular \( g = \Pi(g) \) for each \( g \in \bar{F} \).
Then each \( m \in M \) has a \( \text{Gröbner representation} \) in terms of \( \bar{F} \).
4. if \( F \subseteq \mathbb{R}[Y_1, \ldots, Y_n]^m \), so that in particular \( \Pi(f) = f \) for each \( f \in F \), is such that each \( m \in M \) has a \( \text{Gröbner} \) representation in terms of \( F \), then each \( m' \in M' \) has a \( \text{Gröbner} \) representation in terms of \( F \cup C(m) \).

**Corollary 77.** [29, Corollary 14] With the present notation and considering

- the bilateral \( \mathbb{R} \)-module \((\mathbb{R} \otimes_{\mathbb{R}} \mathbb{R}^{op})^u \) with canonical basis \( \{e_1, \ldots, e_n\} \),
- the bilateral \( \mathbb{Q} \)-module \((\mathbb{Q} \otimes_{\mathbb{R}} \mathbb{Q}^{op})^{[F]+m|G]} \) with canonical basis
  \[
  \{e_1, \ldots, e_n\} \cup \{e_{ij} : 1 \leq i < j \leq n, 1 \leq \iota \leq m\},
  \]
- the projections \( \Xi_2 : (\mathbb{R} \otimes_{\mathbb{R}} \mathbb{R}^{op})^{[F]} \to \mathbb{R}^m : \Xi_2(e_i) = g_i, 1 \leq i \leq u, \) and
- \( \hat{\Xi}_2 : (\mathbb{Q} \otimes_{\mathbb{R}} \mathbb{Q}^{op})^{[F]+m|C]} \to \mathbb{Q}^m : \hat{\Xi}_2(e_i) = g_i, 1 \leq i \leq u, \hat{\Xi}_2(e_{ij}) = f_{ij}, 1 \leq i < j \leq n, 1 \leq \iota \leq m, \)
- the map
  \[
  \bar{\Pi} : (\mathbb{Q} \otimes_{\mathbb{R}} \mathbb{Q}^{op})^{[F]+m|C]} \to (\mathbb{R} \otimes_{\mathbb{R}} \mathbb{R}^{op})^{[F]}
  \]
  (where each \( \lambda, \rho \in \mathbb{R}[Y_1, \ldots, Y_n], a, b \in \mathbb{R} \setminus \{0\} \))
  
  \[
  \bar{\Pi}
  \left( \sum_i a_i \lambda_i e_i b_i \rho_i + \sum_{i,j} a_{ij} \lambda_{ij} e_{ij} b_{ij} \rho_{ij} \right) = \sum_i a_i \Pi(\lambda_i) e_i b_i \Pi(\rho_i),
  \]

if \( \Sigma \subseteq (\mathbb{Q} \otimes_{\mathbb{R}} \mathbb{Q}^{op})^{[F]+m|C]} \) is a bilateral standard basis of \( \ker(\Xi_2) \), then \( \Pi(\Sigma) \) is a bilateral standard basis of \( \ker(\hat{\Xi}_2) \).

### 10 Lazard Structural Theorem for Ore Extensions over a Principal Ideal Domain

Let \( \mathbb{D} \) be a commutative principal ideal domain, \( \mathbb{R} := \mathbb{D}[Y; \alpha, \delta] \) be an Ore extension and \( 1 \subseteq \mathbb{R} \) be a bilateral ideal.

Let \( F := \{f_0, f_1, \ldots, f_k\} \) be a reduced minimal strong bilateral \( \text{Gröbner} \) basis of \( 1 \) ordered so that

\[
\deg(f_0) \leq \deg(f_1) \leq \cdots \leq \deg(f_k)
\]

and let us denote, for each \( i, c_i := \text{lc}(f_i), r_i \in \mathbb{D} \setminus \{0\} \) and \( p_i \in \mathbb{R} \) the content\(^5\) and the primitive part of \( f_i \) so that \( f_i = r_i p_i \); denoting \( P := p_0 \) the primitive part of \( f_0 \) and \( G_k+1 := r_k \in \mathbb{D} \setminus \{0\} \) the content of \( f_k \) we have

**Theorem 78.** With the present notation, for each \( i, 0 < i \leq k, \) there is \( H_i \in \mathbb{R}, d(i) := \deg(H_i) \) and \( G_i \in \mathbb{D} \setminus \{0\} \) such that

---

\(^5\)Defined here as the greatest common divisor of the coefficients of \( f_i \) in the principal ideal domain \( \mathbb{D} \).
\[ f_0 = G_1 \cdots G_{k+1}P, \]
\[ f_j = G_{j+1} \cdots G_{k+1}H_jP, \quad 1 \leq j \leq k, \]
and

1. \( 0 < d(1) < d(2) < \cdots < d(k); \)
2. \( G_i \in \mathbb{D}, \quad 1 \leq i \leq k, \) is such that \( c_{i-1} = G_ic_i \)
3. \( P = p_0 \) (the primitive part of \( f_0 \in \mathbb{R} \));
4. \( H_i \in \mathbb{R} \) is a monic polynomial of degree \( d(i) \), for each \( i \);
5. \( H_{i+1} \in (G_1, \ldots, G_i, G_{i+1}, H_1, \ldots, G_{j+1}, \ldots, G_{k+1}, H_{j+1}) \) for all \( i \);
6. \( r_i = G_{i+1} \cdots G_{k+1} \).

**Proof.** Let \( P \) and \( G_{k+1} \) be, resp., the greatest common right divisor of \( \{p_0, \ldots, p_k\} \) in \( \mathbb{R} \) and the greatest common divisor of \( \{r_0, \ldots, r_k\} \) in \( \mathbb{D} \); since a set \( \{g_0, \ldots, g_k\} \) is a minimal strong Gröbner basis if and only if the same is true for \( \{rg_0, \ldots, rg_k\} \), \( r \in \mathbb{D}, g \in \mathbb{R} \), we can left divide by \( G_{k+1} \) and right divide by \( P \) and assume wlog that \( P = G_{k+1} = 1 \) and that both the greatest common right divisor of \( \{p_0, \ldots, p_k\} \) and the greatest common divisor of \( \{r_0, \ldots, r_k\} \) are 1.

Setting \( d(i) := \text{deg}(f_i) \) and \( \nu(i) := d(i+1) - d(i) \) for each \( i \), by assumption we have \( d(i) \leq d(i+1) \).

If \( d(i) = d(i+1) \), let us define

\[ h := b_if_i + b_{i+1}f_{i+1} \in \mathbb{D} \]

where \( c, b_i, b_{i+1} \in \mathbb{D} \) are such that \( b_ic_i + b_{i+1}c_{i+1} = c \), \( c \) being the greatest common divisor of \( c_i \) and \( c_{i+1} \), so that \( cY^{d(i+1)} = M(h) \in M(l) \); this implies the existence of \( j \) such that \( M(f_j) | M(h) | M(f_{i+1}) \) contradicting minimality; thus \( d(i) < d(i+1) \) and this, in turn, implies (1) since \( d(i) = d(i) - \text{deg}(P) \).

Both \( f_iY^\nu(i) \) and \( f_{i+1} \) are in the ideal and have degree \( d(i+1) \).

Therefore, for \( c, b_i, b_{i+1} \in \mathbb{D} \), \( b_ic_i + b_{i+1}c_{i+1} = c \), \( c \) being the greatest common divisor of \( c_i \) and \( c_{i+1} \), \( h := b_if_iY^{d(i+1)} - d(i+1) + b_{i+1}f_{i+1} \in \mathbb{D} \), so that \( cY^{d(i+1)} = M(h) \in M(l) \) and \( M(f_j) | M(h) \) for some \( j \). If \( c_{i+1} \neq c \), necessarily \( \text{deg}(f_j) < \text{deg}(f_{i+1}) \) whence \( j < i \) and \( M(f_j) | M(h) | M(f_{i+1}) \) getting a contradiction. As a conclusion \( c_i = G_{i+1}c_{i+1} \), for some \( G_{i+1} \in \mathbb{D} \) and (2).

Since \( G_{i+1}f_{i+1} - f_iY^\nu(i) \) is a polynomial of degree less than \( d(i+1) \) which reduces to zero by the Gröbner basis, it follows that

\[ G_{i+1}f_{i+1} \in \mathbb{D}(f_0, \ldots, f_i) \text{ for each } i, 0 \leq i < k; \]

thus, inductively we obtain

\[ p_0 \mid_R f_j \text{ for each } j \leq i \implies p_0 \mid_R f_j \text{ for each } j \leq i + 1. \]
Also
\[ c_i \mid_L f_j \text{ for each } j \leq i \implies G_{i+1}c_{i+1} = c_i \mid_L G_{i+1}f_{i+1} \]
\[ \implies c_{i+1} \mid_L f_j \text{ for each } j \leq i + 1. \]

Therefore, the assumptions that the greatest common right divisor of \( \{p_0, \ldots, p_k\} \) and the greatest common divisor of \( \{r_0, \ldots, r_k\} \) are 1 imply that \( p_0 = c_k = 1 \) proving (3); thus in particular \( f_0 = c_0 \) so that \( c_0 \mid f_0 \) and this is sufficient to deduce, by the inductive argument, that each \( c_i \) left-divides \( f_i \) and therefore coincides with \( r_i \).

Inductively we obtain
\[ r_i \lc(P) = c_i = G_{i+1}c_{i+1} = G_{i+1}r_{i+1} \lc(P) = G_{i+1} \cdots G_{k+1} \lc(P) \]
thus proving (6); defining \( H_i \) the polynomial s.t. \( c_i H_i P = f_i \) for all \( i \) we have \( \lc(H_i) = 1 \) (proving (4)), \( d(i) + \deg(P) = \deg(f_i) \) and \( G_{i+1}f_{i+1} \in (f_0, \ldots, f_i) \) which proves (5) dividing out \( G_{i+1} \cdots G_{k+1} \).

\[ \square \]

A The PIR case

While an understandable tabú restrained us to violate Ore’s tabu requiring degree preservation of product, it is well-known that Zacharias–Möller results are naturally stated for polynomials over PIRs and the restriction to PIDs is unnatural; we therefore sketch here the few modifications to the theory which are required in order to adapt it to Ore extensions \( \mathcal{R} \) over a PIR \( R \).

The first delicate adaptation is required by formula (4); the natural solution is due to Gateva [16, 17, 18] who considered valuation over the semigroup with zero \( \mathcal{T} \cup \{o\} \) instead of \( \mathcal{T} \) setting
\[ \circ : \mathbb{N} \times \mathbb{N} \to \mathbb{N} \cup \{o\} : u \circ v = \begin{cases} \mathcal{T}(u \star v) & u \star v \neq 0 \\ o & u \star v = 0. \end{cases} \]

Her theory however applies only to domains.

Thus in order to extend Corollary 15 we need to reformulate it as

**Corollary 15.** If \( \prec \) is a term ordering on \( \mathcal{T} \) and \( \prec \) is an \( \sim\)-compatible term ordering on \( \mathcal{T}^{(m)} \), then, for each \( l, r \in \mathcal{R} \) and \( f \in \mathcal{R}^{(m)} \),

1. \( M(l \star f) = M(M(l) \star M(f)) \) provided \( \lc(l) \lc(f) \neq 0; \)
2. \( M(f \star r) = M(M(f) \star M(r)) \) provided \( \lc(f) \lc(r) \neq 0; \)
3. \( M(l \star f \star r) = M(M(l) \star M(f) \star M(r)) \) provided \( \lc(l) \lc(f) \lc(r) \neq 0. \)
4. \( T(l \star f) \leq T(l) \circ T(f) \) equality holding provided that \( \lc(l) \lc(f) \neq 0; \)
5. \( T(f \star r) \leq T(f) \circ T(r) \) equality holding provided that \( \lc(f) \lc(r) \neq 0; \)
6. \( T(l \star f \star r) \leq T(l) \circ T(f) \circ T(r) \) equality holding provided that \( \lc(l) \lc(f) \lc(r) \neq 0. \)
Corollary 49. Assuming that the Zacharias ring $R$ is principal and denoting, for each $i$, $j$, $1 \leq i < j \leq u$, $e_i = e_j$,

\[
(b(i, j) := \frac{\text{lcm}(a_{[i,j],j}(c_i), a_{[i,j],j}(c_j))}{\alpha_{[i,j],j}(c_j)} \frac{\text{lcm}(\tau_i, \tau_j)}{\tau_j} e_j - \frac{\text{lcm}(a_{[i,j],j}(c_i), a_{[i,j],j}(c_j))}{\alpha_{[i,j],j}(c_i)} \frac{\text{lcm}(\tau_i, \tau_j)}{\tau_i} e_i,
\]

\[B(i, j) := \frac{\text{lcm}(a_{[i,j],j}(c_i), a_{[i,j],j}(c_j))}{\alpha_{[i,j],j}(c_j)} \frac{\text{lcm}(\tau_i, \tau_j)}{\tau_j} g_j \]

\[a(i) := a_i e_i \]

\[A(i) := a_i \star g_i, \]

we have that

\[\{b(i, j) : 1 \leq i < j \leq u, e_i = e_j\} \cup \{a(i), i \leq u\}\]

is a left Gebauer–Möller set for $F$, so that $F$ is a left Gröbner basis of $M$ iff each $B(i, j)$, $1 \leq i < j \leq u, e_i = e_j$, and each $A(i), i \leq u$, have a left weak Gröbner representation in terms of $F$.

\[\square\]

Corollary 51. Assuming that the Zacharias ring $R$ is principal and that each $\alpha_i$ is an automorphism denoting, for each $i$, $j$, $1 \leq i < j \leq u$, $e_i = e_j$,

\[b(i, j) := e_i \alpha_{\tau_j}^{-1} \left( \frac{\text{lcm}(c_i, c_j)}{c_j} \right) \frac{\text{lcm}(\tau_i, \tau_j)}{\tau_j} - e_i \alpha_{\tau_i}^{-1} \left( \frac{\text{lcm}(c_i, c_j)}{c_i} \right) \frac{\text{lcm}(\tau_i, \tau_j)}{\tau_i}\]

\[B(i, j) := g_j \star \alpha_{\tau_i}^{-1} \left( \frac{\text{lcm}(c_i, c_j)}{c_j} \right) \frac{\text{lcm}(\tau_i, \tau_j)}{\tau_j} - g_i \star \alpha_{\tau_i}^{-1} \left( \frac{\text{lcm}(c_i, c_j)}{c_i} \right) \frac{\text{lcm}(\tau_i, \tau_j)}{\tau_i}\]

\[a(i) := e_i \alpha_{\tau_i}^{-1}(c_i)\]

\[A(i) := g_i \star \alpha_{\tau_i}^{-1}(c_i)\]

57
we have that
\[ \{ b(i, j) : 1 \leq i < j \leq u, e_i^j = e_j \} \cup \{ a(i), i \leq u \} \]

is a right Gebauer–Möller set for \( F \), so that \( F \) is a right Gröbner basis of \( \mathbb{M} \) iff each \( B(i, j), 1 \leq i < j \leq u, e_i^j = e_j \), and each \( A(i), i \leq u \), have a right weak Gröbner representation in terms of \( F \).

**Proposition 54** (Möller). With the present notation and under the assumption that \( R \) is a principal ideal ring, the following conditions are equivalent:

1. \( F \) is a left Gröbner basis of \( \mathbb{M} \);
2. a completion of \( F \) is a strong left Gröbner basis of \( \mathbb{M} \).

Buchberger’s First Criterion, for the PIR case, is stated as

If \( F \subseteq \mathbb{P} \) and \( \mathbb{I}(F) \) is an ideal of \( \mathbb{P} \), it holds

\[
\mathbb{M}(i)\mathbb{M}(j) = \mathbb{M}(i, j) \iff \text{lcm}(\tau_i, \tau_j) = \tau_i \tau_j, \text{lcm}(c_i, c_j) = c_i c_j \\
\implies \text{NF}(B(i, j), F) = 0.
\]

**Corollary 59.** With the present notation, under the assumption that \( R \) is a principal ideal ring, \( F \) is a left Gröbner basis of the left module \( \mathbb{M} \) iff each \( S \)-pair set for \( F \), denoting \( \mathcal{W} \) a useful \( S \)-pair set for \( F \), each \( S \)-polynomial \( B(i, j), \{i, j\} \in \mathcal{W} \), and each \( A(i), 1 \leq i \leq u \), have a left Gröbner representation in terms of \( F \).

**Corollary 62.** With the present notation, under the assumption that \( R \) is a principal ideal ring, \( F \) is a left Gröbner basis of \( \mathbb{M} \) iff each \( S \)-polynomial \( B(i, j), \{i, j\} \in \mathcal{W} \), and each \( A(i), 1 \leq i \leq u \), has a left Gröbner representation in terms of \( F \).

**Corollary 73.** With the present notation, under the assumption that \( R \) is a principal ideal ring, \( F \) is a restricted Gröbner basis of \( \mathbb{M} \) iff

1. each \( S \)-polynomial \( B_W(i, j), \{i, j\} \in \mathcal{W} \), and each \( A(i), 1 \leq i \leq u \), has a restricted Gröbner representation in terms of \( F \);

2. for each \( g_j \in F \), both \( Y_i \star g_j, 1 \leq i \leq n \) and each \( g_j \star \alpha(v), v \in \overline{v}, v \in \mathcal{T}, v < T(g_j) \), have a restricted representation in terms of \( F \) w.r.t. \( < \).

Finally we remark that a Lazard Structural Theorem for Ore Extensions over a Principal Ideal Domain can be easily obtained by adapting the result given by Norton–Säälägean [36, 37], [31, § 33.3] for polynomial rings.
