Abstract
The effects of silver nanoparticles (Ag-MMT) incorporated into an alginate-based coating applied to fresh-cut melon (Cucumis melo L.) were assessed on the product shelf life. Different concentrations of Ag-MMT nanoparticles were tested in coated melon that was packaged in an oriented polypropylene-based bag and stored at 5°C. Results showed that the active coating was effective from the microbiological and the sensory point of view, if compared to the uncoated fruit that rapidly lost the characteristics responsible for fruit acceptance. A significant shelf life prolongation was recorded from less more than 3 days of the control samples to 11 days of coated fruit, thus promoting further investigation on Ag-MMT coating as valid preservation strategy.

Keywords: Silver nanoparticles; Coating; Fresh-cut melon; Shelf life

Introduction
Nanotechnology is an emerging technology also in food science where the interest for manufacturing new materials at the nanoscale level is growing [1]. Among the different types of nanoparticles (NPs), silver ones (AgNPs) have proved to be very effective as these compounds generally exert high antimicrobial activity against both Gram-positive and Gram-negative bacteria, such as methicillin resistant S. aureus [2] and E. coli, P. aeruginosa and S. faecalis [3]. The research in food science has exploited the nanotechnology to also develop new packaging materials with improved antimicrobial properties. In this context, a new class of antimicrobial systems has been generated from inorganic phyllosilicate clays, such as montmorillonite (MMT), which constitute a support for AgNPs. According to Bouwmeester [4], nanotechnologies currently applied to food can be divided in different production phases, from processing where NPs may appear in suspension or emulsion, to preservation and packaging. As a fact, NPs can be engineered as food additives or supplements for functionalized foods, such as nano-delivery systems [5,6] build from peptide, carbohydrate or lipid monomers [7-9]. On the other hand, some examples have been also found as NPs applied for preservation aims. Costa et al. [10] reported a significant shelf life prolongation of fresh fruit salad obtained with a new packaging system incorporating Ag-MMT as active compounds. The same authors also reported a significant shelf life prolongation of fresh-cut carrots treated with Ag-MMT [11]. Incoronato et al. [12] applied AgNPs to Fiordilatte cheese, thus demonstrating a significant enhancement of the fresh dairy product quality stored in the active packaging. Fresh-cut fruit and vegetables are increasingly available on supermarket shelves. The operations to obtain fresh-cut produce (washing, peeling and cutting) generally promote a faster physiological deterioration, biochemical change and microbial degradation [13]. Melon (Cucumis melo) in particular, is one of the most consumed fresh-cut fruit due to its attractive color, good flavor, refreshing properties and its high content of vitamins, mineral salts and fibers. Unfortunately, the shelf life of this product is strongly affected by the high amount of water and sugars which constitute an ideal substrate for microbial proliferation, besides the almost neutral pH does not constitute a natural barrier against pathogens. Moreover, melons are grown on the ground, thus contact with any organic fertilizers and the surface uneven and porous allows microorganisms to adhere very well, then cross contamination of the pulp at the time of cutting can easily occur. These reasons make necessary to develop valid preservation techniques to prevent the deteriorative processes that occur during processing and storage (microbial spoilage, desiccation, discoloration or browning, textural changes and development of off-odor). Edible coatings may reduce fresh-cut fruit deterioration, being able to control the respiration rate and the water loss and also serving as carriers of active compounds [14-16]. Moreover, the use of coatings as carriers of silver represents a viable approach to avoid the direct contact of nanoparticles with food [12,17]. The aim of this work was to evaluate the influence of alginate coating loaded with silver-montmorillonite nanoparticles (Ag-MMT) on shelf life of fresh-cut melon. To assess the influence of the active coating on the fresh-cut produce, both microbial and sensory quality decay were assessed during a proper refrigerated storage period.

Materials and Methods

Fruit preparation
‘Protea’ Melons (Cucumis melo L.) were kindly provided by a local farm (Futuragri, Foggia, Italy) at a commercial stage of ripeness, transported within 2 h directly from the field to the laboratory under refrigerated conditions and stored in a ventilated room at 4°C prior to processing. For the samples preparation a protocol including proper washing steps was followed. The whole fruit was firstly washed with tap water to remove residuals, dipped for 5 min in chlorinated water (20 ml L⁻¹) and finally washed in a 50% water-ethanol solution for the same time. Afterward, the whole fruit was air-dried for 10 min at room temperature (23°C), peeled, cut longitudinally using a manual vegetable cutter into slices of about 25 mm thickness and the pulp was further cut in trapezoidal sections (12 g). The coating solutions were prepared by dissolving food-grade sodium alginate powder (2% w/v) (Farmalabor, Canosa, Italy) in distilled water while heating on a stirring hot plate for 10 min at 70°C until the mixture became clear. Silver-montmorillonite nanoparticles (Ag-MMT) were kindly provided by...
the National Research Council of Naples (IPCB) that prepared the nano composite systems as also reported in another work [18]. The Ag-MMT nanoparticles were in the range of 10–40 nm and were added to the coating solution in concentrations of 150, 250 and 500 ppm (w/v), by stirring the solution for 30 min. Melon pieces were first dipped into each active solution for 2 min, the excess solution was allowed to drip off before submerging each fruit piece in a calcium chloride solution (5% w/w) for 5 min to promote the alginate gel forming. All samples were dried at room temperature for 2 min. A proper amount of coated samples corresponding to 100 g was packaged in an oriented polypropylene-based bag of 40 µm thickness. The bags were 250 mm × 250 mm long, with an Oxygen Transmission Rate (OTR) of 1171.72 ± 9.58 cc/(m² day) at 23°C and 0% RH. The bags were hermetically sealed by means of a thermal sealer (Gandus sealers, Milan, Italy) under air conditions and then stored at 5°C for the entire observation period (19 days). As reference sample, uncoated fresh-cut melon was also packaged. In the current work a coating without any active compounds was not taken into account because preliminary tests on the same cultivar melon highlighted that the behaviors of coated and uncoated samples were very similar. For the sake of clarity, the investigated samples were labeled as follows: CTRL (uncoated fresh-cut melon), Coat-150 (fresh-cut melon coated with 150 mg of Ag-MMT), Coat-250 (fresh-cut melon coated with 250 mg of Ag-MMT) and Coat-500 (fresh-cut melon coated with 500 mg of Ag-MMT).

**Microbiological analyses and pH determination**

Viable cell loads of main spoilage microorganisms were monitored for the entire observation period. For microbiological analyses, about 10 g of sample was aseptically removed from each package, placed in a stomacher bag, diluted with 0.9% NaCl solution and homogenized with a stomacher LAB Blender 400 (Pbi International, Milan, Italy). Decimal dilutions were carried out using the same diluent. Mesophiles and psychrotrophs were determined on Plate Count Agar (PCA) with incubation at 30°C for 24–48 h and 7°C for 10 days, respectively. For coliforms, Violet Red Bile Agar (VRBA) was used and plates were incubated at 37°C for 18–24 h. Yeasts and moulds were determined on Sabouraud Dextrose Agar (SDA), supplemented with chloramphenicol (0.1 g L⁻¹) (C. Erba, Milan, Italy) with incubation at 25°C for 48 h and 5 days, respectively. deManRogosa Sharpe agar (MRS), added with 0.17 g/L cycloheximide (Sigma-Aldrich, Milan, Italy) incubated at 30°C for 2–4 days for lactic acid bacteria (LAB). All the media used were from Oxoid (Milan, Italy). The microbiological analyses were carried out twice on two different batches. The measurement of pH on the first homogenized dilution of the fresh-cut melon was performed twice on two different batches, by using a pH-meter (Crisson, Barcelona, Spain).

**Sensory analyses**

During storage, fruit samples were submitted to a panel of 7 trained evaluators in order to assess the sensory attributes. According to a similar procedure reported in the literature [19] a 9-point scale was used to define the intensity of odor, color, firmness and overall quality. This last parameter has to be considered as an average of the other sensory attribute (i.e., color, odor, and firmness) as evaluated by quality. This last parameter has to be considered as an average of the other sensory attribute (i.e., color, odor, and firmness) as evaluated by quality. This last parameter has to be considered as an average of the other sensory attribute (i.e., color, odor, and firmness) as evaluated by quality. This last parameter has to be considered as an average of the other sensory attribute (i.e., color, odor, and firmness) as evaluated by quality. This last parameter has to be considered as an average of the other sensory attribute (i.e., color, odor, and firmness) as evaluated by quality.

where SA(t) is the fresh-cut melon overall quality at time t, k is the kinetic constant, SA is the initial value of the melon overall quality, SA_{min} is the limit for fresh-cut produce acceptability, SAL is the sensory acceptability limit (i.e., the time at which SA(t) is equal to SA_{min}), and t is the storage time.

**Statistical analysis**

The values of the microbial cell loads and the SAL values relative to the sensory quality were compared by one-way ANOVA, respectively. A Duncan’s multiple range test, with the option of homogeneous groups (p<0.05), was used to determine significance among differences. Statistical 7.1 for Windows (StatSoft Inc., Tulsa, OK, USA) was used for this purpose.

**Results and Discussion**

**Microbial quality**

Table 1 reports the cell load of mesophilic and psychrotrophic bacteria at 0 and 8 days of sampling for all the investigated samples. A concentration of 5×10⁶ CFU/g of total mesophilic bacteria was selected as threshold for microbial acceptability, as imposed by the French Regulation [21]. As can be seen from the table, the initial cell load accounted for about 2 log CFU/g. A gradual increase in mesophilic population was found for the uncoated melon (CTRL), until reaching the microbial threshold within a few days of storage (5 days). Differently, a low cell load was detected in all the active coated samples where the microbial threshold was never reached. Anyway, a certain differences among the active coated samples were found. In fact, while fresh-cut melon coated with the two lowest concentrations of Ag-MMT (Coat-150 and Coat-250) reached a microbial concentration of about 6.89 and 5.57 log CFU/g, respectively, on the 8th day of storage, the Coat-500 sample presented a cell load of 6.64 log CFU/g on day 13th and reached the threshold on day 19th (7.79 log CFU/g). This result confirmed the correlation between efficacy and Ag-MMT nanoparticles concentration, as also demonstrated in other applications of silver nanoparticles to fresh fruit [11]. The antimicrobial activity can be related to the silver ions released. When the silver ions enter the bacterial cells by penetrating through the cell wall turn the DNA into a condensed form to react with the thiol group proteins and provoke the cell death [22]. Morones et al. [23] studied the effect of silver nanoparticles on E. Coli growth and demonstrated that at concentration less above 75 µg/ml there was no bacterial growth. As regard the psychotropic bacteria, a trend similar to that found for the mesophilic count was recorded (data not shown). For the other investigated microbial groups (yeast, moulds and coliforms) a very low proliferation (about 4 log CFU/g), by one or two log cycles below the uncoated sample (CTRL) was recorded throughout the storage in all the active coated fruits.

The pH values showed a constant trend during the entire observation period, accounting for about 6 in all the active coated samples and about 4.9 in the uncoated sample.

**Sensory quality**

Figure 1 shows the evolution during storage of the fresh-cut melon overall quality for all the investigated samples. SAL values were listed in Table 2. The solid horizontal line is the overall quality threshold (score=5). As can be inferred from Figure 1, in accordance to the microbiological results, the uncoated sample (CTRL) rapidly falls down below the threshold, due to the fast color changes caused by dehydration. In fact, color is a critical quality parameter of fresh-cut fruit since cutting operations may often lead to enzymatic browning.
In this work the influence of an alginate coating loaded with different concentration of Ag-MMT nanoparticles on shelf life of fresh-cut melon was studied. To this aim, microbiological and sensory attributes were observed during the storage. Results suggested that the sensory parameters played a major role in determining the product acceptability because the coating treatment with Ag-MMT controlled the microbial growth and the melon did not overlap the microbiological limit imposed for fresh-cut fruit and vegetables. The combined use of alginate coating and silver nanoparticles allows maintaining good melon quality, thus prolonging the shelf life to about 11 days, with respect to the uncoated samples (3 days).

**Conclusions**

In this work the influence of an alginate coating loaded with different concentration of Ag-MMT nanoparticles on shelf life of fresh-cut melon was studied. To this aim, microbiological and sensory attributes were observed during the storage. Results suggested that the sensory parameters played a major role in determining the product acceptability because the coating treatment with Ag-MMT controlled the microbial growth and the melon did not overlap the microbiological limit imposed for fresh-cut fruit and vegetables. The combined use of alginate coating and silver nanoparticles allows maintaining good melon quality, thus prolonging the shelf life to about 11 days, with respect to the uncoated samples (3 days).

**Acknowledgement**

The authors thank the National Research Council of Naples (Istituto dei Polimeri, Composite Biomateriali-IPCB, Ing. G.G. Buonocore) to kindly provide the silver nanoparticles.
