The Subfield Codes of Ovoid Codes

Cunsheng Ding, Ziling Heng

Abstract

Ovoids in PG(3, GF(q)) have been an interesting topic in coding theory, combinatorics, and finite geometry for a long time. So far only two families of ovoids are known. The first is the elliptic quadratics and the second is the Tits ovoids. It is known that an ovoid in PG(3, GF(q)) corresponds to a [q^2 + 1, 4, q^2 - q] code over GF(q), which is called an ovoid code. The objectives of this paper is to study the subfield codes of the two families of ovoid codes. The dimensions, minimum weights, and the weight distributions of the subfield codes of the elliptic quadric codes and Tits ovoid codes are settled. The parameters of the duals of these subfield codes are also studied. Some of the codes presented in this paper are optimal, and some are distance-optimal. The parameters of the subfield codes are new.

Elliptic quadric, linear code, weight distribution, ovoid

I. INTRODUCTION

Let q be a prime power. Let n, k, d be positive integers. An [n, k, d] code C over GF(q) is a k-dimensional subspace of GF(q)^n with minimum (Hamming) distance d. Let A_i denote the number of codewords with Hamming weight i in a code C of length n. The weight enumerator of C is defined by 1 + A_1z + A_2z^2 + · · · + A_nz^n, The sequence (A_1, A_2, · · · , A_n) is called the weight distribution of the code C. A code C is said to be a t-weight code if the number of nonzero A_i in the sequence (A_1, A_2, · · · , A_n) is equal to t. An [n, k, d] code over GF(q) is called distance-optimal if there is no [n, k, d + 1] code over GF(q), and dimension-optimal if there is no [n, k + 1, d] code over GF(q). A code is said to be optimal if it is both distance-optimal and dimension-optimal.

A cap in the projective space PG(3, GF(q)) is a set of points in PG(3, GF(q)) such that no three of them are collinear. Let q > 2. For any cap V in PG(3, GF(q)), we have |V| ≤ q^2 + 1 (see [4], [16] and [15] for details). In the projective space PG(3, GF(q)) with q > 2, an ovoid V is a set of q^2 + 1 points such that no three of them are collinear (i.e., on the same line). In other words, an ovoid is a (q^2 + 1)-cap (a cap with q^2 + 1 points) in PG(3, GF(q)), and thus a maximum cap.

A classical ovoid V can be defined as the following set of points:

\[
V = \{(0, 0, 1, 0)\} \cup \{(x, y, x^2 + xy + ay^2, 1) : x, y \in GF(q)\},
\]

where a \in GF(q) is such that the polynomial x^2 + x + a has no root in GF(q). Such ovoid is called an elliptic quadric, as the points come from a non-degenerate elliptic quadratic form.

For q = 2^{e+1} with e ≥ 1, there is an ovoid which is not an elliptic quadric, and is called the Tits ovoid [17]. It is defined by

\[
T = \{(0, 0, 1, 0)\} \cup \{(x, y, x^\sigma + xy + y^{\sigma+2}, 1) : x, y \in GF(q)\},
\]

where \sigma = 2^e+1.

For odd q, any ovoid is an elliptic quadric (see [1] and [13]). For even q, Tits ovoids are the only known ones which are not elliptic quadratics. In the case that q is even, the elliptic quadrics and the Tits ovoid are not equivalent [18]. For further information about ovoids, the reader is referred to [14].

Z. Heng is with the Department of Computer Science and Engineering, The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, China (email: zilingheng@163.com)
Let \( S \) be a subset of \( \text{PG}(3, \text{GF}(q)) \) with \( q^2 + 1 \) elements, where \( q > 2 \). Denote by
\[
S = \{s_1, s_2, \ldots, s_{q^2+1}\}
\]
where each \( s_i \) is a column vector in \( \text{GF}(q)^4 \). Let \( C_S \) be the linear code over \( \text{GF}(q) \) with generator matrix
\[
G_S = [s_1s_2 \cdots s_{q^2+1}].
\]

The optimality and distance optimality of these codes are the motivation of this paper.

Ovoid codes are distance-optimal. The parameters of the sub field codes presented in this paper are new.

It will be seen later, some of these codes are optimal. In particular, the duals of the subfield codes of the elliptic quadric codes and Tits ovoid codes are determined. As

The following result is known (see [2, p. 192] or [9]).

**Theorem 1.1:** The set \( S \) is an ovoid if and only if \( C_S \) has parameters \([q^2 + 1, 4, q^2 - q]\).

Due to Theorem 1.1, any \([q^2 + 1, 4, q^2 - q]\) code over \( \text{GF}(q) \) is called an ovoid code. Ovoid codes are optimal, as they meet the Griesmer bound. It is also known that any \([q^2 + 1, 4, q^2 - q]\) code over \( \text{GF}(q) \) must have the following weight enumerator [2, p. 192]:
\[
1 + (q^2 - q)(q^2 + 1)z^{q^2-q} + (q-1)(q^2+1)z^{q^2}.
\]

It then follows that a linear code over \( \text{GF}(q) \) has parameters \([q^2 + 1, 4, q^2 - q]\) if and only if its dual has parameters \([q^2 + 1, q^2 - 3, 4]\). Ovoid codes and their duals are interesting due to the following:

- Ovoid codes meet the Griesmer bound and are thus optimal.
- The duals of ovoid codes are almost-MDS.
- Ovoid codes and their duals can be employed to construct 3-designs and inversive planes [9].
- Ovoid codes are also the maximum minimum distance (MMD) codes [10].

Let \( q = p^m \), where \( p \) is a prime. Any linear code \( C \) of length \( n \) over \( \text{GF}(q) \) gives a subfield code \( C_{\text{GF}(p)} \) of length \( n \) over \( \text{GF}(p) \) (see Section II). The objective of this paper is to determine the parameters of the subfield codes of the elliptic quadric codes and Tits ovoid codes and their duals. In particular, the weight distributions of the subfield codes of the elliptic quadric codes and Tits ovoid codes are determined. As will be seen later, some of these codes are optimal. In particular, the duals of the subfield codes of these ovoid codes are distance-optimal. The parameters of the subfield codes presented in this paper are new. The optimality and distance optimality of these codes are the motivation of this paper.

**II. SUBFIELD CODES AND THEIR PROPERTIES**

**A. Definition and basic properties**

Let \( \text{GF}(q^m) \) be a finite field with \( q^m \) elements, where \( q \) is a power of a prime and \( m \) is a positive integer. In this section, we introduce subfield codes of linear codes and prove some basic results of subfield codes.

Given an \([n, k]\) code \( C \) over \( \text{GF}(q^m) \), we construct a new \([n, k']\) code \( C^{(q)} \) over \( \text{GF}(q) \) as follows. Let \( G \) be a generator matrix of \( C \). Take a basis of \( \text{GF}(q^m) \) over \( \text{GF}(q) \). Represent each entry of \( G \) as an \( m \times 1 \) column vector of \( \text{GF}(q)^m \) with respect to this basis, and replace each entry of \( G \) with the corresponding \( m \times 1 \) column vector of \( \text{GF}(q)^m \). In this way, \( G \) is modified into a \( km \times n \) matrix over \( \text{GF}(q) \), which generates the new subfield code \( C^{(q)} \) over \( \text{GF}(q) \) with length \( n \). By definition, the dimension \( k' \) of \( C^{(q)} \) satisfies \( k' \leq mk \). We will prove that the subfield code \( C^{(q)} \) of \( C \) is independent of the choices of both \( G \) and the basis of \( \text{GF}(q^m) \) over \( \text{GF}(q) \). We first prove the following.

**Theorem 2.1:** For any linear code \( C \) over \( \text{GF}(q^m) \), the subfield code \( C^{(q)} \) is independent of the choice of the basis of \( \text{GF}(q^m) \) over \( \text{GF}(q) \) for any fixed generator matrix \( G \).

**Proof** Let \( C \) be an \([n, k]\) linear code over \( \text{GF}(q^m) \). Let
\[
G = \begin{bmatrix} G_1 \\ G_2 \\ \vdots \\ G_k \end{bmatrix}
\]
be a generator matrix of $C$, where each $G_i$ is a $1 \times n$ vector in $\mathbb{F}_q^{m^n}$. Choose a basis of $\mathbb{F}_q^m$ over $\mathbb{F}_q$ and expand each element in $G_i$, $1 \leq i \leq k$, under this basis as a column vector over $\mathbb{F}_q$. Then each $G_i$ is expanded as an $m \times n$ matrix $G_i^{(q)}$ over $\mathbb{F}_q$. Put

$$G^{(q)} = \begin{bmatrix} G_1^{(q)} \\ G_2^{(q)} \\ \vdots \\ G_k^{(q)} \end{bmatrix}.$$ 

Then $G^{(q)}$ is a generator matrix of the subfield code $C^{(q)}$ of $C$. Let $\alpha = \{\alpha_1, \alpha_2, \cdots, \alpha_m\}$ and $\beta = \{\beta_1, \beta_2, \cdots, \beta_m\}$ be any two bases of $\mathbb{F}_q^m$ over $\mathbb{F}_q$. Suppose that

$$(\alpha_1, \alpha_2, \cdots, \alpha_m) = (\beta_1, \beta_2, \cdots, \beta_m)T$$

where $T$ is an $m \times m$ invertible matrix over $\mathbb{F}_q$. Denote the corresponding subfield codes of $C$ under the two bases $\alpha$ and $\beta$ as $C^{(q)}_\alpha$ and $C^{(q)}_\beta$, respectively. The generator matrix $G^{(q)}_\alpha$ of $C^{(q)}_\alpha$ and the generator matrix $G^{(q)}_\beta$ of $C^{(q)}_\beta$ satisfy

$$G^{(q)}_\alpha = \begin{bmatrix} T & G^{(q)}_\beta \\ & \ddots \\ & & T \end{bmatrix}.$$ 

Hence, $C^{(q)}_\alpha$ and $C^{(q)}_\beta$ are the same subspace as $T$ is invertible. Then the desired conclusion follows.

We will prove that the subfield code $C^{(q)}$ is also independent of the choice of the generator matrix $G$. To proceed in this direction, we give a trace representation of the subfield code. The following lemma is well-known [12] and needed later.

**Lemma 2.2:** Let $\{\alpha_1, \alpha_2, \cdots, \alpha_m\}$ be a basis of $\mathbb{F}_q^m$ over $\mathbb{F}_q$. Then there exists a unique basis $\{\beta_1, \beta_2, \cdots, \beta_m\}$ such that for $1 \leq i, j \leq m$,

$$\text{Tr}_{q^m/q}(\alpha_i \beta_j) = \begin{cases} 0 & \text{for } i \neq j, \\ 1 & \text{for } i = j, \end{cases}$$

i.e. the dual basis.

**Lemma 2.2** directly yields the following.

**Lemma 2.3:** Let $\{\alpha_1, \alpha_2, \cdots, \alpha_m\}$ be a basis and $\{\beta_1, \beta_2, \cdots, \beta_m\}$ be its dual basis of $\mathbb{F}_q^m$ over $\mathbb{F}_q$. For any $a = \sum_{i=1}^m a_i \alpha_i \in \mathbb{F}_q^m$ where each $a_i \in \mathbb{F}_q$, we then have

$$a_i = \text{Tr}_{q^m/q}(a_\beta_i).$$

**Theorem 2.4:** Let $C$ be an $[n, k]$ linear code over $\mathbb{F}_q^m$ with generator matrix

$$G = \begin{bmatrix} g_{11} & g_{12} & \cdots & g_{1n} \\ g_{21} & g_{22} & \cdots & g_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ g_{k1} & g_{k2} & \cdots & g_{kn} \end{bmatrix}.$$ 

Let $\{\alpha_1, \alpha_2, \cdots, \alpha_m\}$ be a basis of $\mathbb{F}_q^m$ over $\mathbb{F}_q$. Then the subfield code $C^{(q)}$ of $C$ has a generator matrix

$$G^{(q)} = \begin{bmatrix} G_1^{(q)} \\ G_2^{(q)} \\ \vdots \\ G_k^{(q)} \end{bmatrix}.$$
where each
\[ G_i^{(q)} = \begin{bmatrix} Tr_{q^m/q}(g_{i1}\alpha_1) & Tr_{q^m/q}(g_{i2}\alpha_1) & \cdots & Tr_{q^m/q}(g_{in}\alpha_1) \\ Tr_{q^m/q}(g_{i1}\alpha_2) & Tr_{q^m/q}(g_{i2}\alpha_2) & \cdots & Tr_{q^m/q}(g_{in}\alpha_2) \\ \vdots & \vdots & \ddots & \vdots \\ Tr_{q^m/q}(g_{i1}\alpha_m) & Tr_{q^m/q}(g_{i2}\alpha_m) & \cdots & Tr_{q^m/q}(g_{in}\alpha_m) \end{bmatrix}. \]

**Proof** The desired conclusion follows from Lemma 2.3.

With the help of Theorem 2.4 the trace representation of subfield codes is given in the next theorem.

**Theorem 2.5**: Let \( C \) be an \([n,k]\) linear code over \( GF(q^m) \). Let \( G = \{ g_{ij} \}_{1 \leq i \leq k, 1 \leq j \leq n} \) be a generator matrix of \( C \). Then the trace representation of \( C^{(q)} \) is given by
\[
C^{(q)} = \left\{ \left( Tr_{q^m/q} \left( \sum_{i=1}^{k} a_i g_{i1} \right), \ldots, Tr_{q^m/q} \left( \sum_{i=1}^{k} a_i g_{in} \right) \right) : a_1, \ldots, a_k \in GF(q^m) \right\}.
\]

**Proof** We denote \( c = (c_1, c_2, \ldots, c_n) = xG^{(q)} \in C^{(q)} \) for any
\[
x = (x_{11}, \ldots, x_{1m}, \ldots, x_{k1}, \ldots, x_{km}) \in GF(q)^{km}.
\]
Then by Theorem 2.4
\[
c_h = \sum_{i=1}^{k} \sum_{j=1}^{m} Tr_{q^m/q}(g_{ih}x_{ij}\alpha_j) = \sum_{i=1}^{k} Tr_{q^m/q} \left( g_{ih} \sum_{j=1}^{m} x_{ij}\alpha_j \right), \ 1 \leq h \leq n,
\]
where \( \{\alpha_1, \alpha_2, \ldots, \alpha_m\} \) is a basis of \( GF(q^m) \) over \( GF(q) \). Note that
\[
GF(q^m) = \left\{ \sum_{j=1}^{m} x_{ij}\alpha_j : (x_{i1}, x_{i2}, \ldots, x_{im}) \in GF(q)^m \right\}
\]
with any fixed \( 1 \leq i \leq k \). Then the desired conclusion follows.

We are now ready to prove the following conclusion.

**Theorem 2.6**: The subfield code \( C^{(q)} \) of \( C \) over \( GF(q^m) \) is also independent of the choice of the generator matrix \( G \).

**Proof** Let \( G \) and \( G' \) be two generator matrices of an \([n,k]\) code \( C \) over \( GF(q^m) \). Then there exists a \( k \times k \) invertible matrix \( T \) over \( GF(q^m) \) such that \( G' = TG \). Let \( C_{G}^{(q)} \) and \( C_{G'}^{(q)} \) denote the subfield codes with respect to the generator matrices \( G \) and \( G' \), respectively. For any \( (a'_1, a'_2, \ldots, a'_k) \in GF(q^m)^k \), define
\[
(a_1, a_2, \ldots, a_k) = (a'_1, a'_2, \ldots, a'_k)T.
\]
Note that \( T \) is invertible. When \( (a'_1, a'_2, \ldots, a'_k) \) runs over \( GF(q^m)^k \), so does \( (a_1, a_2, \ldots, a_k) \). It then follows from Theorem 2.5 that
\[
C_{G'}^{(q)} = \left\{ \left( Tr_{q^m/q} \left( \sum_{i=1}^{k} a'_i g_{i1} \right), \ldots, Tr_{q^m/q} \left( \sum_{i=1}^{k} a'_i g_{in} \right) \right) : a'_1, \ldots, a'_k \in GF(q^m) \right\} = C_{G^{(q)}} = C^{(q)}.
\]
This completes the proof.

Summarizing Theorems 2.5 and 2.6, we conclude that the subfield code \( C^{(q)} \) over \( GF(q) \) of a linear code \( C \) over \( GF(q^m) \) is independent of the choices of both \( G \) and the basis of \( GF(q^m) \) over \( GF(q) \). So is the dual code \( C^{(q)\perp} \).
B. Relations among $C$, $C^\perp$, $C^{(q)}$ and $C^{(q)\perp}$

Denote by $C^\perp$ and $C^{(q)\perp}$ the dual codes of $C$ and its subfield code $C^{(q)}$, respectively. Let $C^{(q)}$ denote the subfield code of $C$. Since the dimensions of $C^{(q)\perp}$ and $C^{(q)\perp}$ vary from case to case, there may not be a general relation between the two codes $C^{(q)}$ and $C^{(q)\perp}$.

A relationship between the minimal distance of $C^\perp$ and that of $C^{(q)\perp}$ is given as follows.

**Theorem 2.7:** Let $C$ be an $[n, k]$ linear code over $GF(q^m)$. Then the minimal distance $d^\perp$ of $C^\perp$ and the minimal distance $d^{(q)\perp}$ of $C^{(q)\perp}$ satisfy

$$d^{(q)\perp} \geq d^\perp.$$  

**Proof** Let $G = [g_{ij}]_{1 \leq i \leq k, 1 \leq j \leq n}$ be a generator matrix of $C$. Let $G^{(q)} = [g^{(q)}_{ij}]$ be a generator matrix of $C^{(q)}$ given in Theorem 2.4. Then $G^{(q)}$ is also a parity-check matrix of $C^{(q)\perp}$. This implies that there exist $b_1, b_2, \ldots, b_{d^{(q)\perp}} \in GF(q)^*$ and integers $1 \leq j_1 < j_2 < \cdots < j_{d^{(q)\perp}} \leq n$ such that

$$d^{(q)\perp} = \sum_{h=1}^{d^{(q)\perp}} b_h \text{Tr}_{q^m/q}(g_{ij_h} \alpha_l) = \text{Tr}_{q^m/q} \left( \sum_{h=1}^{d^{(q)\perp}} b_h g_{ij_h} \alpha_l \right) = 0$$

for all $1 \leq i \leq k$ and $1 \leq l \leq m$, where $\{\alpha_1, \alpha_2, \cdots, \alpha_m\}$ is a basis of $GF(q^m)$ over $GF(q)$. Hence

$$\sum_{l=1}^{m} \text{Tr}_{q^m/q} \left( \sum_{h=1}^{d^{(q)\perp}} b_h g_{ij_h} (u_l \alpha_l) \right) = \text{Tr}_{q^m/q} \left( \left( \sum_{h=1}^{d^{(q)\perp}} b_h g_{ij_h} \right) \sum_{l=1}^{m} u_l \alpha_l \right) = 0$$

for all $1 \leq i \leq k$ and $u_l \in GF(q)$, $1 \leq l \leq m$. Consequently,

$$\sum_{h=1}^{d^{(q)\perp}} b_h g_{ij_h} = 0$$

for all $1 \leq i \leq k$. Thus there exists a codeword with Hamming weight $d^{(q)\perp}$ in $C^\perp$. Then the desired conclusion follows.

C. Equivalence of subfield codes

Two linear codes $C_1$ and $C_2$ are *permutation equivalent* if there is a permutation of coordinates which sends $C_1$ to $C_2$. If $C_1$ and $C_2$ are permutation equivalent, so are $C^\perp_1$ and $C^\perp_2$. Two permutation equivalent linear codes have the same dimension and weight distribution.

A *monomial matrix* over a field $\mathbb{F}$ is a square matrix having exactly one nonzero element of $\mathbb{F}$ in each row and column. A monomial matrix $M$ can be written either in the form $DP$ or the form $PD_1$, where $D$ and $D_1$ are diagonal matrices and $P$ is a permutation matrix.

Let $C_1$ and $C_2$ be two linear codes of the same length over $\mathbb{F}$. Then $C_1$ and $C_2$ are *monomially equivalent* if there is a monomial matrix over $\mathbb{F}$ such that $C_2 = C_1 M$. Monomial equivalence and permutation equivalence are precisely the same for binary codes. If $C_1$ and $C_2$ are monomially equivalent, then they have the same weight distribution.

Let $C$ and $C'$ be two monomially equivalent $[n, k]$ code over $GF(q^m)$. Let $G = [g_{ij}]$ and $G' = [g'_{ij}]$ be two generator matrices of $C$ and $C'$, respectively. By definition, there exist a permutation $\sigma$ of the set $\{1, 2, \cdots, n\}$ and elements $b_1, b_2, \cdots, b_n$ in $GF(q^m)^*$ such that

$$g_{ij} = b_j g'_{i\sigma(j)}$$

for all $1 \leq i \leq k$ and $1 \leq j \leq n$. It then follows that

$$\left( \text{Tr}_{q^m/q} \left( \sum_{i=1}^{k} a_i g_{i1} \right), \cdots, \text{Tr}_{q^m/q} \left( \sum_{i=1}^{k} a_i g_{in} \right) \right)$$
\[
\left( \text{Tr}_{q^m/q} \left( b_1 \left( \sum_{i=1}^{k} a_i g_{in}(1) \right) \right), \ldots, \text{Tr}_{q^m/q} \left( b_n \left( \sum_{i=1}^{k} a_i g_{in} \right) \right) \right).
\]

Then the following conclusions follow from Theorem 2.5:
- If \( C \) and \( C' \) are permutation equivalent, so are \( C^{(q)} \) and \( C'^{(q)} \).
- If all \( b_i \in GF(q)^* \), then \( C^{(q)} \) and \( C'^{(q)} \) are monomially equivalent.
However, \( C^{(q)} \) and \( C'^{(q)} \) may not be monomially equivalent even if \( C \) and \( C' \) are monomially equivalent.

D. Historical information and remarks

The subfield subcode \( C|_{GF(q)} \) of an \([n, k] \) code over \( GF(q^m) \) is the set of codewords in \( C \) each of whose components is in \( C \). Hence, the dimension of the subfield subcode \( C|_{GF(q)} \) is at most \( k \). Thus, the subfield code over \( GF(q) \) and subfield subcode over \( GF(q^m) \) of a linear code over \( GF(q^m) \) are different codes in general. Subfield codes were considered in \([7]\) and \([6]\) without using the name "subfield codes". Subfield codes were defined formally in \([5], \text{p. 5117}\) and a Magma function for subfield codes is implemented in the Magma package. The reader is warned that the subfield codes referred in \([2]\) and \([3]\) are actually subfield subcodes. These lead to a confusion. In view of the impact of the Magma computation system, we wish to follow the Magma definition of subfield subcodes.

While subfield subcodes have been well studied due to the Delsarte theorem \([8]\), little has been done for subfield codes of linear codes over finite fields. The subfield codes of several families of linear codes were considered and distance-optimal codes were constructed in \([7]\) and \([6]\). In these two references, the basic idea is to consider the subfield code of a linear code over \( GF(q^m) \) with good parameters and expect the subfield code over \( GF(q) \) to have also good parameters. In this paper, we follow the same idea, and consider the subfield codes of ovoid codes which are optimal with respect to the Griesmer bound.

III. Auxiliary results

In this section, we recall characters and some character sums over finite fields which will be needed in later sections.

Let \( p \) be a prime and \( q = p^m \). Let \( GF(q) \) be the finite field with \( q \) elements and \( \alpha \) a primitive element of \( GF(q) \). Let \( \text{Tr}_{q/p} \) denote the trace function from \( GF(q) \) to \( GF(p) \) given by

\[
\text{Tr}_{q/p}(x) = \sum_{i=0}^{m-1} x^{p^i}, \quad x \in GF(q).
\]

Denote \( \zeta_p \) as the primitive \( p \)-th root of complex unity.

An additive character of \( GF(q) \) is a function \( \chi : (GF(q), +) \rightarrow \mathbb{C}^* \) such that

\[
\chi(x + y) = \chi(x)\chi(y), \quad x, y \in GF(q),
\]

where \( \mathbb{C}^* \) denotes the set of all nonzero complex numbers. For any \( a \in GF(q) \), the function

\[
\chi_a(x) = \zeta_p^{\text{Tr}_{q/p}(ax)}, \quad x \in GF(q),
\]

defines an additive character of \( GF(q) \). In addition, \( \{\chi_a : a \in GF(q)\} \) is a group consisting of all the additive characters of \( GF(q) \). If \( a = 0 \), we have \( \chi_0(x) = 1 \) for all \( x \in GF(q) \) and \( \chi_0 \) is referred to as the trivial additive character of \( GF(q) \). If \( a = 1 \), we call \( \chi_1 \) the canonical additive character of \( GF(q) \). Clearly, \( \chi_a(x) = \chi_1(ax) \). The orthogonality relation of additive characters is given by

\[
\sum_{x \in GF(q)} \chi_1(ax) = \begin{cases} q & \text{for } a = 0, \\ 0 & \text{for } a \in GF(q)^*. \end{cases}
\]

Let \( GF(q)^* = GF(q) \setminus \{0\} \). A character \( \psi \) of the multiplicative group \( GF(q)^* \) is a function from \( GF(q)^* \) to \( \mathbb{C}^* \) such that \( \psi(xy) = \psi(x)\psi(y) \) for all \( (x, y) \in GF(q) \times GF(q) \). Define the multiplication of
two characters $\psi, \psi'$ by $(\psi \psi')(x) = \psi(x)\psi'(x)$ for $x \in \text{GF}(q)^*$. All the characters of $\text{GF}(q)^*$ are given by

$$\psi_j(\alpha^k) = \zeta_q^{jk}$$

where $0 \leq j \leq q - 2$. Then all these $\psi_j$, $0 \leq j \leq q - 2$, form a group under the multiplication of characters and are called multiplicative characters of $\text{GF}(q)$. In particular, $\psi_0$ is called the trivial multiplicative character and $\eta := \psi_{(q-1)/2}$ is referred to as the quadratic multiplicative character of $\text{GF}(q)$. The orthogonality relation of multiplicative characters is given by

$$\sum_{x \in \text{GF}(q)^*} \psi_j(x) = \begin{cases} q - 1 & \text{for } j = 0, \\ 0 & \text{for } j \neq 0. \end{cases}$$

For an additive character $\chi$ and a multiplicative character $\psi$ of $\text{GF}(q)$, the Gauss sum $G(\psi, \chi)$ over $\text{GF}(q)$ is defined by

$$G(\psi, \chi) = \sum_{x \in \text{GF}(q)^*} \psi(x)\chi(x).$$

We call $G(\eta, \chi)$ the quadratic Gauss sum over $\text{GF}(q)$ for nontrivial $\chi$. The value of the quadratic Gauss sum is known as follows.

**Lemma 3.1:** [12, Th. 5.15] Let $q = p^m$ with $p$ odd. Let $\chi$ be the canonical additive character of $\text{GF}(q)$. Then

$$G(\eta, \chi) = (-1)^{m-1}(\sqrt{-1})^{(m-1)^2} \sqrt{q}$$

$$= \begin{cases} (-1)^{m-1}(\sqrt{q}) & \text{for } p \equiv 1 \pmod{4}, \\ (-1)^{m-1}(\sqrt{-1})^{m} \sqrt{q} & \text{for } p \equiv 3 \pmod{4}. \end{cases}$$

Let $\chi$ be a nontrivial character of $\text{GF}(q)$ and let $f \in \text{GF}(q)[x]$ be a polynomial of positive degree. The character sums of the form

$$\sum_{c \in \text{GF}(q)} \chi(f(c))$$

are referred to as Weil sums. The problem of evaluating such character sums explicitly is very difficult in general. In certain special cases, Weil sums can be treated (see [12, Section 4 in Chapter 5]). If $f$ is a quadratic polynomial, the Weil sum has an interesting relationship with quadratic Gauss sums, which is described in the following lemma.

**Lemma 3.2:** [12, Th. 5.33] Let $\chi$ be a nontrivial additive character of $\text{GF}(q)$ with $q$ odd, and let $f(x) = a_2x^2 + a_1x + a_0 \in \text{GF}(q)[x]$ with $a_2 \neq 0$. Then

$$\sum_{c \in \text{GF}(q)} \chi(f(c)) = \chi(a_0 - a_2^2(4a_2)^{-1})\eta(a_2)G(\eta, \chi).$$

### IV. The Subfield Codes of the Elliptic Quadric Codes

Let $q = p^m > 2$ with $p$ a prime. Let $\mathcal{V}$ be the elliptic quadric defined by

$$\mathcal{V} = \{(0, 0, 1, 0)\} \cup \{(x, y, x^2 + xy + ay^2, 1) : x, y \in \text{GF}(q)\},$$

where $a \in \text{GF}(q)$ is such that the polynomial $x^2 + x + a$ has no root in $\text{GF}(q)$. Our task in this section is to study the subfield code $\mathcal{C}_\mathcal{V}^{(p)}$ of the elliptic quadric code $\mathcal{C}_\mathcal{V}$.

Let $\alpha$ be a primitive element of $\text{GF}(q)$. Denote

$$f_1(x, y) = x, \ f_2(x, y) = y, \ f_3(x, y) = x^2 + xy + ay^2$$
and
\[ G_{x,y} = \begin{bmatrix} f_1(x, y) \\ f_2(x, y) \\ f_3(x, y) \\ 1 \end{bmatrix}_{(x,y) \in \mathbb{G}(q)^2} \]

which is a \( 4 \times q^2 \) matrix over \( \mathbb{G}(q) \). Let \( \mathcal{C}_V \) be the linear code over \( \mathbb{G}(q) \) with generator matrix
\[ G_V = \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}. \]

Combining the definition of \( G_V \) and Theorem 4.1 yields the following trace representation of \( \mathcal{C}_V^{(p)} \):
\[ \mathcal{C}_V^{(p)} = \{ (\text{Tr}_{q/p}(uf_1(x, y) + vf_2(x, y) + wf_3(x, y) + h))_{(x,y) \in \mathbb{G}(q)^2}, \text{Tr}_{q/p}(w) : u, v, w \in \mathbb{G}(q), h \in \mathbb{G}(p) \} \]
\[ = \{ (\text{Tr}_{q/p}(g(x, y)) + h)_{(x,y) \in \mathbb{G}(q)^2}, \text{Tr}_{q/p}(w) : u, v, w \in \mathbb{G}(q), h \in \mathbb{G}(p) \} \]
where \( g(x, y) := uf_1(x, y) + vf_2(x, y) + wf_3(x, y) = ux + vy + wx^2 + wxy + wy^2. \)

The weight distribution of \( \mathcal{C}_V^{(p)} \) will be settled separately in the following two cases.

A. The case \( p = 2 \)

In the case that \( p = 2 \) and \( q = 2^m > 2 \), the weight distribution of \( \mathcal{C}_V^{(p)} \) is documented in the following theorem.

Theorem 4.1: Let \( p = 2 \) and \( m > 1 \). Then \( \mathcal{C}_V^{(p)} \) is a six-weight binary linear code with parameters \( [2^{2m} + 1, 3m + 1, 2^{2m-1} - 2^{m-1}] \) and the weight distribution in Table I. Its dual \( \mathcal{C}_V^{(p)\perp} \) has parameters \( [2^{2m} + 1, 2^{2m} - 3m, 4] \).

| Weight | Multiplicity |
|--------|-------------|
| 0      | 1           |
| \( 2^{2m} \) | 1           |
| \( 2^{2m-1} - 2^{m-1} \) | 2\( (2^{2m} - 1) \) |
| \( 2^{2m-1} + 2^{m-1} \) | 2\( (2^{2m} - 1) \) |
| \( 2^{2m-1} - 2^{m-1} + 1 \) | 2\( 3^{m-1} \) |
| \( 2^{2m-1} + 2^{m-1} + 1 \) | 2\( 3^{m-1} \) |

Proof Firstly, assume that \( (u, v, w) \neq (0, 0, 0) \). Denote
\[ N_0(u, v, w) = \#\{ (x, y) \in \mathbb{G}(q)^2 : \text{Tr}_{q/p}(g(x, y)) = 0 \} \]
and
\[ N_1(u, v, w) = \#\{ (x, y) \in \mathbb{G}(q)^2 : \text{Tr}_{q/p}(g(x, y)) = 1 \}. \]

By the orthogonality relation of additive characters, we have
\[ 2N_0(u, v, w) = \sum_{(x,y) \in \mathbb{G}(q)^2} \sum_{z \in \mathbb{G}(2)} (-1)^z \text{Tr}(g(x, y)) \]
where

\[
q^2 + \sum_{(x,y)\in\text{GF}(q)^2} (-1)^\text{Tr}(g(x,y)).
\]  

(5)

We discuss the value of \(N_0(u, v, w)\) in the following cases.

1) If \(w = 0\), we have \(g(x, y) = ux + vy\). Since \((u, v) \neq (0, 0)\), we deduce that \(N_0(u, v, w) = q^2/2 = 2^{2m-1}\).

2) If \(w \neq 0\), we denote

\[
\Delta = \sum_{(x,y)\in\text{GF}(q)^2} (-1)^\text{Tr}(g(x,y)).
\]

Then

\[
\Delta^2 = \left( \sum_{(x,y)\in\text{GF}(q)^2} (-1)^\text{Tr}_{2m/2}(g(x,y)) \right) \left( \sum_{(x,y)\in\text{GF}(q)^2} (-1)^\text{Tr}_{2m/2}(g(x,y)) \right)
\]

\[
= \sum_{(x,y)\in\text{GF}(q)^2} \sum_{(x_1,y_1)\in\text{GF}(q)^2} (-1)^\text{Tr}_{2m/2}(g(x_1,y_1)-g(x,y))
\]

\[
= \sum_{(x,y)\in\text{GF}(q)^2} (-1)^\text{Tr}_{2m/2}(g(x+A,y+B)-g(x,y))
\]

\[
= q^2 - \sum_{(A,B)\in\text{GF}(q)^2\setminus\{0,0\}} \sum_{(x,y)\in\text{GF}(q)^2} (-1)^\text{Tr}_{2m/2}(g(x+A,y+B)-g(x,y))
\]

\[
= q^2 - \sum_{(A,B)\in\text{GF}(q)^2\setminus\{0,0\}} \sum_{(x,y)\in\text{GF}(q)^2} (-1)^\text{Tr}_{2m/2}(uA+vB+wA^2+wAB^2+wBx+wAy)
\]

\[
= q^2 - \sum_{(A,B)\in\text{GF}(q)^2\setminus\{0,0\}} \sum_{x\in\text{GF}(q)} (-1)^\text{Tr}_{2m/2}(wBx)
\]

\[
\times \sum_{y\in\text{GF}(q)} (-1)^\text{Tr}_{2m/2}(wAy)
\]

\[
= q^2.
\]

where we used the variable substitution \(x_1 = x + A\), \(y_1 = y + B\) in the third equality and the last equality holds due to the orthogonality relation of additive characters. By Equation (5), \(\Delta\) is an integer. Hence \(\Delta = \pm q\) and Equation (5) implies

\[
N_0(u, v, w) = 2^{2m-1} \pm 2^{m-1}.
\]

Combining the two cases above yields

\[
N_0(u, v, w) = \begin{cases} 
2^{2m-1} & \text{for } w = 0, \\
2^{2m-1} \pm 2^{m-1} & \text{for } w \neq 0,
\end{cases}
\]

where \((u, v, w) \neq (0, 0, 0)\) and \(N_1(u, v, w) = 2^{2m} - N_0(u, v, w)\).

For any codeword \(c(u, v, w, h) := \left( (\text{Tr}_{2m/2}(g(x,y)) + h)_{(x,y)\in\text{GF}(2m)^2}, \text{Tr}_{2m/2}(w) \right) \in C^{(2)}_V\), by the foregoing discussions we deduce that

\[
\text{wt}(c(u, v, w, h)) = \begin{cases} 
0 & \text{for } (u, v, w, h) = (0, 0, 0, 0) \\
2^{2m} & \text{for } (u, v, w, h) = (0, 0, 0, 1) \\
N_1(u, v, w) & \text{for } w = h = 0, (u, v) \neq (0, 0) \\
N_0(u, v, w) & \text{for } w = 0, h = 1, (u, v) \neq (0, 0) \\
N_1(u, v, w) & \text{for } h = 0, w \neq 0, \text{Tr}_{2m/2}(w) = 0, (u, v) \in \text{GF}(q)^2 \\
N_0(u, v, w) & \text{for } h = 1, w \neq 0, \text{Tr}_{2m/2}(w) = 0, (u, v) \in \text{GF}(q)^2 \\
N_1(u, v, w) + 1 & \text{for } h = 0, \text{Tr}_{2m/2}(w) \neq 0, (u, v) \in \text{GF}(q)^2 \\
N_0(u, v, w) + 1 & \text{for } h = 1, \text{Tr}_{2m/2}(w) \neq 0, (u, v) \in \text{GF}(q)^2 
\end{cases}
\]
where the frequency of each weight is very easy to derive. Since $A_{0} = 1$, the dimension of $C_{V}^{(2)}$ is $3m + 1$.

Note that $C_{V}^{(2)\perp}$ has length $2^{2m} + 1$ and dimension $2^{2m} - 3m$. It follows from Theorems 2.7 and 1.1 that the minimal distance $d^{(2)\perp}$ of $C_{V}^{(2)\perp}$ satisfies $d^{(2)\perp} \geq 4$. By the sphere-packing bound, we have

$$2^{2m+1} \geq 2^{2m}m - 3m \left\lceil \frac{d^{(2)\perp} - 1}{2} \right\rceil \left( \frac{2^{2m} + 1}{2^{m}} \right),$$

which implies that $d^{(2)\perp} \leq 4$, where $\lfloor x \rfloor$ is the floor function. Thus $d^{(2)\perp} = 4$. Then the desired conclusions follow.

By the proof of Theorem 4.1, the weight distribution of $C_{V}^{(2)}$ is independent of $a$. However, this will not be true for $C_{V}^{(p)}$ for odd $p$.

B. The case $p > 2$

In the following, we investigate the weight distributions of $C_{V}^{(p)}$ for $p > 2$. We first present some lemmas below.

Lemma 4.2: Let $q$ be odd and $\eta$ the quadratic multiplicative character of $GF(q)$. Let $x^2 + x + a$ be irreducible over $GF(q)$. Then $\eta(a - 4^{-1}) = (-1)^{(q+1)/2}$.

Proof Let $\alpha$ be a primitive element of $GF(q)$. It is easily seen that

$$\eta(-1) = \begin{cases} -1 & \text{for } q \equiv 3 \pmod{4}, \\ 1 & \text{for } q \equiv 1 \pmod{4}. \end{cases}$$

For $q \equiv 3 \pmod{4}$, suppose that $\eta(a - 4^{-1}) = -1$. Then $a - 4^{-1} = \alpha^{2j+1}$ for some $0 \leq j \leq \frac{q-3}{2}$. The discriminant of $x^2 + x + a = 0$ equals $-\alpha^{2j+1}$ which is a square in $GF(q)$ as $\eta(-1) = -1$. This contradicts with the fact that $x^2 + x + a$ is irreducible. Hence, $\eta(a - 4^{-1}) = 1$.

For $q \equiv 1 \pmod{4}$, suppose that $\eta(a - 4^{-1}) = 1$. Then $a - 4^{-1} = \alpha^{2j}$ for some $0 \leq j \leq \frac{q-3}{2}$. The discriminant of $x^2 + x + a = 0$ equals $-\alpha^{2j}$ which is a square in $GF(q)$ as $\eta(-1) = 1$. This contradicts with the fact that $x^2 + x + a$ is irreducible. Hence, $\eta(a - 4^{-1}) = -1$. Then the desired conclusions follow.

Lemma 4.3: Let $q$ be odd and $\eta$ the quadratic multiplicative character of $GF(q)$. Let $x^2 + x + a$ be reducible over $GF(q)$ and $a \neq 4^{-1}$. Then $\eta(a - 4^{-1}) = (-1)^{(q+1)/2}$.

Proof Since $x^2 + x + a$ is reducible over $GF(q)$ and $a \neq 4^{-1}$, we have $a = 4^{-1} - b^2$ for some $b \in GF(q)^*$. Hence, $\eta(a - 4^{-1}) = \eta(-b^2) = \eta(-1)$. Recall that

$$\eta(-1) = \begin{cases} -1 & \text{for } q \equiv 3 \pmod{4}, \\ 1 & \text{for } q \equiv 1 \pmod{4}. \end{cases}$$

Then the desired conclusion follows.

Lemma 4.4: Let $q = p^m$ with $p$ odd. Then $(\frac{p-1}{2})^2m + \frac{q+1}{2}$ is an odd integer.
Proof} Note that \((\frac{q-1}{2})^2 m + \frac{q+1}{2} = \frac{p^2 m - 2pm + 2q + m}{4} + 2.\) Denote \(s = p^2 m - 2pm + 2q + m + 2.\) We discuss the value of \(s\) in two cases.

1) Let \(p \equiv 1 \pmod{4}\). Assume that \(p = 4t + 1\) for some positive integer \(t\). Then
\[
s = (4t + 1)^2 m - 2(4t + 1)m + 2(4t + 1)^m + m + 2 \\
= 16t^2m + 2(4t + 1)^m + 2 \\
\equiv 4 \pmod{8}.
\]

2) Let \(p \equiv 3 \pmod{4}\). Assume that \(p = 4t + 3\) for some nonnegative integer \(t\). Then
\[
s = (4t + 3)^2 m - 2(4t + 3)m + 2(4t + 3)^m + m + 2 \\
= 16t^2m + 16tm + 2(4t + 3)^m + 4m + 2 \\
\equiv 4 \pmod{8}.
\]

Then the desired conclusion follows.

**Lemma 4.5** Let \(q = p^m\) with \(p\) odd. Then \((\frac{p-1}{2})^2 m + \frac{q+1}{2}\) is an even integer.

**Proof** The proof is similar to that of Lemma 4.4 and is omitted.

The weight distributions of \(C^{(p)}_V\) are given in three cases according to different choices of \(a\) as follows.

**Theorem 4.6** Let \(p > 2, m > 1\) and \(a \in \text{GF}(q)\) such that \(x^2 + x + a\) has no root in \(\text{GF}(q)\). Then \(C^{(p)}_V\) is a six-weight \(p\)-ary linear code with parameters \([p^{2m} + 1, 3m + 1, p^{2m-1}(p - 1) - p^{m-1}]\) and the weight distribution in Table II. Its dual \(C^{(p)}_V^⊥\) has parameters \([p^{2m} + 1, p^{2m} - 3m, 4]\).

| Weight | Multiplicity |
|--------|--------------|
| \(p^{2m}\) | \(p - 1\) |
| \((p^{2m-1} + p^{m-1})(p - 1)\) | \(p(p^{2m} - 1)\) |
| \((p^{2m-1} + p^{m-1})(p - 1) - p^{m-1}\) | \(p^2(p^{2m-1} - 1)\) |
| \((p^{2m-1} + p^{m-1})(p - 1) - p^{m-1} + 1\) | \(p^3(p^{2m-1} - 1)(p - 1)\) |

**Proof** Let \(\chi\) be the canonical additive character of \(\text{GF}(q)\). Denote
\[
N(u, v, w, h) = \#\{(x, y) \in \text{GF}(q)^2 : \text{Tr}_{q/p}(g(x, y)) + h = 0\}.
\]

By the orthogonality relation of additive characters, we have
\[
pN(u, v, w, h) = \sum_{(x, y) \in \text{GF}(q)^2} \sum_{z \in \text{GF}(p)} \zeta_p^{z(\text{Tr}_{q/p}(g(x, y)) + h)} \\
= q^2 + \sum_{z \in \text{GF}(p)^*} \zeta_p^{zh} \sum_{(x, y) \in \text{GF}(q)^2} \chi(zg(x, y)) \\
= q^2 + \Omega, \tag{6}
\]

where
\[
\Omega := \sum_{z \in \text{GF}(p)^*} \zeta_p^{zh} \sum_{(x, y) \in \text{GF}(q)^2} \chi(zg(x, y)).
\]
Recall that $g(x, y) = uf_1(x, y) + vf_2(x, y) + wf_3(x, y) = ux + vy + wx^2 + wxy + way^2$. Then we have

$$
\Omega = \sum_{z \in GF(p)^*} \zeta^z \sum_{(x, y) \in GF(q)^2} \chi(z(ux + vy + wx^2 + wxy + way^2))
= \sum_{z \in GF(p)^*} \zeta^z \sum_{y \in GF(q)} \chi(zway^2 + zvy) \sum_{x \in GF(q)} \chi(zwx^2 + (zu + zwy)x). \tag{7}
$$

If $(u, v, w) \neq (0, 0, 0)$, we discuss the value of $\Omega$ in the following cases.

1) Assume that $w \neq 0$. Using Lemma 3.2, we get that

$$
\sum_{x \in GF(q)} \chi(zwx^2 + (zu + zwy)x) = \chi\left(- (zu + zwy)(4zw)^{-1}\right) \eta(zw) G(\eta, \chi) = \chi\left(4^{-1}zwy^2 - 2^{-1}uzy - z(4w)^{-1}u^2\right) \eta(zw) G(\eta, \chi). \tag{8}
$$

Note that $a - 4^{-1} \neq 0$ as $x^2 + x + a$ is irreducible over $GF(q)$. Combining Equations (7) and (8) yields that

$$
\Omega = G(\eta, \chi) \sum_{z \in GF(p)^*} \zeta^z \eta(zw) \sum_{y \in GF(q)} \chi\left((zwa - 4^{-1}zw)y^2 + (zv - 2^{-1}uz)y - z(4w)^{-1}u^2\right)
\times \eta(zwa - 4^{-1}zw)
\sum_{z \in GF(p)^*} \zeta^z \eta(zw)^2 \chi\left(- z(4w)^{-1}u^2 - (zv - 2^{-1}uz)^2(4zwa - zw)^{-1}\right)
\eta(a - 4^{-1})
\sum_{z \in GF(p)^*} \zeta^z \chi\left(- zw^{-1}(4^{-1}u^2 + (v - 2^{-1}u)^2(4a - 1)^{-1})\right)
= \begin{cases}
G(\eta, \chi)^2 \eta(a - 4^{-1}) \sum_{z \in GF(p)^*} \zeta^z \chi(cz) & \text{for } (u, v) = (0, 0), \\
G(\eta, \chi)^2 \eta(a - 4^{-1}) \sum_{z \in GF(p)^*} \zeta^z \chi(cz) & \text{for } (u, v) \neq (0, 0), \\
(-1)^{(\frac{p-1}{2})m+\frac{m+1}{2}} q \sum_{z \in GF(p)^*} \zeta^z \chi(cz) & \text{for } (u, v) = (0, 0), \\
(-1)^{(\frac{p-1}{2})m+\frac{m+1}{2}} q \sum_{z \in GF(p)^*} \zeta^z \chi(cz) & \text{for } (u, v) \neq (0, 0),
\end{cases}
= \begin{cases}
-q \sum_{z \in GF(p)^*} \zeta^z \chi(cz) & \text{for } (u, v) = (0, 0), \\
-q \sum_{z \in GF(p)^*} \zeta^z \chi(cz) & \text{for } (u, v) \neq (0, 0),
\end{cases}
$$

where $c := - w^{-1}(4^{-1}u^2 + (v - 2^{-1}u)^2(4a - 1)^{-1})$ for $u, v \neq (0, 0)$, the second equality holds due to Lemma 3.2 and the last two equalities hold by Lemmas 3.1, 4.2, and 4.4. Then we further have

$$
\Omega = \begin{cases}
-q(p - 1) & \text{for } (u, v) = (0, 0), h = 0 \\
q & \text{for } (u, v) = (0, 0), h \neq 0 \\
-q \sum_{z \in GF(p)^*} \zeta^z \chi(Tr_{q/p}(c)z) & \text{for } (u, v) \neq (0, 0), h = 0 \\
-q \sum_{z \in GF(p)^*} \zeta^z \chi((h + Tr_{q/p}(c))z) & \text{for } (u, v) \neq (0, 0), h \neq 0
\end{cases}
= \begin{cases}
-q(p - 1) & \text{for } (u, v) = (0, 0), h = 0 \\
q & \text{for } (u, v) = (0, 0), h \neq 0 \\
-q(p - 1) & \text{for } (u, v) \neq (0, 0), h = 0, \text{Tr}_{q/p}(c) = 0 \\
q & \text{for } (u, v) \neq (0, 0), h = 0, \text{Tr}_{q/p}(c) \neq 0 \\
-q(p - 1) & \text{for } (u, v) \neq (0, 0), h \neq 0, \text{Tr}_{q/p}(c) = 0 \\
q & \text{for } (u, v) \neq (0, 0), h \neq 0, \text{Tr}_{q/p}(c) \neq 0
\end{cases}
$$
By Equation (6) and the discussions above, we deduce that

\[ c \]

2) Assume that

For any codeword

when \((u, v, w, h)\) runs through \(\text{GF}(q) \times \text{GF}(q) \times \text{GF}(q)^* \times \text{GF}(p)\).

Then Equation (7) implies

\[
\Omega = \sum_{z \in \text{GF}(p)^*} \sum_{(x, y) \in \text{GF}(q)^2} \chi(z(ux + vy))
\]

\[
= \sum_{z \in \text{GF}(p)^*} \sum_{x \in \text{GF}(q)^2} \chi(zux) \sum_{x \in \text{GF}(q)^2} \chi(zvy)
\]

= 0

as \((u, v) \neq (0, 0)\).

By Equation (6) and the discussions above, we deduce that

\[
N(u, v, w, h) = \begin{cases} 
  p^{2m} & \text{for } (u, v, w, h) = (0, 0, 0, 0), \\
  0 & \text{for } (u, v, w) = (0, 0, 0, 0), \ h \neq 0, \\
  p^{2m-1} & \text{for } (u, v) \neq (0, 0) \text{ and } w = 0, \\
  p^{2m-1} - p^{m-1}(p-1) & \text{for } (u, v) = (0, 0), \ h = 0, \ w \neq 0 \text{ or } (u, v) \neq (0, 0), \ h + \text{Tr}_{q/p}(c) = 0, \ w \neq 0, \\
  p^{2m-1} + p^{m-1} & \text{for } (u, v) = (0, 0), \ h = 0, \ w = 0.
\end{cases}
\]

where \(c \in \text{GF}(q)^*\) is defined as above.

For any codeword

\[
c(u, v, w, h) = \left( (\text{Tr}_{p^m/p}(g(x, y)) + h)_{(x, y) \in \text{GF}(p^m)^2}, \text{Tr}_{p^m/p}(w) \right) \in C^{(p)}_V,
\]

by the discussions above we deduce that

\[
\text{wt}(c(u, v, w, h)) = \begin{cases} 
  0 & \text{for } (u, v, w, h) = (0, 0, 0, 0) \\
  p^{2m} & \text{for } (u, v, w) = (0, 0, 0, 0), \ h \neq 0, \\
  p^{2m-1} - p^{m-1}(p-1) & \text{for } (u, v) \neq (0, 0) \text{ and } w = 0, \\
  (p^{2m-1} + p^{m-1})(p-1) & \text{for } (u, v) = (0, 0), \ h = 0, \ w \neq 0, \ \text{Tr}_{p^m/p}(w) = 0 \text{ or } (u, v) \neq (0, 0), \ h + \text{Tr}_{q/p}(c) = 0, \ w \neq 0, \ \text{Tr}_{p^m/p}(w) = 0 \\
  p^{2m-1} - p^{m-1} + 1 & \text{for } (u, v) = (0, 0), \ h \neq 0, \ w \neq 0, \ \text{Tr}_{p^m/p}(w) = 0 \text{ or } (u, v) \neq (0, 0), \ h + \text{Tr}_{q/p}(c) = 0, \ \text{Tr}_{p^m/p}(w) = 0 \\
  p^{2m-1}(p-1) - p^{m-1} & \text{for } (u, v) = (0, 0), \ h = 0, \ \text{Tr}_{p^m/p}(w) \neq 0 \text{ or } (u, v) \neq (0, 0), \ h + \text{Tr}_{q/p}(c) \neq 0, \ \text{Tr}_{p^m/p}(w) \neq 0 \\
  0 & \text{with } 1 \text{ time,} \\
  p^{2m} & \text{with } p-1 \text{ times,} \\
  p^{2m-1}(p-1) & \text{with } p(p^{2m} - 1) \text{ times,} \\
  (p^{2m-1} + p^{m-1})(p-1) & \text{with } p^{2m}(p^{m-1} - 1) \text{ times,} \\
  p^{2m-1} - p^{m-1} + 1 & \text{with } p^{2m}(p^{m-1} - 1)(p-1) \text{ times,} \\
  (p^{2m-1} + p^{m-1})(p-1) & \text{with } p^{3m-1}(p-1) \text{ times,} \\
  p^{2m-1}(p-1) - p^{m-1} + 1 & \text{with } p^{3m-1}(p-1)^2 \text{ times,}
\end{cases}
\]

when \((u, v, w, h)\) runs through \(\text{GF}(q) \times \text{GF}(q) \times \text{GF}(q) \times \text{GF}(p)\). Note that the dimension of \(C^{(p)}_V\) is \(3m + 1\) as \(A_0 = 1\).
Note that $C_v^{(p)\perp}$ is of length $p^{2m} + 1$ and dimension $p^{2m} - 3m$. It follows from Theorems 2.7 and 1.1 that the minimal distance $d^{(p)\perp}$ of $C_v^{(p)\perp}$ satisfies $d^{(p)\perp} \geq 4$. By the sphere-packing bound, we have

\[
p^{2m+1} \geq p^{2m-3m} \left( \frac{\lfloor d^{(p)\perp} \rfloor}{\sum_{i=0}^{p-1} (p-1)^i (p^{2m} + 1)} \right),
\]

which implies that $d^{(p)\perp} \leq 4$, where $[x]$ is the floor function. Thus $d^{(p)\perp} = 4$. The proof is now completed.

**Theorem 4.7:** Let $p > 2$, $m > 1$ and $a \in \text{GF}(q)$ such that $x^2 + x + a$ is reducible over $\text{GF}(q)$ and $a \neq 4^{-1}$. Then $C_v^{(p)}$ is a six-weight $p$-ary linear code with parameters $[p^{2m} + 1, 3m + 1, (p^{2m-1} - p^{m-1})(p - 1)]$ and the weight distribution in Table III.

### Table III

| Weight                  | Multiplicity |
|-------------------------|--------------|
| $p^{2m}$                | 1            |
| $p^{2m-1}(p-1)$         | $p - 1$      |
| $(p^{2m-1} - p^{m-1})(p-1)$ | $p^{2m}(p^{m-1} - 1)$ |
| $p^{2m-1}(p-1) + p^{m-1}$ | $p^{2m}(p^{m-1} - 1)(p-1)$ |
| $(p^{2m-1} - p^{m-1})(p-1) + 1$ | $p^{3m-1}(p-1)$ |
| $p^{2m-1}(p-1) + p^{m-1} + 1$ | $p^{3m-1}(p-1)^2$ |

**Proof** The proof of this theorem and that of Theorem 4.6 are almost exactly the same except for using Lemmas 4.3 and 4.5 instead of Lemmas 4.2 and 4.4. We omit the details of the proof here.

**Lemma 4.8:** Let $q = p^m$ with $p$ an odd prime. Then the following statements hold.

1)

\[
\# \{w \in \text{GF}(q)^*: \eta(w) = 1 \text{ and } \text{Tr}_{q/p}(w) = 0\} = \begin{cases} \frac{p^{m-1} - 1 - (p-1)p^{m-2}}{2} & \text{for even } m, \\ \frac{p^{m-1} - 1}{2} & \text{for odd } m. \end{cases}
\]

2)

\[
\# \{w \in \text{GF}(q)^*: \eta(w) = 1 \text{ and } \text{Tr}_{q/p}(w) \neq 0\} = \begin{cases} \frac{(p-1)(p^{m-1} - p^{m-2})}{2} & \text{for even } m, \\ \frac{p^{m-1}(p-1)}{2} & \text{for odd } m. \end{cases}
\]

3)

\[
\# \{w \in \text{GF}(q)^*: \eta(w) = -1 \text{ and } \text{Tr}_{q/p}(w) = 0\} = \begin{cases} \frac{p^{m-1} - 1 + (p-1)p^{m-2}}{2} & \text{for even } m, \\ \frac{p^{m-1}}{2} & \text{for odd } m. \end{cases}
\]

4)

\[
\# \{w \in \text{GF}(q)^*: \eta(w) = -1 \text{ and } \text{Tr}_{q/p}(w) \neq 0\}
\]
Proof We only prove the first equality as the others follow directly. Let χ be the canonical additive character and α a primitive element of GF(q). Let C₀ be the cyclic group generated by α². Denote 

\[ N(w) = \frac{1}{p} \sum_{z \in GF(p)} \sum_{w \in C₀} \chi(zw) \]

\[ = \frac{1}{2^p} \sum_{z \in GF(p)} \sum_{w \in GF(q)²} \chi(zw²) \]

\[ = \frac{q-p}{2p} + \frac{1}{2p} \sum_{z \in GF(p)} \sum_{w \in GF(q)²} \chi(zw²) \]

\[ = \frac{q-p}{2p} + \frac{1}{2p} G(\eta, \chi) \sum_{z \in GF(p)} \eta(z) \]

\[ = \begin{cases} \frac{q-p}{2p} + \frac{p-1}{2p} G(\eta, \chi) & \text{for even } m \\ \frac{q-p}{2p} & \text{for odd } m \end{cases} \]

where the fifth equality comes from the orthogonality of the multiplicative characters.

**Theorem 4.9:** Let \( p > 2, m > 1 \) and \( a = 4^{-1} \). Then \( C_ν^{(p)} \) is a \( p \)-ary \( [p^{2m} + 1, 3m + 1] \) linear code with weight distributions in Tables IV and V for even \( m \) and odd \( m \), respectively.

**TABLE IV**
The weight distribution of \( C_ν^{(p)} \) for \( p > 2, \) even \( m \) and \( a = 4^{-1} \)

| Weight | Multiplicity |
|--------|--------------|
| 0      | \( p^{2m} \) |
| \( p^{2m-1}(p-1) \) | \( p^{2m-1}(p-1) + 1 \) |
| \( p^{m-1}(p-1) \left( p^m + p^{m/2}(\sqrt{-1})^{m+1} \right) \) | \( p^m \) |
| \( p^m \) | \( p^m \) |
| \( p^{m-1}(p-1) \left( p^m + p^{m/2}(\sqrt{-1})^{m+1} \right) + 1 \) | \( p^{m-1}(p-1) \left( p^m + p^{m/2}(\sqrt{-1})^{m+1} \right) \) |
| \( p^m \) | \( p^m \) |
| \( p^{m-1}(p-1) \left( p^m - p^{m/2}(\sqrt{-1})^{m+1} \right) + 1 \) | \( p^{m-1}(p-1) \left( p^m - p^{m/2}(\sqrt{-1})^{m+1} \right) \) |
| \( p^m \) | \( p^m \) |
| \( p^{m-1}(p-1) \left( p^m - p^{m/2}(\sqrt{-1})^{m+1} \right) \) | \( p^{m-1}(p-1) \left( p^m - p^{m/2}(\sqrt{-1})^{m+1} \right) \) |
| \( p^m \) | \( p^m \) |

Proof We follow the notation in the proof of Theorem 3.6, where

\[ N(u, v, w, h) = \# \{(x, y) \in GF(q)^2 : \text{Tr}_{q/p}(g(x, y)) + h = 0 \}. \]
When $a = 4^{-1}$.

If $w \neq 0$, by Equations (6), (7) and (8) and Lemma 3.2 we have

$$pN(u, v, w, h) = q^2 + \Omega,$$

where

$$\Omega = G(\eta, \chi) \sum_{z \in \text{GF}(p)^*} \zeta_p^z \eta(zw) \sum_{y \in \text{GF}(q)} \chi((zw - 4^{-1}zw)y^2 + (zw - 2^{-1}uz)y - (4w)^{-1}u^2)$$

$$= G(\eta, \chi) \sum_{z \in \text{GF}(p)^*} \zeta_p^z \eta(zw)\chi((-z(4w)^{-1}u^2)) \sum_{y \in \text{GF}(q)} \chi((zw - 2^{-1}uz)y)$$

$$= \begin{cases} 
0 & \text{for } v \neq 2^{-1}u, \\
G(\eta, \chi)q & \text{for } v = 2^{-1}u
\end{cases}$$

$$= \begin{cases} 
G(\eta, \chi)q & \text{for } v \neq 2^{-1}u, \\
G(\eta, \chi) & \text{for } v = 2^{-1}u
\end{cases}$$

When $m$ is even, we have $\eta(z) = 1$ for $z \in \text{GF}(p)^*$. When $m$ is odd, $\eta(z) = \eta'(z)$ for $z \in \text{GF}(p)^*$, where $\eta'$ denotes the quadratic multiplicative character of $\text{GF}(p)$. Let $\chi'$ denote the canonical additive character of $\text{GF}(p)$. Then we have the following.

1) When $m$ is even, we deduce that

$$\Omega = \begin{cases} 
0 & \text{for } v \neq 2^{-1}u, \\
G(\eta, \chi)q(p-1) & \text{for } v = 2^{-1}u, \ h = \text{Tr}_{q/p}(w^{-1}v^2), \ \eta(w) = 1, \\
-G(\eta, \chi)q & \text{for } v = 2^{-1}u, \ h \neq \text{Tr}_{q/p}(w^{-1}v^2), \ \eta(w) = 1, \\
-G(\eta, \chi)q(p-1) & \text{for } v = 2^{-1}u, \ h = \text{Tr}_{q/p}(w^{-1}v^2), \ \eta(w) = -1, \\
G(\eta, \chi)q & \text{for } v = 2^{-1}u, \ h \neq \text{Tr}_{q/p}(w^{-1}v^2), \ \eta(w) = -1.
\end{cases}$$

2) When $m$ is odd, we deduce that

$$\Omega = \begin{cases} 
0 & \text{for } v \neq 2^{-1}u \\
G(\eta, \chi)q\eta(w) \sum_{z \in \text{GF}(p)^*} \chi'((h - \text{Tr}_{q/p}(w^{-1}v^2))z)\eta'(z) & \text{for } v = 2^{-1}u
\end{cases}$$

$$= \begin{cases} 
0 & \text{for } v \neq 2^{-1}u \\
0 & \text{for } v = 2^{-1}u, \ h = \text{Tr}_{q/p}(w^{-1}v^2) \\
G(\eta, \chi)G(\eta', \chi')q\eta(w)\eta'(h - \text{Tr}_{q/p}(w^{-1}v^2)) & \text{for } v = 2^{-1}u, \ h \neq \text{Tr}_{q/p}(w^{-1}v^2)
\end{cases}$$
\[
\begin{align*}
N(u, v, w, h) &= \begin{cases} 
p^{2m-1} & \text{for } v = 2^{-1}u, \ h = \text{Tr}_{q/p}(w^{-1}v^2), \\
p^m - (p - 1)p^{\frac{m}{2}}(\sqrt{-1})^{\frac{m+1}{2}} & \text{for } v = 2^{-1}u, \ h \neq \text{Tr}_{q/p}(w^{-1}v^2), \\
p^m + p^{\frac{m}{2}}(\sqrt{-1})^{\frac{m-1}{2}} & \text{for } v = 2^{-1}u, \ h = \text{Tr}_{q/p}(w^{-1}v^2), \\
p^m - p^{\frac{m+1}{2}}(\sqrt{-1})^{\frac{m+1}{2}} & \text{for } v = 2^{-1}u, \ h \neq \text{Tr}_{q/p}(w^{-1}v^2), \\
p^m - (p - 1)p^{\frac{m}{2}}(\sqrt{-1})^{\frac{m+1}{2}} & \text{for } v = 2^{-1}u, \ h = \text{Tr}_{q/p}(w^{-1}v^2), \ w \neq 0 \text{ or } v \neq 2^{-1}u, \ w \neq 0 \text{ or } w = 0, \ (u, v) \neq (0, 0), \\
p^m + p^{\frac{m}{2}}(\sqrt{-1})^{\frac{m-1}{2}} & \text{for } v = 2^{-1}u, \ h \neq \text{Tr}_{q/p}(w^{-1}v^2), \ w \neq 0, \ (u, v) \neq (0, 0), \\
p^m - p^{\frac{m+1}{2}}(\sqrt{-1})^{\frac{m+1}{2}} & \text{for } v = 2^{-1}u, \ h \neq \text{Tr}_{q/p}(w^{-1}v^2), \ w \neq 0,
\end{cases}
\end{align*}
\]

When \( w = 0 \) and \( (u, v) \neq (0, 0) \), it is easy to deduce that \( \Omega = 0 \).
From the discussions above and Lemma [3.1], we have

\[
\text{wt}(c(u, v, w, h)) = \left( \text{Tr}_{p^m/p}(g(x, y)) + h \right)_{(x, y) \in \mathbb{GF}(p^m)^2, \text{Tr}_{p^m/p}(w)} \in C_v^{(p)}
\]

is then given by
\[ \begin{align*}
\text{for even } m, \text{ where the frequency of each weight can be easily derived with Lemma 4.8 and the Hamming weight } \\
\text{wt}(c(u, v, w, h))
\end{align*}\]
for odd \( m \), where the frequency of each weight can be easily determined.

Note that the dimension is \( 3m + 1 \) as \( A_0 = 1 \) whether \( m \) is even or odd. Then the desired conclusions follow.

**Example 1:** Let \( \mathcal{V} \) be the elliptic quadric.

1) Let \( m = 2 \) and \( w \) be a generator of \( GF(2^3) \) with \( w^2 + w + 1 = 0 \), and \( a = w^3 \). Then \( \mathcal{C}^{(2)}_{\mathcal{V}} \) has parameters \([17, 7, 6]\) and its dual has parameters \([17, 10, 4]\).

2) Let \( m = 3 \) and \( w \) be a generator of \( GF(2^3) \) with \( w^3 + w + 1 = 0 \), and \( a = w^3 \). Then \( \mathcal{C}^{(2)}_{\mathcal{V}} \) has parameters \([65, 10, 28]\) and its dual has parameters \([65, 55, 4]\).

3) Let \( m = 2 \) and \( w \) be a generator of \( GF(3^2) \) with \( w^2 + 2w + 2 = 0 \), and \( a = w^3 \). Then \( \mathcal{C}^{(3)}_{\mathcal{V}} \) has parameters \([82, 7, 51]\) and its dual has parameters \([82, 75, 4]\).

All of these codes and their duals are optimal according to the tables of best codes known maintained at [http://www.codetables.de](http://www.codetables.de).

At the end of this section, we explain why the subfield codes of ovoid codes are interesting. It is known that the set \( \mathcal{V} \) of (11) is an ovoid if and only if \( x^2 + x + a \) is irreducible over \( GF(q) \). The parameters of the subfield code \( \mathcal{C}^{(p)}_{\mathcal{V}} \) of the code \( \mathcal{C}_{\mathcal{V}} \) were determined for all \( a \). In all cases, the code \( \mathcal{C}^{(p)}_{\mathcal{V}} \) has length \( p^{2m} + 1 \).
and dimension $3m + 1$. However, its minimum distance $d^{(p)}$ and weight distribution vary according to $a$ for odd $p$. Specifically, we have the following for odd $p$.

- If $x^2 + x + a$ is irreducible, then $\mathcal{V}$ is an ovoid and
  \[ d^{(p)} = p^{2m-1}(p - 1) - p^{m-1}. \]

  Further, the dual code $C^{(p)\perp}_\mathcal{V}$ has minimum distance $d^{(p)\perp} = 4$.

- If $x^2 + x + a$ is reducible and $a \neq 1/4$, then $\mathcal{V}$ is not an ovoid and
  \[ d^{(p)} = p^{2m-1}(p - 1) - p^{m-1}(p - 1). \]

  Further, the dual code $C^{(p)\perp}_\mathcal{V}$ has minimum distance $3$ according to our experimental data.

- If $m$ is even and $a = 1/4$, then $x^2 + x + a$ is reducible, $\mathcal{V}$ is not an ovoid and
  \[ d^{(p)} = p^{2m-1}(p - 1) - p^{m-1}(p - 1)p^{m/2}. \]

  Further, the dual code $C^{(p)\perp}_\mathcal{V}$ has minimum distance $3$ according to our experimental data.

- If $m$ is odd and $a = 1/4$, then $x^2 + x + a$ is reducible, $\mathcal{V}$ is not an ovoid and
  \[ d^{(p)} = p^{2m-1}(p - 1) - p^{m-1}p^{(m+1)/2}. \]

  Further, the dual code $C^{(p)\perp}_\mathcal{V}$ has minimum distance $3$ according to our experimental data.

Therefore, both $C^{(p)}_\mathcal{V}$ and $C^{(p)\perp}_\mathcal{V}$ have the best minimum distance when $\mathcal{V}$ is an ovoid. The comparison above shows that the subfield codes of ovoid codes are indeed interesting.

V. SUBFIELD CODES OF THE TITS OVOID CODES

Let $q = 2^{2e+1}$ with $e \geq 1$. Recall that the Tits ovoids are defined by
\[ \mathcal{T} = \{(0, 0, 1, 0)\} \cup \{(x, y, x^\sigma + xy + y^{\sigma+2}, 1) : x, y \in \text{GF}(q)\}, \]
where $\sigma = 2^e + 1$. Denote
\[ t_1(x, y) = x, \quad t_2(x, y) = y, \quad t_3(x, y) = x^\sigma + xy + y^{\sigma+2} \]
and
\[ G_{x,y} = \begin{bmatrix} t_1(x, y) \\ t_2(x, y) \\ t_3(x, y) \\ 1 \end{bmatrix}_{(x,y)\in\text{GF}(q)^2} \]
which is a $4 \times q^2$ matrix over GF$(q)$. The Tits ovoid code $C_\mathcal{T}$ over GF$(q)$ has the generator matrix
\[ G_\mathcal{T} = \begin{bmatrix} G_{x,y} \\ 0 \\ 0 \\ 0 \end{bmatrix}. \]

Our task in this section is to investigate the subfield code $C^{(2)}_\mathcal{T}$ of the Tits ovoid code $C_\mathcal{T}$.

Using the definition of $G_\mathcal{T}$ and Theorem 2.5, we have the following trace representation of $C^{(2)}_\mathcal{T}$:
\[ C^{(2)}_\mathcal{T} = \left\{ \left( (\text{Tr}_{q/2}(ut_1(x, y) + vt_2(x, y) + wt_3(x, y)) + h)_{(x,y)\in\text{GF}(q)^2} : \text{Tr}_{q/2}(w) \right) : u, v, w \in \text{GF}(q) \right\} \]
\[ = \left\{ \left( (\text{Tr}_{q/2}(t(x, y)) + h)_{(x,y)\in\text{GF}(q)^2} : \text{Tr}_{q/2}(w) \right) : u, v, w \in \text{GF}(q) \right\} \]
where $t(x, y) := ut_1(x, y) + vt_2(x, y) + wt_3(x, y) = ux + vy + wx^\sigma + xy + wy^{\sigma+2}$. 

We discuss the value of $\chi$ and the weight distribution in Table VI. Its dual $C_{T}^{(2)}$ has parameters $[2^{4e+2} + 1, 6e + 4]$ and the weight distribution in Table VII. Its dual $C_{T}^{(2)\perp}$ has parameters $[2^{4e+2} + 1, 2^{4e+2} - 6e - 3, 4]$.

**Proof** Let $\chi$ be the canonical additive character of $\text{GF}(q)$. Firstly, assume that $(u, v, w) \neq (0, 0, 0)$. Denote

$$N_0(u, v, w) = \#\{(x, y) \in \text{GF}(q)^2 : \text{Tr}_{q/2}(t(x, y)) = 0\}$$

and

$$N_1(u, v, w) = \#\{(x, y) \in \text{GF}(q)^2 : \text{Tr}_{q/2}(t(x, y)) = 1\}.$$ 

By the orthogonality relation of additive characters, we have

$$2N_0(u, v, w) = \sum_{(x,y)\in \text{GF}(q)^2} \sum_{z\in \text{GF}(2)} (-1)^z \text{Tr}_{q/2}(t(x,y))$$

$$= q^2 + \sum_{(x,y)\in \text{GF}(q)^2} (-1)^{\text{Tr}_{q/2}(t(x,y))}. \quad (9)$$

We discuss the value of $N_0(u, v, w)$ in the following cases.

1) If $w = 0$, we have $t(x,y) = ux + vy$. Since $(u, v) \neq (0, 0)$, we deduce that $N_0(u, v, w) = q^2/2 = 2^{4e+1}$.

2) If $w \neq 0$, we denote

$$\Delta = \sum_{(x,y)\in \text{GF}(q)^2} (-1)^{\text{Tr}_{q/2}(t(x,y))}.$$ 

Then

$$\Delta^2 = \left( \sum_{(x,y)\in \text{GF}(q)^2} (-1)^{\text{Tr}_{q/2}(-t(x,y))} \right) \left( \sum_{(x_1,y_1)\in \text{GF}(q)^2} (-1)^{\text{Tr}_{q/2}(t(x_1,y_1))} \right)$$

$$= \sum_{(x,y)\in \text{GF}(q)^2} \sum_{(x_1,y_1)\in \text{GF}(q)^2} (-1)^{\text{Tr}_{q/2}(t(x,y) - t(x_1,y_1))}$$

$$= \sum_{(x,y)\in \text{GF}(q)^2} \sum_{(A,B)\in \text{GF}(q)^2} (-1)^{\text{Tr}_{q/2}(t(x+A,y+B) - t(x,y))}$$

$$= q^2 - \sum_{(A,B)\in \text{GF}(q)^2\setminus\{(0,0)\}} \sum_{(x,y)\in \text{GF}(q)^2} (-1)^{\text{Tr}_{q/2}(t(x+A,y+B) - t(x,y))}$$

$$= q^2 - \sum_{(A,B)\in \text{GF}(q)^2\setminus\{(0,0)\}} \chi(uA + vB + wAB + wA^{2e+1} + wB^{2e+1} + 2) \times \sum_{y\in \text{GF}(q)} \chi(wB^2y^{2e+1} + wB^{2e+1}y^2 + wAy) \sum_{x\in \text{GF}(q)} \chi(wBx)$$

| Weight | Multiplicity |
|--------|--------------|
| $2^{4e+2}$ | 1 |
| $2^{4e+1}$ | 1 |
| $2^{4e+1} + 2^{2e}$ | $2(2^{4e+2} - 1)$ |
| $2^{4e+1} - 2^{2e}$ | $2(2^{4e+2} - 1)$ |
| $2^{4e+1} + 2^{2e} + 1$ | $2^{6e+2}$ |
| $2^{4e+1} - 2^{2e} + 1$ | $2^{6e+2}$ |
interesting to study the subfield codes of the two-weight codes from
It seems very difficult to settle the parameters of the subfield codes of the ovoid codes presented in [9].

C (only six nonzero weights). However, the subfield code
C
the elliptic quadric and Tits ovoid, the subfield code
C
where the frequency of each weight is easy to derive. The dimension is
Combining the two cases above yields
\[ N_0(u, v, w) = 2^{4e+1} \pm 2^{2e}. \]

where (u, v, w) ≠ (0, 0, 0) and
\[ N_1(u, v, w) = 2^{4e+2} - N_0(u, v, w). \]

For any codeword \( c(u, v, w, h) = \left( (\text{Tr}_{q/2}(t(x, y)) + h)_{(x, y) \in \text{GF}(q)^2}, \text{Tr}_{2^m/2}(w) \right) \in C_T^{(2)}, \) by the discussions above we deduce that
\[
\begin{align*}
\text{wt}(c(u, v, w, h)) &= \begin{cases} 
0 & \text{for } (u, v, w, h) = (0, 0, 0, 0) \\
2^{2e+2} & \text{for } (u, v, w, h) = (0, 0, 0, 1) \\
N_1(u, v, w) & \text{for } w = h = 0, (u, v) \neq (0, 0) \\
N_0(u, v, w) & \text{for } w = 0, h = 1, (u, v) \neq (0, 0) \\
N_1(u, v, w) & \text{for } h = 0, w \neq 0, \text{Tr}_{q/2}(w) = 0, (u, v) \in \text{GF}(q)^2 \\
N_0(u, v, w) & \text{for } h = 1, w \neq 0, \text{Tr}_{q/2}(w) = 0, (u, v) \in \text{GF}(q)^2 \\

\end{cases}
\end{align*}
\]

where the frequency of each weight is easy to derive. The dimension is 3m + 1 as A_0 = 1.

The parameters of its dual follow from Theorem 1.1 and the sphere-packing bound.

VI. CONCLUDING REMARKS

Example 1 demonstrates that the subfield code \( C^{(2)}_{\mathcal{O}} \) of some ovoid code \( C_{\mathcal{O}} \) is optimal. When \( \mathcal{O} \) is an elliptic quadric or the Tits ovoid, the dual code \( C^{(2)}_{\mathcal{O}} \) is distance-optimal according to the sphere-packing bound.

Let \( q = 2^m \). Note that every ovoid code \( C \) over \( \text{GF}(q) \) must have parameters \([q^2 + 1, 4, q^2 - q] \) and the weight enumerator
\[
1 + (q^2 - q)(q^2 + 1)z^{q^2 - q} + (q - 1)(q^2 + 1)z^{q^2}.
\]

However, the subfield code \( C^{(2)} \) may have different parameters and weight distributions. In the case of the elliptic quadric and Tits ovoid, the subfield code \( C^{(2)} \) has the same parameters and weight distribution (only six nonzero weights). However, the subfield code \( C^{(2)} \) of another family of ovoid codes documented in [9] has \( 2^m \) nonzero weights and very different parameters according to our Magma experimental data. It seems very difficult to settle the parameters of the subfield codes of the ovoid codes presented in [9].

Finally, we point out that \( m \)-ovoids are related to ovoids and give two-weight codes [11]. It would be interesting to study the subfield codes of the two-weight codes from \( m \)-ovoids.
