Abstract
This report describes the methods and results of a system developed for the GREC Named Entity Recognition and GREC Named Entity Regeneration Challenges 2010. We explain our process of automatically annotating surface text, as well as how we use this output to select improved referring expressions for named entities.

1 Introduction
Generation of References in Context (GREC) is a set of shared task challenges in NLG involving a corpus of introductory sentences from Wikipedia articles. The Named Entity Recognition (GREC-NER) task requires participants to recognize all mentions of people in a document and indicate which mentions corefer. In the Named Entity Regeneration (GREC-Full) task, submitted systems attempt to improve the clarity and fluency of a text by generating improved referring expressions (REs) for all references to people. Participants are encouraged to use the output from GREC-NER as input for the GREC-Full task. To provide ample opportunities for improvement, a certain portion of REs in the corpus have been replaced by more-specific named references. Ideally, the GREC-Full output will be more fluent and have greater referential clarity than the GREC-NER input.

2 Method
The first step in our process to complete the GREC-NER task is to prepare the corpus for input into the parser by stripping all XML tags and segmenting the text into sentences. This is accomplished with a simple script based on common abbreviations and sentence-final punctuation.

Next, the files are run through the Stanford Parser (The Stanford Natural Language Processing Group, 2010), providing a typed dependency representation of the input text from which we extract the syntactic functions (SYNFUNC) of, and relationships between, words in the sentence.

The unmarked segmented text is also used as input for the Stanford Named Entity Recognizer (The Stanford Natural Language Processing Group, 2009). We eliminate named entity tags for locations and organizations, leaving only person entities behind. We find the pronouns and common nouns (e.g. “grandmother”) referring to person entities that the NER tool does not tag. We also identify the REG08-Type and case for each RE. Entities found by the NER tool are marked as names, and the additional REs we identified are marked as either pronouns or common nouns. Case values are determined by analyzing the assigned type and any type dependency representation (provided by the parser) involving the entity. At this stage we also note the gender of each pronoun and common noun, the plurality of each reference, and begin to deal with embedded entities.

The next step identifies which tagged mentions corefer. We implemented a coreference resolution tool using a shallow rule-based approach inspired by Lappin and Leass (1994) and Bontcheva et al. (2002). Each mention is compared to all previously-seen entities on the basis of case, gender, SYNFUNC, plurality, and type. Each entity is then evaluated in order of appearance and compared to all previous entities starting with the most recent and working back to the first in the text. We apply rules to each of these pairs based on the REG08-Type attribute of the current entity. Names and common nouns are analyzed using string and word token matching. We collected extensive, cross-cultural lists of male and female first names to help identify the gender of named entities, which we use together with SYNFUNC values for pronoun resolution. Separate rules govern gender-neutral pronouns such as “who.” By the end of this stage, we have all of the resources
necessary to complete the GREC-NER task.

As a post-processing step, we remove all extra (non-GREC) tags used in previous steps, re-order the remaining attributes in the proper sequence, add the list of REs (ALT-REFEX), and write the final output following the GREC format. At this point, the GREC-NER task is concluded and its output is used as input for the GREC-Full task.

To improve the fluency and clarity of the text by regenerating the referring expressions, we rely on the system we developed for the GREC Named Entity Challenge 2010 (NEG), a refined version of our 2009 submission (Greenbacker and McCoy, 2009a). This system trains decision trees on a psycholinguistically-inspired feature set (described by Greenbacker and McCoy (2009b)) extracted from a training corpus. It predicts the most appropriate reference type and case for the given context, and selects the best match from the list of available REs. For the GREC-Full task, however, instead of using the files annotated by the GREC organizers as input, we use the files we annotated automatically in the GREC-NER task. By keeping the GREC-NER output in the GREC format, our NEG system was able to successfully run unmodified and generate our output for GREC-Full.

3 Results

Scores calculated by the GREC self-evaluation tools are provided in Table 1 for GREC-NER and in Table 2 for GREC-Full.

| Corpus     | MUC-6 | CEAF | B-CUBED |
|------------|-------|------|---------|
|            | F     | prec. | recall  | F     | prec. | recall  | F     | prec. | recall  |
| Entire Set | 71.984 | 69.657 | 74.471  | 68.893 | 68.893 | 68.893  | 72.882 | 74.309 | 71.509  |
| Chefs      | 71.094 | 65.942 | 77.119  | 65.722 | 65.722 | 65.722  | 71.245 | 69.352 | 73.244  |
| Composers  | 68.866 | 66.800 | 71.064  | 68.672 | 68.672 | 68.672  | 71.929 | 73.490 | 70.433  |
| Inventors  | 76.170 | 77.155 | 75.210  | 72.650 | 72.650 | 72.650  | 75.443 | 80.721 | 70.812  |

Table 1: Self-evaluation scores for GREC-NER.

4 Conclusions

Until we compare our results with others teams or an oracle, it is difficult to gauge our performance. However, at this first iteration of these tasks, we’re pleased just to have end-to-end RE regeneration working to completion with meaningful output.

5 Future Work

Future improvements to our coreference resolution approach involve analyzing adjacent text, utilizing more of the parser output, and applying machine learning to our GREC-NER methods.
