DEFORMATIONS OF ALGEBRAIC SCHEMES VIA
REEDY-PALAMODOV COFIBRANT RESOLUTIONS

MARCO MANETTI AND FRANCESCO MEAZZINI

Abstract. Let $X$ be a Noetherian separated and finite dimensional scheme over a field $K$ of characteristic zero. The goal of this paper is to study deformations of $X$ over a differential graded local Artin $K$-algebra by using local Tate-Quillen resolutions, i.e., the algebraic analog of the Palamodov’s resolvent of a complex space. The above goal is achieved by describing the DG-Lie algebra controlling deformation theory of a diagram of differential graded commutative algebras, indexed by a direct Reedy category.

1. Introduction

This paper concerns the use of basic model category theory in the study of deformations of algebraic schemes and morphisms between them, with the aim of being accessible to a wide community, especially to everyone having a classical background in algebraic geometry and deformation theory. For this reason the homotopic and simplicial background is reduced at minimum.

Let $X$ be a Noetherian separated and finite dimensional scheme over a field $K$ of characteristic zero; we study deformations of $X$ over a differential graded local Artin $K$-algebra by using local Tate-Quillen resolutions, i.e., the algebraic analog of the Palamodov’s resolvent of a complex space.

It is well known (see e.g. [26]) that if $X = \text{Spec}(S)$ is affine, then the deformations of $X$ are the same as the deformations of $S$ in the category of commutative algebras. The latter

2010 Mathematics Subject Classification. 18G55,14D15,16W50.

Key words and phrases. Model categories, Deformation theory, Differential graded algebras, Algebraic schemes, Cotangent complex.
are studied by using a Tate-Quillen resolution $R \to S$, and are controlled by the DG-Lie algebra $\text{Der}_R^*(R, R)$ via Maurer-Cartan equation modulus gauge action.

For general schemes, fixing an affine open cover $\{U_i\}_{i \in I}$, the geometry of $X$ is encoded in the diagram

$$S_\cdot : N \to K\text{-algebras}, \quad \alpha \mapsto S_\alpha = \Gamma(U_\alpha, O_X)$$

where $N$ denotes the nerve of the cover; the deformation theory of $X$ is equivalent to the one of $S_\cdot$.

Since Tate-Quillen resolutions are cofibrant objects in the model category $\text{CDGA}_{\leq 0}^K$ of commutative differential (non-positively) graded algebras, it is natural to consider $S_\cdot$ as an element of the category $\text{Fun}(N, \text{CDGA}_{\leq 0}^K)$ of functors $N \to \text{CDGA}_{\leq 0}^K$:

$$(1.1) \quad S_\cdot : N \to \text{CDGA}_{\leq 0}^K, \quad \alpha \mapsto S_\alpha = \Gamma(U_\alpha, O_X)$$

where each $S_\alpha$ is considered as a DG-algebra concentrated in degree 0.

Since $N$ is a (direct) Reedy category then $\text{Fun}(N, \text{CDGA}_{\leq 0}^K)$ is endowed with the Reedy model structure (see Section 3) that is strong left proper (Proposition 3.1), in the sense of [18], briefly recalled here in Definition 2.1. According to the results of [18] there exists a good deformation theory in strong left proper model categories that, among the other properties, is homotopy invariant: in our particular case the deformation theory of any diagram $R_\cdot$ gives a “deformation” functor

$$\text{Def}_{R_\cdot} : \text{DGArt}_{\leq 0}^K \to \text{Set},$$

and for any diagram $P_\cdot$ weak equivalent to $R_\cdot$ we have an isomorphism of functors $\text{Def}_{P_\cdot} \simeq \text{Def}_{R_\cdot}$.

It is easy to prove (Lemma 5.2) that the restriction of $\text{Def}_{S_\cdot}$ to the subcategory of local Artin algebras concentrated in degree 0 is the same as the classical deformation functor of $X$. Therefore the above facts provide a natural way to define deformations of $X$ over general DG-Artin local ring in non-positive degrees; moreover we can replace the diagram $S_\cdot$ with any weak equivalent Reedy cofibrant diagram. It is worth to notice that the algebraic analog of the Palamodov’s resolvent [21, 22] is in fact a special case of Reedy cofibrant replacement.

Finally, for any Reedy cofibrant diagram $R_\cdot$, we shall be able to prove (Lemma 5.3 and Theorem 5.5) that the functor $\text{Def}_{R_\cdot}$ is controlled by the DG-Lie algebra of derivations of $R_\cdot$.

The proposed proof strongly relies on the results of [18], where deformations of affine schemes were considered. More precisely, we show that the ideas developed in [18] in order to understand the deformation theory of an affine (differential graded) scheme can be easily adapted to the non-affine case. Philosophically, we can say that the approach to deformation theory via model categories presented in this paper and in [18], gives not only similar statements in the affine and non-affine case, but also the same underlying ideas and strategies in the proofs.

The same approach leads to the description of the cotangent complex as a certain homotopy class of $S_\cdot$-modules, namely the module of Kähler differentials of a cofibrant replacement (see Section 7). This description relies on the results of [19], where it is proved that the homotopy category of $S_\cdot$-modules is equivalent to the unbounded derived category of quasi-coherent sheaves on $X$.

As also suggested by the referee, it would be interesting, instead of just looking at functors of homotopy classes, to consider simplicial functors as in [9] with moduli interpretations as infinity groupoids as in the Derived Algebraic Geometry literature (Lurie, Pridham, Toën, Vezzosi etc.); the results of this paper easily extend from schemes to derived schemes. However, in view of the general philosophy underlying this paper, we preferred to consider...
this possible extension, possibly after the simplicial analogous of the general formal theory developed in [18].

2. DEFORMATIONS OF MORPHISMS IN STRONG LEFT PROPER MODEL CATEGORIES

The goal of this section is to fix notation and to review some results of [18].

Let $M$ be a fixed model category. For every object $A \in M$ the symbols $A \downarrow M$ and $M_A$ both denote the undercategory of maps $A \to B$, $B \in M$. There is a natural model structure on $M_A$ under which a map is a cofibration, fibration, or weak equivalence if and only if its image in $M$ under the forgetful functor is, respectively, a cofibration, fibration, or weak equivalence. Every morphism $A \to B$ induces a push-out functor $\Pi_A B : M_A \to M_B$ which preserves cofibrations and trivial cofibrations.

**Definition 2.1** (Definitions 2.9 and 2.13 of [18]). A morphism $A \to B$ in a model category $M$ is called flat if the push-out functor $\Pi_A B : M_A \to M_B$ preserves pull-back squares of trivial fibrations. The model category $M$ is said to be strong left proper if every cofibration is flat.

Thus, in a strong left proper model category, the push-out along a cofibration preserves trivial cofibrations and trivial fibrations; hence preserves weak equivalences, i.e. the model category is left proper. Conversely, a left proper model category may not be strong: for instance, the category of topological spaces endowed with the usual model structure is left proper but not strong left proper.

We refer to [18] for a deeper discussion about flat morphisms and for the proof that the class of flat morphisms is closed under composition, push-outs and retracts. An object $X$ in $M$ is called flat if the morphism from the initial object to $X$ is flat; clearly a morphism $A \to M$ is flat as a morphism in $M$ if and only if it is flat as an object in the undercategory $A \downarrow M$.

According to [18, Cor. 3.4] an example of strong left proper model category is $\text{CDGA}_{K}^{\leq 0}$, the category of differential graded commutative algebras over a field $K$ of characteristic 0 concentrated in non-positive degrees, equipped with the projective model structure ([2], [6, V.3]): weak equivalences are the quasi-isomorphisms, cofibrations are the retracts of semifree extensions and fibrations are the surjections in strictly negative degrees.

It is easy to prove that in a left proper model category, weak equivalences between flat objects are preserved under arbitrary push-outs [18, 2.5+2.11]. The converse is generally false and this motivates the following definition.

**Definition 2.2** (Definition 4.2 of [18]). Let $M$ be a left proper model category. A morphism $A \to K$ is said to be a thickening if for every commutative diagram

\[
\begin{array}{c}
A \xrightarrow{g} E \\
\downarrow f \\
D
\end{array}
\]

such that $f, g$ are flat and $h \Pi \text{Id}_K : E \Pi_A K \to D \Pi_A K$ is a weak equivalence (respectively: an isomorphism), then also $h$ is a weak equivalence (respectively: an isomorphism).

For instance, in the model category $\text{CDGA}_{K}^{\leq 0}$ every surjective morphism with nilpotent kernel is a thickening [18, Prop. 3.5]: the name thickening is clearly motivated by the analogous notion for algebraic schemes [4, 8.1.3].
**Definition 2.3.** Let $K \xrightarrow{f} X$ be a morphism in a left-proper model category $\mathcal{M}$, with $X$ a fibrant object. A deformation of $f$ over a thickening $A \xrightarrow{p} K$ is a commutative diagram

$$
\begin{array}{ccc}
A & \xrightarrow{f_A} & X_A \\
p & & \downarrow \\
K & \xrightarrow{f} & X
\end{array}
$$

such that $f_A$ is flat and the induced map $X_A \amalg A K \to X$ is a weak equivalence. A direct equivalence is given by a commutative diagram

$$
\begin{array}{ccc}
A & \xrightarrow{f_A} & X_A \\
g_A & \searrow & \swarrow h \\
Y_A & \xrightarrow{\beta} & X
\end{array}
$$

where $h$ is a weak equivalence. Two deformations are equivalent if they are so under the equivalence relation generated by direct equivalences.

We denote either by $\text{Def}_f(A \xrightarrow{p} K)$ or, with a little abuse of notation, by $\text{Def}_f(A)$ the quotient class of deformations of $f$ up to equivalence. Given any diagram $A \xrightarrow{g} B \xrightarrow{p} K$ with $p, ph$ thickening, then the push-out along $h$ gives a natural map $h: \text{Def}_f(A \xrightarrow{ph} K) \to \text{Def}_f(B \xrightarrow{p} K)$: every diagram

$$
\begin{array}{ccc}
A & \xrightarrow{f_A} & X_A \\
p \hspace{1cm} ph & & \downarrow \\
K & \xrightarrow{f} & X
\end{array}
$$

as in Definition 2.3 is mapped into the diagram

$$
\begin{array}{ccc}
B & \xrightarrow{h \cdot (f_A)} & B \amalg A X_A \\
p & & \downarrow \\
K & \xrightarrow{f} & X
\end{array}
$$

In strong left proper model categories it is possible to describe the class of deformations exclusively in terms of cofibrations.

**Proposition 2.4** (Lemma 4.4 and Prop. 4.6 of [18]). Let $K \xrightarrow{f} X$ be a morphism in a strong left proper model category $\mathcal{M}$, with $X$ a fibrant object. Then every deformation of $f$ over a thickening $A \xrightarrow{p} K$ is represented by a commutative diagram

$$
\begin{array}{ccc}
A & \xrightarrow{f_A} & X_A \\
p & & \downarrow \alpha \\
K & \xrightarrow{f} & X
\end{array}
$$

such that $f_A$ is a cofibration and the induced map $X_A \amalg A K \to X$ is a weak equivalence.

The diagrams (2.2) and

$$
\begin{array}{ccc}
A & \xrightarrow{g_A} & Y_A \\
p & & \downarrow \beta \\
K & \xrightarrow{f} & X
\end{array}
$$

are equivalent.
with $g_A$ a cofibration, represent the same equivalence class of deformations of $f$ if and only if there exists a commutative diagram

\[
\begin{array}{ccc}
A & \xrightarrow{g_A} & Y_A \\
\downarrow & & \downarrow \\
X_A & \xrightarrow{f_A} & Z_A \\
\downarrow & & \downarrow \\
X & \xrightarrow{\alpha} & Y \\
\end{array}
\]

(2.4)

with the horizontal arrows trivial cofibrations.

The assumption that $p$ is a thickening is essential for the validity of the following theorem.

**Theorem 2.5** (Homotopy invariance of deformations: Thm. 5.3 of [18]). Let $K \xrightarrow{\tau} X \xrightarrow{\tau} Y$ be morphisms in a strong left proper model category $M$. If $\tau$ is a weak equivalence between fibrant objects, then for every thickening $A \rightarrow K$, the natural map

\[
\text{Def}_f(A) \rightarrow \text{Def}_{\tau f}(A), \quad (A \rightarrow X_A \rightarrow X) \mapsto (A \rightarrow X_A \rightarrow X \xrightarrow{\tau} Y),
\]

is bijective.

Theorem 2.5 implies that it is properly defined the deformation theory of any morphism $f: K \rightarrow Y$ by setting $\text{Def}_f = \text{Def}_{\tau f}$, where $\tau: Y \rightarrow X$ is any weak equivalence into a fibrant object $X$. At the same time, Theorem 2.5 implies that deformation theory (along a thickening) is invariant under fibrant-cofibrant replacements of $f$ in the undercategory $M_K$: for every diagram

\[
\begin{array}{ccc}
K & \xrightarrow{i} & R \\
\downarrow^f & & \downarrow^\beta \\
Y & \xrightarrow{\alpha} & X \\
\end{array}
\]

with $X$ fibrant, $i$ cofibration, $\beta$ fibration and $\alpha, \beta$ weak equivalences, the morphisms $f$ and $i$ have the same deformation theory.

### 3. Diagrams over direct Reedy categories

Let $C$ be a (non empty) direct Reedy category. This means that $C$ is a small category and there exists a degree function $\text{Ob}(C) \rightarrow \mathbb{N}$ such that every non-identity morphism raises degree. In particular, every object $a$ has only the identity as a morphism $a \rightarrow a$.

Examples of direct Reedy categories are:

1. the category $\Delta$ of finite ordinals with injective strictly monotone maps.
2. the category associated to a Reedy poset: by definition a Reedy poset is a partially ordered set $I$ such that there exists a strictly monotone map $\deg: I \rightarrow \mathbb{N}$, i.e. $\deg(\alpha) < \deg(\beta)$ whenever $\alpha < \beta$.
3. every finite product of direct Reedy categories is a direct Reedy category, equipped with the degree function $\deg(a_1, \ldots, a_n) = \sum \deg(a_i)$.

From now on we shall denote by $C$ a fixed direct Reedy category. As usual we shall denote by $\text{Map}(C)$ the category of maps in $C$: objects are the morphisms in $C$, morphisms are the commutative squares. We are mainly interested in the following full subcategories of $\text{Map}(C)$:

1. for every $a \in C$ denote by $[C, a]$ the full subcategory of $\text{Map}(C)$ whose objects are the morphisms $b \rightarrow a$. This is naturally isomorphic to the overcategory $C \downarrow a$. 
for every $a \in C$ denote by $[C, a]$ the full subcategory of $\text{Map}(C)$ whose objects are the non-identity morphisms $b \rightarrow a$. This is naturally isomorphic to the latching category $0(C \downarrow a)$ defined in [11].

Notice that both $[C, a]$ and $(C, a)$ are direct Reedy categories, with degree function $\deg(b \rightarrow a) = \deg(b)$.

Let $M$ be a fixed model category. For every diagram $X: C \rightarrow M$ and every $a \in C$ we may consider the diagram

$L_a X: \xymatrix{ [C, a] \ar[r] & M, & (b \rightarrow a) \ar[r] & X_b }$.

The latching object of $X$ at $a$ is defined as the colimit of the diagram $L_a X$:

$L_a X = \text{colim}_{[C, a]} L_a X$,

and the latching map of $X$ at $a$ is the natural map induced by the natural maps $(L_a X)_{b \rightarrow a} = X_b \rightarrow X_a$.

The Reedy model structure on the category $M^C$ of diagrams $X: C \rightarrow M$, also denoted by $\text{Fun}(C, M)$, is defined as follows:

1. a morphism $X \rightarrow Y$ is a weak-equivalence (respectively, fibration) if for every $a \in C$ the morphism $X_a \rightarrow Y_a$ is a weak equivalence (respectively, fibration).

2. a morphism $X \rightarrow Y$ is a cofibration if for every $a \in C$ the natural morphism

$X_a \amalg_{L_a X} L_a Y \rightarrow Y_a$

is a cofibration.

It is useful to recall that if $X \rightarrow Y$ is a Reedy cofibration in $M^C$, then $X_a \rightarrow Y_a$ and $L_a X \rightarrow L_a Y$ are cofibrations in $M$ for every $a \in C$, [11, Prop. 15.3.11]. If $M$ is left proper, then also $M^C$ is left proper, [11, Thm. 15.3.4].

It is important to point out that Reedy model structures commute with undercategories and overcategories in the following sense: denoting by $\Delta: M \rightarrow M^C$ the diagonal functor, for any object $A \in M$ there exist canonical isomorphisms of model categories

$\Delta A \downarrow M^C = (A \downarrow M)^C$, $M^C \downarrow \Delta A = (M \downarrow A)^C$.

This is completely trivial since the above natural isomorphisms of categories preserve weak equivalences and fibrations.

Since our goal is to make deformation theory in $M^C$ we need to characterise the flat morphisms.

**Proposition 3.1.** In the above setup, a morphism $X \rightarrow Y$ in $M^C$ is flat if $X_a \rightarrow Y_a$ is flat in $M$ for every $a \in C$. If $M$ is strong left proper, then also $M^C$ is strong left proper.

**Proof.** Let $X \rightarrow Y$ be a morphism in $M^C$, since push-outs and pull-backs are made object-wise, and trivial fibrations are detected object-wise, it is clear that if every $X_a \rightarrow Y_a$ is flat, then also $X \rightarrow Y$ is flat.

If $M$ is strong left proper and $X \rightarrow Y$ is a cofibration in $M^C$, we have seen that $X_a \rightarrow Y_a$ is a cofibration for every $a \in C$, hence $X_a \rightarrow Y_a$ is flat for every $a$ and therefore also $X \rightarrow Y$ is flat. 

**Lemma 3.2.** In the above setup, a cone $\Delta A \rightarrow Y$ in $M^C$ is flat if and only if $A \rightarrow Y_a$ is flat for every $a \in C$.

**Proof.** One implication is proved in Proposition 3.1. The converse is an easy consequence of the fact that the diagonal functor $\Delta: M \rightarrow M^C$ preserves pull-back squares of trivial fibrations and pull-back squares in $M^C$ are detected object-wise.
Corollary 3.3. In the above setup, a morphism \( A \to K \) in \( \mathcal{M} \) is a thickening if and only if \( \Delta A \to \Delta K \) is a thickening in \( \mathcal{M}^C \).

Proof. Since the diagonal functor \( \Delta \) commutes with push-outs, its application to the diagram (2.1) immediately implies that if \( \Delta A \to \Delta K \) is a thickening then \( A \to K \) is a thickening.

If \( \Delta A \to Y \) is flat, then for every \( a \in \mathcal{C} \) we have
\[
(\Delta K \amalg \Delta A \amalg Y)_a = K \amalg A \amalg Y_a
\]
and the morphism \( A \to Y_a \) is flat by Lemma 3.2: this implies that if \( A \to K \) is a thickening then \( \Delta A \to \Delta K \) is a thickening. \( \square \)

Thus, according to Proposition 3.1 and the results of Section 2, there exists a good deformation theory of diagrams in a strong left proper model category \( \mathcal{M} \) over a direct Reedy index category \( \mathcal{C} \).

If we restrict to diagonal thickenings in \( \mathcal{M}^C \), i.e., to thickenings of the form \( \Delta A \to \Delta K \) with \( A \to K \) a thickening in \( \mathcal{M} \), by Corollary 3.3 we obtain the following equivalent description of deformations.

Definition 3.4. Given a thickening \( p: A \to K \) in \( \mathcal{M} \) and a fibrant diagram \( X \in (\mathcal{M}_K)^C = (K \downarrow \mathcal{M})^C = \Delta K \downarrow \mathcal{M}^C \), a deformation of \( X \) along \( p \) is a commutative square
\[
\begin{array}{ccc}
\Delta A & \longrightarrow & X' \\
\downarrow^f & & \downarrow \\
\Delta K & \longrightarrow & X
\end{array}
\]
such for every \( a \in \mathcal{C} \) the map \( f_a: A \to X'_a \) is flat and the map \( X_a \amalg A \amalg K \to X_a \) is a weak equivalence.

The main goal of this paper is to study deformations of a diagram with values in the strong left proper model category \( \text{CDGA}^{\leq 0}_K \) over an element in the full subcategory \( \text{DGArt}^{\leq 0}_K \) of local Artinian DG-algebras with residue field \( K \). This make sense since, according to [18, Prop. 3.5] every surjective morphism in \( \text{DGArt}^{\leq 0}_K \) is a thickening in the model category \( \text{CDGA}^{\leq 0}_K \), and every diagram in \( \text{Fun}(\mathcal{C}, \text{CDGA}^{\leq 0}_K) \) is Reedy fibrant: for a direct Reedy category \( \mathcal{C} \), a deformation of a diagram \( X \in \text{Fun}(\mathcal{C}, \text{CDGA}^{\leq 0}_K) \) over \( A \in \text{DGArt}^{\leq 0}_K \) is a flat diagram \( X_A \in \text{Fun}(\mathcal{C}, \text{CDGA}^{\leq 0}_K) \) equipped with a weak equivalence \( X_A \amalg A \amalg K \to X \), where \( X_A \amalg A \amalg K \) denotes the diagram defined by \( (X_A \amalg A \amalg K)_a = X_{A,a} \amalg A \amalg K \) for every \( a \in \mathcal{C} \).

4. Lifting of trivial idempotents

By definition, a trivial idempotent in a model category is an endomorphism \( e: X \to X \) which is a weak equivalence satisfying \( e^2 = e \). The next goal is to prove a lifting result for trivial idempotents that will be essential for the computation of the DG-Lie algebra controlling deformations of diagrams of algebras over direct Reedy categories. We first need a preliminary lemma.

Lemma 4.1. Let \( \mathcal{M} \) be a left proper model category and \( \mathcal{C} \) a direct Reedy category. Assume it is given a Reedy cofibration \( i: P \to R \), an element \( a \in \mathcal{C} \) and a morphism of diagrams \( e: \mathcal{L}_a R \to \mathcal{L}_a R \) that is a trivial idempotent satisfying \( ei = i \). Then
\[
e: P_a \amalg L_a P L_a R \to P_a \amalg L_a P L_a R,
\]
is a trivial idempotent in the model category $\mathcal{M}$.

Proof. For every diagram $X$ in $\mathcal{M}^{C}$ and every $a \in C$ we may write $L_{a}X = \text{colim} \mathcal{L}_{a}X$, where

$$\mathcal{L}_{a}X : [C, a] \to \mathcal{M}, \quad (\mathcal{L}_{a}X)_{b\to a} = X_{b},$$

For every morphism $f : b \to a$ in $[C, a]$ there exists a natural bijection

$$[C, b] \xrightarrow{\cong} [(C, a), f], \quad c \xrightarrow{g} b \mapsto \begin{array}{ccc} c & \xrightarrow{g} & b \\ \downarrow f & & \downarrow f \\ a & & a \end{array},$$

and this implies that the latching functor

$$\mathcal{L}_{a} : \mathcal{M}^{C} \to \mathcal{M}^{[C, a]}, \quad X \mapsto \mathcal{L}_{a}X,$$

preserves fibrations, cofibrations and weak equivalences.

In particular $\mathcal{L}_{a}P \to \mathcal{L}_{a}R$ is a Reedy cofibration, and taking its push-out along the natural map $\mathcal{L}_{a}P \to \Delta_{a}P$ we get a Reedy cofibration

$$\Delta_{a}P \to \Delta_{a}P \amalg_{\mathcal{L}_{a}P} \mathcal{L}_{a}R$$

in $\mathcal{M}^{[C, a]}$: equivalently the diagram

$$Q : [C, a] \to \mathcal{M}_{P_{a}}, \quad Q_{b\to a} = P_{a} \amalg_{P_{a}} R_{b},$$

is Reedy cofibrant in $\mathcal{M}_{P_{a}}^{[C, a]}$.

For every $b \to a$, since $P_{a} \amalg_{P_{b}} R_{b}$ is a cofibration and $\mathcal{M}$ is left proper, by gluing lemma the idempotent $e : P_{a} \amalg_{P_{b}} R_{b} \to P_{a} \amalg_{P_{b}} R_{b}$ is a weak equivalence. Since $[C, a]$ has fibrant constants, the colimit functor $\text{colim} : \mathcal{M}_{P_{a}}^{[C, a]} \to \mathcal{M}_{P_{a}}$ preserves weak equivalences between cofibrant objects and the conclusion follows from the natural isomorphism

$$\text{colim} Q = P_{a} \amalg_{L_{a}P} L_{a}R$$

that holds since colimits commute with push-outs. \qed

We are now ready to use Lemma 4.1 together [18, Theorem 6.12] in order to prove the main result of this section. For every morphism $A \to B$ in $\text{CDGA}_{A}^{\leq 0}$ and every direct Reedy category $C$ we shall denote by $- \otimes_{A} B : \text{Fun}(C, \text{CDGA}_{A}^{\leq 0}) \to \text{Fun}(C, \text{CDGA}_{B}^{\leq 0})$ the natural functor induced by composition with the usual push-out map $- \otimes_{A} B : \text{CDGA}_{A}^{\leq 0} \to \text{CDGA}_{B}^{\leq 0}$.

**Theorem 4.2** (Lifting of trivial idempotents). Let $C$ be a direct Reedy category, $A \to B$ a surjective morphism in $\text{DGArt}_{K}^{\leq 0}$ and $i : X \to Y$ a cofibration of flat diagrams in $\text{Fun}(C, \text{CDGA}_{A}^{\leq 0})$.

Then every trivial idempotent $e$ of $Y \otimes_{A} B$, commuting with the cofibration $X \otimes_{A} B \to Y \otimes_{A} B$, lifts to a trivial idempotent $e_{A} : Y \to Y$ such that $e_{A}i = i$.

Proof. Define an ideal of $C$ as a full subcategory $B$ such that if $b \in B$ and $a \to b$ is a morphism in $C$, then also $a \in B$. By induction on the degree of objects in $C$ it is sufficient to prove that if the trivial idempotent $e_{A}$ as in the theorem is defined for the restriction of $Y : C \to \text{CDGA}_{A}^{\leq 0}$ to an ideal $B \subset C$, then $e_{A}$ can be extended to the restriction of $Y$ to the ideal $B \cup \{a\}$, where $a \in C - B$ is any element of minimum degree.

The trivial idempotent of $Y_{|B}$ induces a trivial idempotent on the latching functor $\mathcal{L}_{a}Y$ and then, according to Lemma 4.1, we have a trivial idempotent in $\text{CDGA}_{A}^{\leq 0}$:

$$L_{a}e : X_{a} \otimes_{L_{a}X} L_{a}Y \to X_{a} \otimes_{L_{a}X} L_{a}Y.$$
Since the reduction of \( L_a e \) along \( B \) extends to the trivial idempotent \( e_a \) of \( Y_a \odot_A B \), according to [18, Theorem 6.12] there exists a trivial idempotent \( e_a : Y_a \to Y_a \) lifting \( e_a \) and extending \( L_a e \).

As in [18, Section 6], Theorem 4.2 has a number of important consequences on the lifting of factorisations and the push-out of deformations along trivial cofibrations. We write here only the statements, since the proofs are exactly the same, mutatis mutandis, of the corresponding results of the above mentioned paper. For simplicity, we shall call \((C,FW)\)-factorisation and \((CW,F)\)-factorisation the two functorial factorisations given by model category axioms.

**Corollary 4.3** (cf. [18, Thm. 6.13]). Let \( A \to B \) be a surjection in \( \text{DGArt}_{\mathbb{K}}^{\leq 0} \) and consider a morphism \( f : P \to M \) in \( \text{Fun}(C, \text{CDGA}_{A}^{\leq 0}) \) between flat diagrams. Then every \((C,FW)\)-factorisation of the reduction

\[
\mathcal{F} : \mathcal{T} = P \otimes_A B \to \mathcal{M} = M \otimes_A B
\]

lifts to a \((C,FW)\)-factorisation of \( f \). In other words, for every factorisation \( \mathcal{T} \xrightarrow{\xi} \mathcal{Q} \xrightarrow{\mathcal{F}_{\mathcal{W}}} \mathcal{M} \) of \( \mathcal{F} \) there exists a commutative diagram

\[
\begin{array}{ccc}
P & \xrightarrow{\xi} & Q \xrightarrow{\mathcal{F}_{\mathcal{W}}} M \\
\downarrow & & \downarrow \\
P & \xrightarrow{\xi} & Q \xrightarrow{\mathcal{F}_{\mathcal{W}}} M
\end{array}
\]

in \( \text{Fun}(C, \text{CDGA}_{A}^{\leq 0}) \), where the upper row reduces to the bottom row applying the functor \( - \otimes_A B \) and the vertical morphisms are the natural projections.

**Corollary 4.4** (cf. [18, Thm. 6.15]). Let \( A \to B \) be a surjection in \( \text{DGArt}_{\mathbb{K}}^{\leq 0} \) and consider a morphism \( f : P \to M \) in \( \text{Fun}(C, \text{CDGA}_{A}^{\leq 0}) \) between flat diagrams. Then every \((CW,F)\)-factorisation of the reduction

\[
\mathcal{F} : \mathcal{T} = P \otimes_A B \to \mathcal{M} = M \otimes_A B
\]

lifts to a \((CW,F)\)-factorisation of \( f \). In other words, for every factorisation \( \mathcal{T} \xrightarrow{\xi} \mathcal{Q} \xrightarrow{\mathcal{F}} \mathcal{M} \) of \( \mathcal{F} \) there exists a commutative diagram

\[
\begin{array}{ccc}
P & \xrightarrow{\xi} & Q \xrightarrow{\mathcal{F}} M \\
\downarrow & & \downarrow \\
P & \xrightarrow{\xi} & Q \xrightarrow{\mathcal{F}} M
\end{array}
\]

in \( \text{Fun}(C, \text{CDGA}_{A}^{\leq 0}) \), where the upper row reduces to the bottom row applying the functor \( - \otimes_A B \) and the vertical morphisms are the natural projections.

**Corollary 4.5** (cf. [18, Cor. 6.14]). Let \( A \in \text{DGArt}_{\mathbb{K}}^{\leq 0} \) and consider a morphism \( f : P \to M \) in \( \text{Fun}(C, \text{CDGA}_{A}^{\leq 0}) \) between flat diagrams. Then \( f \) is a Reedy cofibration if and only if its reduction \( \mathcal{F} : P \otimes_A \mathbb{K} \to M \otimes_A \mathbb{K} \) is a Reedy cofibration in \( \text{Fun}(C, \text{CDGA}_{\mathbb{K}}^{\leq 0}) \).

**Corollary 4.6** (cf. [18, Cor. 6.16]). Let \( A \in \text{DGArt}_{\mathbb{K}}^{\leq 0} \) and consider a flat diagram \( P \in \text{Fun}(C, \text{CDGA}_{A}^{\leq 0}) \). For every trivial cofibration \( \mathcal{F} : \mathcal{T} = P \otimes_A \mathbb{K} \to \mathcal{Q} \) in \( \text{CDGA}_{\mathbb{K}}^{\leq 0} \) there exist a flat diagram \( Q \in \text{Fun}(C, \text{CDGA}_{A}^{\leq 0}) \) such that \( Q \otimes_A \mathbb{K} = \mathcal{Q} \) and a trivial cofibration \( f : P \to Q \) lifting \( \mathcal{F} \).
Corollary 4.7 (cf. [18, Cor. 6.17]). Let $A \in \text{DGArt}_{K}^{\leq 0}$ and consider a Reedy cofibrant diagram $Q \in \text{Fun}(C, \text{CDGA}_{A}^{\leq 0})$. For every trivial cofibration $\overline{f}: \overline{P} \to \overline{Q} = Q \otimes_{A} K$ in $\text{Fun}(C, \text{CDGA}_{A}^{\leq 0})$ there exist a flat diagram $P \in \text{Fun}(C, \text{CDGA}_{A}^{\leq 0})$ such that $P \otimes_{A} K = \overline{P}$ and a lifting of $\overline{f}$ to a trivial cofibration $f: P \to Q$.

5. THE DG-LIE ALGEBRA CONTROLLING DEFORMATIONS OF DIAGRAMS OF DG-ALGEBRAS OVER DIRECT REEDY CATEGORIES.

Let $C$ be a fixed direct Reedy category. We have already pointed out at the end of Section 3 that the general deformation theory of morphisms in strong left proper model categories applies to any diagram $X \in \text{Fun}(C, \text{CDGA}_{A}^{\leq 0})$ and to every diagonal thickening of Artin type $\Delta A \to \Delta K$, $A \in \text{DGArt}_{K}^{\leq 0}$. In this case, for every $A \in \text{DGArt}_{K}^{\leq 0}$ the trivial deformation is defined as a deformation equivalent to the push-out along $\Delta K \to \Delta A$: in other words, the trivial deformation of $X$ along $A$ is represented by the diagram of differential graded algebras $a \mapsto X_{a} \otimes_{K} A$.

For simplicity of notation we shall talk of deformations of $X$ over $A$ intending deformations over $\Delta A \to \Delta K$.

It is useful to introduce the notion of strict deformation: a strict deformation of a diagram $X \in \text{Fun}(C, \text{CDGA}_{A}^{\leq 0})$ over $A \in \text{DGArt}_{K}^{\leq 0}$ is the data of a flat diagram $X_{A} \in \text{Fun}(C, \text{CDGA}_{A}^{\leq 0})$ together an isomorphism of diagrams $X_{A} \otimes_{A} K \to X$. The functor $D_{X}$ of strict deformations of $X$ is defined by

$$D_{X}(A) = \frac{\text{strict deformations of } X \text{ over } A}{\text{isomorphisms}}$$

and it is immediate from definitions and Nakayama’s lemma that whenever $X$ and $A$ are concentrated in degree 0, then $D_{X}(A)$ are precisely the “classical” deformations of $X$ over $A$. Notice that the full subcategory of objects in $\text{DGArt}_{K}^{\leq 0}$ concentrated in degree 0 is exactly the usual category $\text{Art}_{K}$ of local Artin $K$-algebras with residue field $K$.

Example 5.1 (Deformations of idempotent morphisms). The following trick transform the problem of deformation of an object equipped with an idempotent endomorphism, into the deformation problem of a diagram over a direct Reedy category.

Denote by $C$ the full subcategory of $\hat{\Delta}$ having as objects the 3 finite ordinals $[0], [1], [2]$. We can visualise $C$ as a quiver with relations:

$$[0] \xleftarrow{\delta_{0}} [1] \xrightarrow{\delta_{2}} [2] \xleftarrow{\delta_{1}} [1], \quad \delta_{0}^{2} = \delta_{1} \delta_{0}, \quad \delta_{0} \delta_{1} = \delta_{2} \delta_{0}, \quad \delta_{1}^{2} = \delta_{2} \delta_{1}.$$  

It is immediate to see that for any category $M$, every diagram $F: C \to M$ such that $F(\delta_{i})$ is an isomorphism whenever $i > 0$, is isomorphic to a diagram of the form:

$$R \xrightarrow{e} R \xleftarrow{id} R, \quad R \in M, \quad e^{2} = e.$$  

If $M$ is the category of (non-graded) commutative $K$-algebras, since isomorphisms are preserved under strict deformations, there exists a natural bijection between strict deformations of the diagram (5.2) and deformations of the pair $(R, e)$. 
As pointed out in [18], the functor of strict deformations is not homotopy invariant and then it is not the right object to consider; however it is very useful in order to relate the functor $\text{Def}_X$ with classical deformations and with solutions of Maurer-Cartan equations.

**Lemma 5.2.** In the above set-up, if $X$ is a diagram of algebras concentrated in degree 0 and $A \in \text{Art}_K$, then the natural map $D_X(A) \to \text{Def}_X(A)$ is bijective.

**Proof.** By Nakayama’s lemma, if $X_A, Y_A$ are two strict deformations of $X$, then $X, Y$ are diagram of $A$-algebras concentrated in degree 0. In particular $X, Y$ are weak equivalent in $\text{Fun}(C, \text{CDGA}_A^{\leq 0})$ if and only if they are isomorphic; this implies that $D_X(A) \to \text{Def}_X(A)$ is injective.

If $X \in \text{Fun}(C, \text{CDGA}_A^{\leq 0})$ is a deformation of $X$, then by the standard criterion of flatness in terms of relations [1, 26] we have that for every $a \in C$ the $A$-algebra $H^0(X_a)$ is flat and the projection $X_a \to H^0(X_a)$ is a quasi-isomorphism. Therefore $H^0(X)$ belongs to $D_X(A)$ and it is equivalent to $X$; this implies that $D_X(A) \to \text{Def}_X(A)$ is surjective. □

**Lemma 5.3.** In the above set-up, if $X \in \text{Fun}(C, \text{CDGA}_A^{\leq 0})$ is Reedy cofibrant and $A \in \text{DGArt}_K^{\leq 0}$, then the natural map $D_X(A) \to \text{Def}_X(A)$ is bijective.

**Proof.** We first note that if $A \to X \xrightarrow{\phi} X$ is a strict deformation of $X$, then $K \to X_A \otimes_A K$ is a Reedy cofibration and then, by Corollary 4.5 also $A \to X$ is a Reedy cofibration.

**Injectivity.** Consider two strict deformations $A \to X_A \xrightarrow{\phi} X$ and $A \to Y_A \xrightarrow{\psi} X$ that are mapped in the same element of $\text{Def}_X$. Notice that $\phi, \psi$ are objectwise surjective and hence fibrations. By Proposition 2.4 there exists a deformation $A \to Z_A \to X$ in $\text{Def}_X(A)$ together with a commutative diagram

\[
\begin{array}{ccc}
X_A & \xrightarrow{i} & Z_A \\
\downarrow{\phi} & & \downarrow{\eta} \\
X & & Y_A \\
\downarrow{\psi} & & \\
X & & \end{array}
\]

such that $\sigma, \iota$ are Reedy trivial cofibrations. In order to prove that $A \to X_A \to X$ is isomorphic to $A \to Y_A \to X$, we use the fact that, since $\sigma$ is a trivial cofibration, the diagram of solid arrows

\[
\begin{array}{ccc}
Y_A & \xrightarrow{id} & Y_A \\
\downarrow{\sigma} & & \downarrow{\psi} \\
Z_A & \xrightarrow{\pi} & X \\
\downarrow{\eta} & & \\
X & & \end{array}
\]

admits a lifting $\pi: Z_A \to Y_A$. Therefore, the diagram

\[
\begin{array}{ccc}
A & \xrightarrow{\pi \circ \iota} & Y_A \\
\downarrow{\phi} & & \downarrow{\psi} \\
X & & \end{array}
\]

commutes, and the reduction $\pi \circ \iota: X_A \otimes_A K \to Y_A \otimes_A K$ is an isomorphism. To conclude observe that $A \to K$ is a thickening and then $\pi \circ \iota$ is an isomorphism too.
Surjectivity. By Proposition 2.4 it is sufficient to prove that every deformation
\[ A \xrightarrow{i} X_A \xrightarrow{\pi} X, \]
with \( i \) a Reedy cofibration is equivalent to a strict deformation. Thus \( X_A \otimes_A \mathbb{K} \xrightarrow{\pi} X \) is a weak equivalence of Reedy cofibrant diagrams and then, by the standard argument used in Ken Brown’s lemma there exists a commutative diagram
\[
\begin{array}{ccc}
X_A \otimes_A \mathbb{K} & \xrightarrow{f} & Y \\
\downarrow \pi & & \downarrow g \\
X & & X
\end{array}
\]
with \( f, g \) trivial cofibrations and \( \sigma \) trivial fibration. By Corollary 4.6 there exists a trivial cofibration \( X_A \to Y_A \) lifting \( X_A \otimes_A \mathbb{K} \xrightarrow{f} Y \). By Corollary 4.7 there exists a flat diagram \( Z_A \in \text{Fun}(\mathcal{C}, \text{CDGA}_A^{\leq 0}) \) and a trivial cofibration \( Z_A \to Y_A \) lifting \( X \xrightarrow{\pi} Y \). Therefore \( A \to Z_A \to X \) is a strict deformation equivalent to \( A \xrightarrow{i} X_A \xrightarrow{\pi} X \).

\[ \square \]

Lemma 5.4. In the above situation, let \( A \in \text{DGArt}_A^{\geq 0} \) and \( \Delta A \xrightarrow{i} X \) a Reedy cofibration in \( \text{Fun}(\mathcal{C}, \text{CDGA}_A^{\leq 0}) \). Denoting by \( X = X \otimes_A \mathbb{K} = X \otimes_{\Delta A} \Delta \mathbb{K} \), we have a commutative diagram of diagrams

\[
\begin{array}{ccc}
\Delta A & \xrightarrow{i} & X \\
\downarrow j & & \downarrow g \\
X \otimes_{\Delta A} \Delta A & \xrightarrow{\tilde{g}} & X
\end{array}
\]

where \( j \) is the natural push-out map and \( g \) is an isomorphism of diagrams of graded algebras.

Proof. Consider the polynomial algebra \( A[\bar{d}^{-1}] \in \text{CDGA}_A^{\leq 0} \), where \( \bar{d}^{-1} \) is a variable of degree \( -1 \) whose differential is \( d(\bar{d}^{-1}) = 1 \). Then the natural inclusion \( \alpha: A \to A[\bar{d}^{-1}] \) is a morphism of DG-algebras, while the natural projection \( \beta: A[\bar{d}^{-1}] \to A \) is a morphism of graded algebras; moreover \( \beta \alpha \) is the identity on \( A \). Since \( X \to X \) is pointwise surjective, the induced morphism \( X \otimes_A A[\bar{d}^{-1}] \to X \otimes_A A[\bar{d}^{-1}] \) is a trivial fibration, we have a commutative diagram

\[
\begin{array}{ccc}
\Delta A & \xrightarrow{i} & X \otimes_A A[\bar{d}^{-1}] \\
\downarrow j & & \downarrow \tilde{g} \\
X \otimes_{\Delta A} \Delta A & \xrightarrow{\tilde{g}} & X \otimes_A A[\bar{d}^{-1}]
\end{array}
\]

and we can take \( g \) as the composition of \( \tilde{g} \) and \( \text{Id} \otimes \beta \). In order to prove that \( g \) is an isomorphism we can forget the differential everywhere and observe that the projection \( A \to \mathbb{K} \) remains a thickening. \[ \square \]

We can rephrase Lemma 5.4 by saying that every strict deformation over \( A \) of a cofibrant diagram \( X \) is obtained by perturbing the differential of the trivial deformation \( X \otimes_{\mathbb{K}} A \). Conversely every diagram \( X \) of \( A \)-algebras obtained perturbing the differential of \( X \otimes_{\mathbb{K}} A \) is pointwise flat by [18, Prop. 7.6] and then \( X \) is a strict deformation of \( X \); (notice that this last point is false if the algebras are not concentrated in non-positive degrees, see [18, Rem. 7.9]).

Recall that for every \( R \in \text{CDGA}_A^{\leq 0} \), the DG-Lie algebra of derivations of \( R \) is denoted by \( \text{Der}_A^{\mathbb{K}}(R, R) = \oplus_{i \in \mathbb{Z}} \text{Der}_A^{\mathbb{K}}(R, R) \), where
\[ \text{Der}_A^{\mathbb{K}}(R, R) = \{ \alpha \in \text{Hom}_A^\mathbb{K}(R, R) \mid \alpha(xy) = \alpha(x)y + (-1)^{|x|} x \alpha(y) \} , \]
the bracket is the graded commutator and the differential is the adjoint operator of the
differential of $R$.

We can extend naturally the above notion to every diagram $R \in \text{Fun}(\mathcal{C}, \text{CDGA}^{\leq 0}_K)$; for
every morphism $f: a \rightarrow b$ in $\mathcal{C}$ we shall denote by $R_f: R_a \rightarrow R_b$ the induced morphism of
differential graded algebras. Then we define
\begin{equation}
\text{Der}^*_L(R, R) \subset \prod_{a \in \mathcal{C}} \text{Der}^*_L(R_a, R_a)
\end{equation}
as the DG-Lie subalgebra of sequences $\{\alpha_a\}_{a \in \mathcal{C}}$ such that for every morphism $f: a \rightarrow b$
we have $R_f \alpha_b = \alpha_a R_f$. Equivalently, an element of $\text{Der}^*_L(R, R)$ is a morphism of diagrams
that is pointwise a derivation.

Any DG-Lie algebra $L$ over the field $\mathbb{K}$ induces a functor
\[\text{Def}_L: \text{DGArt}^{\leq 0}_K \rightarrow \text{Set}\]
defined in the usual way as the quotient of Maurer-Cartan element modulus gauge action
\[\text{Def}_L(A) = \frac{\text{MC}_L(A)}{\text{gauge}} = \left\{ \eta \in (L \otimes_K \mathfrak{m}_A)^{1} \mid \frac{1}{2}[\eta, \eta] = 0 \right\}.\]
Therefore every diagram $R \in \text{Fun}(\mathcal{C}, \text{CDGA}^{\leq 0}_K)$ induces a deformation functor
\[\text{Def}_{\text{Der}^*_L(R, R)}: \text{DGArt}^{\leq 0}_K \rightarrow \text{Set}.\]

In the following result we denote by $\text{MC}_{\text{Der}^*_L(R, R)}(A)$ the set of **Maurer-Cartan elements**, i.e.,
\[\text{MC}_{\text{Der}^*_L(R, R)}(A) = \left\{ \eta \in (\text{Der}^*_L(R, R) \otimes_K \mathfrak{m}_A)^{1} \mid \frac{1}{2}[\eta, \eta] = 0 \right\}.\]

**Theorem 5.5.** Let $\mathcal{C}$ be a direct Reedy category, let $R \in \text{Fun}(\mathcal{C}, \text{CDGA}^{\leq 0}_K)$ be a Reedy
cofibrant diagram and denote by $D_R$ the functor of strict deformations of $R$. Then for
every $A \in \text{DGArt}^{\leq 0}_K$ there exists a natural bijection
\[\text{Def}_{\text{Der}^*_L(R, R)}(A) \rightarrow D_R(A),\]
induced by the map
\[\text{MC}_{\text{Der}^*_L(R, R)}(A) \rightarrow D_R(A), \quad \xi \mapsto (R \otimes_K A, d_R + \xi).\]

**Proof.** We first notice that, according to [18, Prop. 7.7] every diagram of type $(R \otimes_K A, d_R + \xi)$, with $\xi \in \text{MC}_{\text{Der}^*_L(R, R)}(A)$ is flat over $A$ and then it is a strict deformation of $R$, while
by Lemma 5.4 every strict deformation is of this type.

The conclusion follows by observing that, the gauge equivalence corresponds to iso-
morphisms of diagrams of algebras whose reduction to the residue field is the identity. In
fact, given such an isomorphism $\varphi_A: R_A \rightarrow R'_A$ we can write $\varphi_A = \text{id} + \eta_A$ for some
$\eta_A \in (\text{Hom}_K(R, R) \otimes_K \mathfrak{m}_A)^{0}$. Now, since $\mathbb{K}$ has characteristic 0, we can take the logarithm
to obtain $\varphi_A = e^{\theta_A}$ for some $\theta_A \in (\text{Der}^*_L(R, R) \otimes_K \mathfrak{m}_A)^{0}$. \hfill $\square$

**Corollary 5.6.** Let $\mathcal{C}$ be a direct Reedy category, $S \in \text{Fun}(\mathcal{C}, \text{CDGA}^{\leq 0}_K)$ a diagram and
$R \rightarrow S$ a Reedy cofibrant replacement. Then the DG-Lie algebra $\text{Der}^*_L(R, R)$ controls the
deformation functor $\text{Def}_S$.

**Proof.** By Theorem 2.5 and Lemma 5.3 we have $\text{Def}_S \simeq \text{Def}_R \simeq D_R$. The conclusion follows
immediately from Theorem 5.5. \hfill $\square$

**Example 5.7** (Deformations of algebra morphisms). The first application of the above
results concerns deformations of a morphism of DG-algebras $f: B \rightarrow C$. We choose a
cofibrant resolution $p: R \rightarrow B$, followed by a factorisation of $fp$ as a cofibration $i: R \rightarrow S$
and a trivial fibration $q: S \to C$. Then $i: R \to S$ is a Reedy cofibrant resolution of the diagram $f: B \to C$ and the DG-Lie algebra controlling deformations of $f$ is given by

$$L = \{ \alpha \in \text{Der}^*_K(S, S) \mid \alpha i(R) \subset i(R) \}.$$ 

If one is interested to deformations where both $B, C$ remain fixed, i.e., to morphisms of DG-algebras of type $B \otimes A \to C \otimes A$ reducing to $f$ modulo $m_A$ we need to consider the homotopy fibre of the inclusion of DG-Lie algebras $L \to \text{Der}^*_K(R, R) \times \text{Der}^*_K(S, S)$, cf. [14, 17].

6. The Reedy-Palamodov resolvent and deformations of schemes

Let $X$ be a separated scheme over a field $K$ of characteristic 0 and let $\{U_i\}_{i \in I}$ an affine open cover of $X$; actually the separatedness assumption is only needed to ensure that every finite intersection of elements of $\{U_i\}_{i \in I}$ is an affine open subset, therefore this hypothesis could be relaxed by requiring that $X$ is semi-separated and that $\{U_i\}_{i \in I}$ is a semi-separating cover.

The nerve $N$ of the covering is a Reedy poset with the cardinality as degree function. Denoting as usual by $U_{\{i_1, \ldots, i_k\}} = U_{i_1} \cap \cdots \cap U_{i_k}$, since every $U_\alpha$, $\alpha \in N$, is an affine open subset, the geometry of $X$ is completely determined by the diagram of $K$-algebras

$$S: N \to \text{CDGA}_{\leq 0}^K, \quad \alpha \mapsto S_\alpha = \Gamma(U_\alpha, \mathcal{O}_X).$$

Since the trivial algebra 0 is the final object in the category $\text{CDGA}_{\leq 0}^K$ the restriction of $S$ to the nerve is useful but no strictly necessary: the same works if $S$ is defined on the entire family of finite subsets of $I$, with $S_\alpha = 0$ whenever $U_\alpha = \emptyset$.

A deformation of $X$ over a local Artin ring $A \in \text{Art}_K$ can be interpreted as the data of a deformation over $A$ of every open subset $U_i$ together with a deformation of the corresponding descent data. In other words, there exists a natural bijection between isomorphism classes of deformations of the scheme $X$ and isomorphism classes of deformations of the diagram

$$U: N^{\text{op}} \to \text{affine schemes}, \quad \alpha \mapsto U_\alpha.$$  

Equivalently there exists a natural bijection between isomorphism classes of deformations of $X$ and isomorphism classes of strict deformations of the diagram $S$.

**Definition 6.1.** A Reedy-Palamodov resolvent of $X$, relative to an affine open cover with nerve $N$ is a Reedy cofibrant resolution of the diagram $S$, of (6.1).

In particular, the results of previous sections apply to this situation and then $\text{Der}^*_K(R, R)$ is the DG-Lie algebra controlling deformations of $X$, where $R: N \to \text{CDGA}_{\leq 0}^K$ is a Reedy-Palamodov resolvent.

The name Reedy-Palamodov resolvent is clearly motivated by the large amount of common features with the usual resolvent considered in deformation theory of complex analytic spaces. In fact, a Reedy cofibrant resolution of $X$ over the nerve $N$ is a morphism of diagrams $R \to S$ over $N$ characterised by the following (redundant) list of properties:

1. for every $\alpha \in N$ we have $H^j(R_\alpha) = 0$ for every $j \neq 0$ and $H^0(R_\alpha) \cong \Gamma(U_\alpha, \mathcal{O}_X)$;
2. for every $\alpha \in N$ the DG-algebra $R_\alpha \in \text{CDGA}_{\leq 0}^K$ is cofibrant, and the natural map

$$\operatorname{colim}_{\gamma < \alpha} R_\gamma \to R_\alpha$$

is a cofibration.

Replacing in the above characterization cofibrations with semifree extensions and cofibrant algebra with semifree algebra, we recover precisely the algebraic analogue of Palamodov’s resolvent [21, 22], also called free DG-algebra resolution in [3, 5]. Thus we have proved the following result.
Theorem 6.2. Let $X$ be a separated scheme over a field $K$ of characteristic 0 and let $R \in \text{Fun}(\mathcal{N}, \text{CDGA}^<_{K})$ be a Reedy-Palamodov resolvent of $X$. Then the DG-Lie algebra $\text{Der}_K^*(R, R)$ controls the functor of infinitesimal deformations of $X$.

Writing down explicitly the resolvent can be very hard: in the following two illustrating examples we consider the smooth and the cuspidal rational curves, respectively.

Example 6.3 (Resolvent of $\mathbb{P}^1$). Let $x_0, x_1$ be a set of homogeneous coordinates in $\mathbb{P}^1$, then a Reedy-Palamodov resolvent over the nerve of the affine cover $\{x_0 \neq 0\} \cup \{x_1 \neq 0\}$ is given by

$$
\begin{array}{ccc}
\mathbb{K}[x] & \to & \mathbb{K}[x] \\
\downarrow & & \downarrow \\
\mathbb{K}[y] & \to & \mathbb{K}[x, y, e] \\
& & (xy - 1)
\end{array}
$$

where $x = x_1/x_0$, $y = x_0/x_1$, $\text{deg}(e) = -1$, $de = xy - 1$.

Example 6.4 (Resolvent of the cuspidal cubic). Let $X$ be the cuspidal cubic in $\mathbb{P}^2$ of equation $x_0^2 x_1 = x_2^3$, and consider the affine open cover

$$X = U_0 \cup U_1, \quad U_0 = \{x_0 \neq 0\}, \quad U_1 = \{x_1 \neq 0\}.$$ 

Then $U_{01} = \{x_0 x_1 \neq 0\} = \{x_2 \neq 0\}$ and via the isomorphism $\mathbb{C} \to U_0, w \mapsto [w, 1, w^3]$, we have:

$$
\begin{align*}
\Gamma(U_0, \mathcal{O}_X) &= \mathbb{K}[x, z]_{(z - x^3)} \simeq \mathbb{K}[w], \\
& \quad x = w = \frac{x_2}{x_0}, \quad z = w^3 = \frac{x_1}{x_0}, \\
\Gamma(U_1, \mathcal{O}_X) &= \mathbb{K}[x, z]_{(y^2 - x^3)} \simeq \mathbb{K}[y], \\
& \quad x = \frac{x_2}{x_1}, \quad y = \frac{x_0}{x_1}, \\
\Gamma(U_{01}, \mathcal{O}_X) &= \mathbb{K}[t, w]_{(tw - 1)} \simeq \mathbb{K}[w], \\
& \quad w = \frac{x_2}{x_0}, \quad t = \frac{x_0}{x_2}.
\end{align*}
$$

The corresponding diagram over the nerve is:

$$S : \begin{array}{ccc}
\mathbb{K}[x, y]_{(y^2 - x^3)} & \to & \mathbb{K}[t, w]_{(tw - 1)} \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
\mathbb{K}[x, y]_{(y^2 - x^3)} & \to & \mathbb{K}[t, w]_{(tw - 1)}
\end{array}$$

An easy computation shows that a possible Reedy-Palamodov resolvent $p : R \to S$ is:

$$
\begin{array}{ccc}
\mathbb{K}[x, y, e_1] & \to & \mathbb{K}[x, y, h, t, w, e_1, e_2, e_3, e_4] \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
\mathbb{K}[x, y]_{(y^2 - x^3)} & \to & \mathbb{K}[t, w]_{(tw - 1)} \\
\end{array}
$$

where: $x, y, h, t, w$ have degree 0; $e_1, e_2, e_3, e_4$ have degree $-1$;

$$
de_{e_1} = y^2 - x^3, \quad de_2 = hx - 1, \quad de_3 = tx - y, \quad de_4 = tw - 1;$$

$$p_{01}(x) = t^2, \quad p_{01}(y) = t^3, \quad p_{01}(h) = w^2, \quad p_{01}(t) = t, \quad p_{01}(w) = w.$$ 

It is interesting to notice that the Reedy cofibrant assumption forces to see the hyperbola $U_{01}$ as a complete intersection of 3 quadrics and a cubic in $\mathbb{K}^5$ and not as a plane affine conic.
The tangent and cotangent complexes

It is well known that to every noetherian separated finite-dimensional scheme $X$ over $\mathbb{K}$ are associated the tangent and cotangent complexes. Given a Reedy-Palamodov resolvent $R$ of $X$, the tangent complex is the class of $\text{Der}^1(R, R)$ in the homotopy category of DG-Lie algebras, and then by Theorem 6.2 it controls the deformation theory of $X$. Its cohomology $T^i(X)$ is called tangent cohomology \cite{21, 22}; by general results about deformation theory via DG-Lie algebras, $T^1(X)$ is the space of (classical) first order deformations, while $T^2(X)$ is the space of (classical) obstructions, cf. \cite[Thm. 5.1 and Thm. 5.2]{21}.

The cotangent complex $L_X$ is an object in the (unbounded) derived category of quasi-coherent sheaves and it can be used to compute the tangent cohomology by the formula $T^i(X) = \text{Ext}^i_X(L_X, \mathcal{O}_X)$; moreover $L_X$ has coherent cohomology and therefore each $T^i(X)$ is finite dimensional whenever $X$ is proper. The standard reference for the cotangent complex and for its application to deformations of schemes and diagrams is \cite{15}.

If $X = \text{Spec}(S)$ is an affine $\mathbb{K}$-scheme, then its cotangent complex is defined (up to quasi-isomorphism) as the sheaf associated to the $S$-module $\Omega_{R/\mathbb{K}} \otimes_R S$: \[ [\Omega_{R/\mathbb{K}} \otimes_R S] \in D(\text{QCoh}(X)) \]

where $R \to S$ is a cofibrant replacement in $\text{CDGA}_{\mathbb{K}}^{\leq 0}$ and $\Omega_{R/\mathbb{K}}$ denotes the DG-module of Kähler differentials over $R$.

According to \cite{3, 5} it is possible to describe a representative of the cotangent complex in terms of a Reedy-Palamodov resolvent also in the non affine case. Our goal is to present another construction relying on a certain model for a DG-enhancement for the unbounded derived category of quasi-coherent sheaves described in \cite{19}.

Recall that for every DG-algebra $S \in \text{CDGA}_{\mathbb{K}}^{\leq 0}$ there exists a model structure on the category $\text{DGMod}(S)$ of DG-modules where (\cite{7, 13}):

- weak equivalences are quasi-isomorphisms,
- fibrations are degree-wise surjective morphisms,
- a complex $\mathcal{F} \in \text{DGMod}(S)$ is cofibrant if and only if for every cospan $\mathcal{F} \xrightarrow{f} \mathcal{G} \xleftarrow{g} \mathcal{H}$ with $g$ a surjective quasi-isomorphism there exists a lifting $h: F \to \mathcal{H}$ such that $f = gh$,
- every DG-module is fibrant,
- cofibrations are degree-wise split injective morphisms with cofibrant cokernel.

Now, let $X$ be a Noetherian separated finite-dimensional scheme over a field $\mathbb{K}$, fix an open affine covering $\{U_i\}_{i \in I}$ together with its nerve $\mathcal{N}$ as defined in Section 6; consider the following diagram

\[
S_\alpha: \mathcal{N} \to \text{CDGA}_{\mathbb{K}}^{\leq 0}, \quad S_\alpha = \Gamma(U_\alpha, \mathcal{O}_X)
\]
as already defined in (6.1). A $S$-module consists of the following data:

- an object $\mathcal{F}_\alpha \in \text{DGMod}(S_\alpha)$ for every $\alpha \in \mathcal{N}$,
- a morphism $f_{\alpha\beta}: \mathcal{F}_\alpha \otimes_{S_\alpha} S_\beta \to \mathcal{F}_\beta$ in $\text{DGMod}(S_\beta)$ for every $\alpha \leq \beta$ in $\mathcal{N}$, satisfying the cocycle condition $f_{\beta\gamma} \circ (f_{\alpha\beta} \otimes_{S_\beta} 1_{S_\gamma}) = f_{\alpha\gamma}$ for every $\alpha \leq \beta \leq \gamma$ in $\mathcal{N}$.

Notice that in the above definition each map $f_{\alpha\beta}: \mathcal{F}_\alpha \otimes_{S_\alpha} S_\beta \to \mathcal{F}_\beta$ is equivalent to its adjoint morphism $\mathcal{F}_\alpha \to \mathcal{F}_\beta$ in $\text{DGMod}(S_\alpha)$, where the $S_\alpha$-module structure on $\mathcal{F}_\beta$ is given by $S_\alpha \to S_\beta$. 
A morphism $\varphi : F \rightarrow G$ between $S$-modules is the datum of a collection of morphisms $\{\varphi_\alpha : F_\alpha \rightarrow G_\alpha\}_{\alpha \in \mathcal{N}}$ such that the diagram

$$
\begin{array}{ccc}
F_\alpha \otimes_{S_\alpha} S_\beta & \xrightarrow{\varphi_\alpha} & G_\alpha \otimes_{S_\alpha} S_\beta \\
\downarrow f_{\alpha}\beta & & \downarrow g_{\alpha}\beta \\
F_\beta & \xrightarrow{\varphi_\beta} & G_\beta
\end{array}
$$

commutes in $\text{DGMod}(S_\beta)$. We shall denote by $\text{Hom}_S(F,G)$ the set of such morphisms, and by $\text{Mod}(S)$ the category of $S$-modules.

The objects we are mainly interested in are quasi-coherent $S$-modules.

**Definition 7.1** ([19, Definition 3.12]). In the above notation, an $S$-module $F \in \text{Mod}(S)$ is called quasi-coherent if for every $\alpha \leq \beta$ in $\mathcal{N}$ the map

$$f_{\alpha}\beta : F_\alpha \otimes_{S_\alpha} S_\beta \rightarrow F_\beta$$

is a quasi-isomorphism of DG-modules over $S_\beta$.

We shall denote by $\text{QCoh}(S)$ the full subcategory of quasi-coherent $S$-modules. Notice that the subcategory of quasi-coherent $S$-modules is closed both under $(C,FW)$-factorisations and $(CW,F)$-factorisations, so that it is well-defined the homotopy category $\text{Ho}(\text{QCoh}(S))$ as the Verdier quotient of cofibrant quasi-coherent $S$-modules modulo the class of quasi-isomorphisms. Moreover, there is a natural inclusion functor $\text{Ho}(\text{QCoh}(S)) \rightarrow \text{Ho}(\text{Mod}(S))$. Definition 7.1 is motivated by the following result, which was proven in [19, Thm. 3.9 and Thm. 5.7]

**Theorem 7.2.** The category $\text{Mod}(S)$ admits a model structure where both fibrations and weak equivalences are detected levelwise. Moreover, there exists an equivalence of triangulated categories

$$\Upsilon^* : D(\text{QCoh}(X)) \rightarrow \text{Ho}(\text{QCoh}(S)),$$

$$\Upsilon^*[F] = \{\Gamma(U_\alpha,F)\}_{\alpha \in \mathcal{N}},$$

where $\text{Ho}(\text{QCoh}(S))$ denotes the homotopy category of quasi-coherent $S$-modules.

For a detailed discussion of the quasi-inverse of the equivalence above we refer to [19]. Here we only point out that the equivalence $\Upsilon^*$ commutes in the natural way with restriction to subcoverings. If $\overline{\mathcal{N}} \subset \mathcal{N}$ is the nerve of a subcovering and $\overline{S} : \overline{\mathcal{N}} \rightarrow \text{CDGA}_{\leq 0}^{\infty,0}$ is the corresponding diagram, the natural restriction map $\text{QCoh}(S) \rightarrow \text{QCoh}(\overline{S})$ is a properly defined exact functor and by Theorem 7.2 the induced map $\text{Ho}(\text{QCoh}(S)) \rightarrow \text{Ho}(\text{QCoh}(\overline{S}))$ is an equivalence of triangulated categories.

By virtue of Theorem 7.2, it is convenient to describe the tangent and cotangent complexes in terms of $S$-modules. To this aim we first need to introduce the global analogue of derivations and of Kähler differentials.

### 7.1. Global derivations and global Kähler differentials

This subsection is devoted to introduce the global versions of derivations and Kähler differentials, in order to define the (homotopy classes of) tangent and cotangent complexes in terms of $S$-modules via the equivalence of Theorem 7.2.

We begin by defining for every morphism $\eta : R \rightarrow P$ of diagrams in $\text{Fun}(\mathcal{C},\text{CDGA}_{\leq 0}^{\infty,0})$

$$\text{Der}_{\mathcal{R}}^\eta(R,P) \subset \prod_{a \in \mathcal{C}} \text{Der}_{\mathcal{R}}^\eta(R_a,P_a)$$

the subset of sequences $\{\alpha_a\}_{a \in \mathcal{C}}$ such that for every morphism $f : a \rightarrow b$ we have $P_f\alpha_b = \alpha_a R_f$, and the structure of $R_a$-module on $P_a$ is induced by $\eta$. Notice that this is consistent
with (5.3). Similarly one can define

$$\text{Hom}_K^\alpha(F, G) \subset \prod_{\alpha \in \mathcal{N}} \text{Hom}_K^\alpha(F_i, G_i)$$

for every $F, G \in \text{Mod}(S)$.

It is clear that every diagram $R \xrightarrow{\eta} P \xrightarrow{\mu} T$ induces by composition two morphisms

$$\text{Der}_K^\alpha(R, P) \xrightarrow{\mu^*} \text{Der}_K^\alpha(R, T) \leftrightarrow \text{Der}_K^\alpha(P, T)$$

which formally satisfy the usual properties of derivations in the model category $\mathbf{CDGA}_{\mathbb{K}}^{\leq 0}$.

Recall that by [8, 23] for any given $S \in \mathbf{CDGA}_{\mathbb{K}}^{\leq 0}$, the functor of Kähler differentials admits a Quillen right adjoint given by the trivial extension:

$$\Omega_- \otimes_- S : \mathbf{CDGA}_{\mathbb{K}}^{\leq 0} \downarrow S \rightleftarrows \mathbf{DGMod}^{\leq 0}(S) : - \oplus S.$$

This adjoint pair easily generalizes to the case of diagrams. Let $X$ be a Noetherian separated finite-dimensional scheme over a field $\mathbb{K}$, fix an open affine covering $\{U_i\}_{i \in I}$ together with its nerve $\mathcal{N}$ as defined in Section 6. Now consider the corresponding diagram $S_\alpha \in \text{Fun}(\mathcal{N}, \mathbf{CDGA}_{\mathbb{K}}^{\leq 0})$ defined by

$$S_\alpha : \mathcal{N} \to \mathbf{CDGA}_{\mathbb{K}}^{\leq 0}, \quad S_\alpha = \Gamma(U_\alpha, \mathcal{O}_X)$$

as in (6.1). Then define the functor $\Omega_N^- \otimes_- S_\alpha : \text{Fun}(\mathcal{N}, \mathbf{CDGA}_{\mathbb{K}}^{\leq 0}) \downarrow S_\alpha \to \text{Mod}^{\leq 0}(S_\alpha)$ as follows:

- $\text{Mod}^{\leq 0}(S_\alpha) \subseteq \text{Mod}(S_\alpha)$ denotes the full subcategory of $S_\alpha$-modules concentrated in non-negative degrees; it admits a model structure such that any cofibrant object $X \in \text{Mod}^{\leq 0}(S_\alpha)$ is also cofibrant when regarded as an object in $\text{Mod}(S_\alpha)$, [19, Rem. 3.11].
- $(\Omega_N^- \otimes_- S_\alpha)_\alpha = \Omega_{R_\alpha} \otimes_{R_\alpha} S_\alpha$ for every $R_\alpha \in \text{Fun}(\mathcal{N}, \mathbf{CDGA}_{\mathbb{K}}^{\leq 0})$ and every $\alpha \in \mathcal{N}$.
- For every $\alpha \leq \beta$ the map $\Omega_{R_\alpha} \otimes_{R_\alpha} S_\alpha \otimes_{S_\alpha} S_\beta = \Omega_{R_\alpha} \otimes_{R_\alpha} S_\beta$ induces a quasi-isomorphism between $S_\alpha$ and $S_\beta$.

Notice that in the setting of Definition 7.7 we have $\Omega_N^- \otimes_- S_\alpha = \mathcal{L}_R$. Moreover, there exists a bi-natural isomorphism

$$\text{Hom}_K^\alpha(\Omega_N^- \otimes_P S_\alpha, F) \cong \text{Der}_K^\alpha(P, F)$$

for every $P \in \text{Fun}(\mathcal{N}, \mathbf{CDGA}_{\mathbb{K}}^{\leq 0})$ and every $F \in \text{Mod}^{\leq 0}(S_\alpha)$.

**Remark 7.3.** It is easy to show that the functor $\Omega_N^- \otimes_- S_\alpha : \text{Fun}(\mathcal{N}, \mathbf{CDGA}_{\mathbb{K}}^{\leq 0}) \downarrow S_\alpha \to \text{Mod}^{\leq 0}(S_\alpha)$ defined above admits a right Quillen adjoint as in the affine case. In particular, $\Omega_N^- \otimes_- S_\alpha$ maps Reedy-cofibrant diagrams to cofibrant $S_\alpha$-modules. Moreover, by Ken Brown’s Lemma it preserves weak equivalences between cofibrant objects.

**Lemma 7.4.** In the above setup, if $R$ is Reedy cofibrant and $\mu$ is a weak-equivalence, then $\text{Der}_K^\alpha(R, P) \xrightarrow{\mu^*} \text{Der}_K^\alpha(R, T)$ is a quasi-isomorphism. Moreover, if $\eta : R \to P$ is a weak equivalence between cofibrant objects in $\text{Fun}(\mathcal{N}, \mathbf{CDGA}_{\mathbb{K}}^{\leq 0})$, then:

1. the map $\eta^* : \text{Der}_K^\alpha(P, T) \to \text{Der}_K^\alpha(R, T)$ defined above is a quasi-isomorphism,
2. $\text{Der}_K^\alpha(R, R)$ and $\text{Der}_K^\alpha(P, P)$ are quasi-isomorphic as DG-Lie algebras.

**Proof.** It is an easy consequence of Remark 7.3 and of standard arguments, see [18, Rem. 6.9] and [19, Lemma 6.14].

In particular, by Lemma 7.4 it follows that in the setting of Corollary 5.6 the homotopy class of the DG-Lie algebra $\text{Der}_K^\alpha(R, R)$ does not depend on the choice of the Reedy cofibrant replacement $R$. 

Example 7.5. Let \( f: R \to S \) be a surjective morphism of cofibrant DG-algebras with ideal \( I \). Then the deformations of \( f \) are controlled by the DG-Lie algebra
\[
M = \{ \alpha \in \text{Der}_K^*(R, R) \mid \alpha(I) \subset I \} \cong \text{Der}_K^*(R, R) \times_{\text{Der}_S^*(R, S)} \text{Der}_S^*(S, S).
\]

Consider a factorisation \( f: R \overset{i}{\to} H \overset{p}{\to} S \) with \( i \) a cofibration and \( p \) a trivial fibration. Then \( R \to H \) is a Reedy cofibrant resolution of \( R \to S \) and we need to prove that the DG-Lie algebra \( M \) is quasi-isomorphic to
\[
L = \text{Der}_K^*(R, R) \times_{\text{Der}_S^*(R, H)} \text{Der}_S^*(H, H).
\]

The obvious composition maps give a commutative diagram of complexes
\[
\begin{array}{ccc}
\text{Der}_K^*(R, R) & \overset{\text{Der}_K^*(R, H)}{\longrightarrow} & \text{Der}_K^*(H, H) \\
\downarrow & & \downarrow \\
\text{Der}_K^*(R, R) & \overset{\text{Der}_K^*(R, S)}{\longrightarrow} & \text{Der}_K^*(H, S) \\
\downarrow & & \downarrow \\
\text{Der}_K^*(R, R) & \overset{\text{Der}_K^*(R, S)}{\longrightarrow} & \text{Der}_K^*(S, S)
\end{array}
\]

where the double head arrows denote surjective morphisms and every vertical arrow is a quasi-isomorphism. Notice that the assumption that \( S \) is cofibrant is used to ensure that the map \( \text{Der}_S^*(S, S) \to \text{Der}_S^*(H, S) \) is a quasi-isomorphism. By coglueing lemma we have two quasi-isomorphisms
\[
L \overset{l}{\longrightarrow} \text{Der}_K^*(R, R) \times_{\text{Der}_S^*(R, S)} \text{Der}_S^*(H, S) \overset{m}{\longrightarrow} M
\]

and an easy direct inspection shows that \( l \) is surjective. In order to finish the proof it is sufficient to observe that the fibre product of the above cospan is the DG-Lie algebra of derivations of the diagram \( R \to H \to S \), defined as in (5.3).

Example 7.6 (Derived functor of points). Given a morphism \( f: B \to \mathbb{K} \) in \( \text{CDGA}_{\mathbb{K}}^{\leq 0} \) we are interested to morphisms in the homotopy category
\[
B \to A \quad A \in \text{DGArt}_{\mathbb{K}}^{\leq 0}
\]
lifting \( f \). Given a cofibrant resolution \( p: R \to B \), the above morphisms can be interpreted as deformations of the diagram \( fp: R \to \mathbb{K} \) inducing a trivial deformation of \( R \). Denoting by \( I \subset R \) the kernel of \( fp \), by Examples 5.7 and 7.5 the corresponding DG-Lie algebra is equal to the homotopy fibre of the inclusion
\[
\{ \alpha \in \text{Der}_K^*(R, R) \mid \alpha(I) \subset I \} \to \text{Der}_K^*(R, R).
\]

7.2. The quasi-coherent \( S \)-module corresponding to the cotangent complex. Let \( X \) be a Noetherian separated finite-dimensional scheme over a field \( \mathbb{K} \), with a fixed open affine covering \( \{ U_i \}_{i \in I} \). Consider the diagram \( S \), as above together with a cofibrant replacement \( R \to S \) in \( \text{Fun}(X, \text{CDGA}_{\mathbb{K}}^{\leq 0}) \). Hence, according to Definition 6.1, \( R \) is a Reedy-Palamodov resolvent for \( X \).

Notice that by Lemma 7.4 the tangent complex \( \text{Der}_K^*(R, R) \) is well-defined in the homotopy category of DG-Lie algebras, i.e., it does not depend on the Reedy-Palamodov resolvent \( R \). Moreover, it is quasi-isomorphic (as a complex) to \( \text{Der}_K^*(R, S) \).

For what concerns the cotangent complex, we shall make use of the equivalence of Theorem 7.2, so that we introduce the definition in terms of the homotopy category of quasi-coherent \( S \)-modules.
Definition 7.7 (The cotangent complex). In the above notation, define the cotangent complex to be the class \([\mathcal{L}_R] \in \text{Ho}(\text{QCoh}(S)),\) where the \(S\)-module \(\mathcal{L}_R\) is defined by:

- \(\mathcal{L}_{R,\alpha} = \Omega_{R,\alpha} \otimes_{R,\alpha} S_\alpha\) for every \(\alpha \in \mathcal{N},\)
- for every \(\alpha \leq \beta\) the map \(l_{\alpha\beta}: \mathcal{L}_{R,\alpha} \otimes_{S_\alpha} S_\beta \to \mathcal{L}_{R,\beta}\) is obtained applying the functor \(\Omega_{-} \otimes_{S} -\) to the map \(R_\alpha \to R_\beta.\)

Observe that by Remark 7.3 the homotopy class \([\mathcal{L}_R]\) does not depend on the choice of the resolvent. Therefore, in order to prove that Definition 7.7 is well-posed we only need to show that the \(S\cdot\)-module \(\mathcal{L}_R\) is quasi-coherent in the sense of Definition 7.1. We proceed by proving a series of preliminary lemmas.

The assumptions in the following lemma are motivated by the fact that, if \(U = \text{Spec}(A)\) is an affine scheme and \(V = \text{Spec}(B) \subset U\) is an open affine subset, then the morphism \(A \to B\) is flat and the natural map \(B \otimes_A B \to B\) is an isomorphism.

**Lemma 7.8.** Let \(A \to B\) be a flat morphism in \(\text{CDGA}_{\mathbb{K}}^{\leq 0}\) such that the natural map \(B \otimes_A B \to B\) is a weak equivalence. Consider a commutative diagram

\[
\begin{array}{ccc}
R & \xrightarrow{i} & S \\
\downarrow & & \downarrow \\
A & \xrightarrow{j} & B
\end{array}
\]

with the vertical arrow cofibrant replacements and \(i\) a cofibration. Then \(\Omega_R \otimes_R B \to \Omega_S \otimes_S B\) is a trivial cofibration of \(B\)-modules.

**Proof.** Let \(j: S \to S \otimes_R S\) be the push-out of \(i\) by itself. We first show that \(j\) is a trivial cofibration. By model category axioms cofibrations are closed under pushouts, so that we only need to prove that \(j\) is a weak equivalence. Since the category \(\text{CDGA}_{\mathbb{K}}^{\leq 0}\) is left proper and \(i: R \to S\) is a cofibration, the natural maps

\[
\begin{aligned}
S \otimes_R S &\to S \otimes_R B, & S = S \otimes_R R &\to S \otimes_R A,
\end{aligned}
\]

are weak equivalences. By the universal property of push-out we have a diagram

\[
\begin{array}{ccc}
R & \xrightarrow{i} & S \\
\downarrow & & \downarrow \\
A & \xrightarrow{j} & B \\
\downarrow & & \downarrow \\
S \otimes_R A & \xrightarrow{q} & S \otimes_R B
\end{array}
\]

and \(q\) is a weak equivalence by the 2 out of 3 property. Now, since \(A \to B\) is flat, the composite map

\[
S \otimes_R S \to S \otimes_R B = (S \otimes_R A) \otimes_A B \to B \otimes_A B
\]

is a weak equivalence. Therefore the lemma follows by the 2 out of 3 property applied to the commutative diagram

\[
\begin{array}{ccc}
S & \xrightarrow{j} & S \otimes_R S \\
\downarrow & & \downarrow \\
S & \xrightarrow{id} & B \otimes_A B \\
\downarrow & & \downarrow \\
S & \xrightarrow{S} & B
\end{array}
\]

By Remark 7.3 the morphism \(\Omega_R \otimes_R B \to \Omega_S \otimes_S B\) is a cofibration (hence injective); in view of the standard exact sequence

\[
\Omega_R \otimes_R B \to \Omega_S \otimes_S B \to \Omega_{S/R} \otimes_S B \to 0,
\]
it is sufficient to show that $\Omega_{S/R} \otimes_S B$ is acyclic. Since $S \to S \otimes_R S$ is a trivial cofibration the module
\[ \Omega_{S \otimes_R S} = \Omega_{S/R} \otimes_R S = \Omega_{S/R} \otimes_S S \otimes_R S \]
is acyclic. Since $S \otimes_R S \to B \otimes_A B \to B$ is a weak equivalence and $\Omega_{S/R}$ is cofibrant as an $S$-module, there exists a weak equivalence
\[ \Omega_{S/R} \otimes_S S \otimes_R S \to \Omega_{S/R} \otimes_S B. \]

**Proposition 7.9.** Let $A \to B$ be a flat morphism in $\text{CDGA}_{K}^{<0}$ such that the natural map $B \otimes_A B \to B$ is a weak equivalence. Consider a commutative diagram
\[
\begin{array}{ccc}
R & \to & S \\
\downarrow & & \downarrow \\
A & \to & B
\end{array}
\]
with the vertical arrow cofibrant replacements. Then $\Omega_R \otimes_R B \to \Omega_S \otimes_S B$ is a weak equivalence.

**Proof.** By taking a $(C,FW)$-factorisation of the natural map $R \otimes S \to S$ we have the diagrams
\[
\begin{array}{ccc}
T & \to & S \\
\downarrow & & \downarrow \\
R & \to & S \\
\downarrow & & \downarrow \\
A & \to & B
\end{array}
\quad \quad \quad
\begin{array}{ccc}
T & \to & S \\
\downarrow & & \downarrow \\
B & \to & B \\
\downarrow & & \downarrow \\
B & \id & B
\end{array}
\]
with $j$ cofibration and $p$ a trivial fibration admitting a cofibration $h: S \to T$ as a section. Hence by Lemma 7.8 the maps
\[ \Omega_R \otimes_R B \to \Omega_T \otimes_T B \leftarrow \Omega_S \otimes_S B \]
induced by $j$ and $h$ are trivial cofibrations. Moreover, the composition
\[ \Omega_S \otimes_S B \to \Omega_T \otimes_T B \to \Omega_S \otimes_S B \]
is the identity being $h$ a section of $p$; therefore $\Omega_T \otimes_T B \to \Omega_S \otimes_S B$ is a weak equivalence.

The statement follows by considering the composition $\Omega_R \otimes_R B \to \Omega_T \otimes_T B \to \Omega_S \otimes_S B$.

We are now ready to prove that Definition 7.7 is well-posed. Recall that by Definition 7.1 a $S$-module $\mathcal{F} \in \text{Mod}(S)$ is called quasi-coherent if the map $f_{\alpha \beta}: \mathcal{F}_\alpha \otimes_{S_\alpha} S_\beta \to S_\beta$ is a quasi-isomorphism for every $\alpha \leq \beta$ in $\mathcal{N}$.

**Theorem 7.10.** Let $X$ be a Noetherian separated finite-dimensional scheme over a field $K$, with a fixed open affine covering $\{U_i\}_{i \in I}$. Consider the associated diagram $S$, as in (6.1), together with a Reedy-Palamodov resolvent $R \to S$. Then the $S$-module $\mathcal{L}_R$ defined in 7.7 is cofibrant and quasi-coherent.

**Proof.** Since $\mathcal{L}_R = \Omega^N_{R \otimes_R S}$, the statement immediately follows by Remark 7.3 and Proposition 7.9.

Because of Theorem 6.2, it is important to concretely understand the homotopy class of the DG-Lie algebra of derivations of a Reedy-Palamodov resolvent. To this aim, the next result relates the cohomology of derivations of a Reedy-Palamodov resolvent with the cotangent complex.
Theorem 7.11. Let \( X \) be a Noetherian separated finite-dimensional scheme over a field \( \mathbb{K} \), with a fixed open affine covering \( \{ U_i \}_{i \in I} \) and its nerve \( \mathcal{N} \). Consider the associated diagram \( S \) as in (6.1), together with a Reedy-Palamodov resolvent \( R \rightarrow S \). Then there exist an isomorphism

\[
H^* (\text{Der}_k^*(R, R)) \cong H^* (\text{Hom}_S^*(L_R, S)) .
\]

Proof. By Lemma 7.4 the map

\[
\text{Der}_k^*(R, R) \rightarrow \text{Der}_k^*(R, S) \cong \text{Hom}_R^*(\Omega_{R}^{\mathcal{N}}, S) \cong \text{Hom}_S^*(\Omega_{R}^{\mathcal{N}} \otimes_R S, S)
\]

is a quasi-isomorphism.

It is worth to point out that combining Theorem 6.2 and Theorem 7.11 we have that the space of first order deformations is nothing but \( \text{Ext}_{R}^{2}(\mathbb{L}_{X}, \mathcal{O}_{X}) \) and the obstructions are contained in \( \text{Ext}_{R}^{2}(\mathbb{L}_{X}, \mathcal{O}_{X}) \), where \( \mathbb{L}_{X} \in D(\text{QCoh}(X)) \) and \( \mathbb{T}^{\bullet}_{\mathbb{L}_{X}} = [\mathbb{L}_{R}] \).

8. A Remark about Deformations of Maps (after Horikawa, Ran and Pridham)

The argument used in Section 6 easily extends to every morphism of separated schemes, considered as a contravariant functor from the direct Reedy category \( \{ 0 \rightarrow 1 \} \) to the category of separated schemes. More precisely, given any morphism \( f: X \rightarrow Y \) of separated schemes we can find a family of pairs \( \{(U_i, V_i)\}_{i \in I} \) such that:

1. the family \( \{U_i\} \) is an affine open cover of \( X \),
2. the family \( \{V_i\} \) is an affine open cover of \( Y \),
3. \( f(U_i) \subset V_i \) for every \( i \in I \).

We then define the nerve \( \mathcal{N} \) as the family of finite subsets \( \alpha \subset I \) such that:

\[
\text{colim}_{\gamma \subset \alpha} Q_{\gamma, 0} \rightarrow Q_{\alpha, 0}, \quad \text{colim}_{\gamma \subset \alpha} Q_{\gamma, 1} \otimes_{\text{colim}_{\gamma \subset \alpha} Q_{\gamma, 0}} Q_{\alpha, 0} \rightarrow Q_{\alpha, 1}
\]

are cofibrations in \( \text{CDGA} \leq 0 \). Therefore \( Q_{\cdot, \cdot} \) is cofibrant if and only if \( Q_{\cdot, 0} \) is cofibrant and \( Q_{\cdot, 1} \) is a cofibration.

In particular if \( R_{\cdot} \) is a resolution for \( f: X \rightarrow Y \), i.e., a Reedy cofibrant resolution of \( S_{\cdot, \cdot} \), then \( R_{\cdot, 0} \) is a resolution of \( Y, R_{\cdot, 1} \) is a resolution of \( X \) and \( R_{\cdot, 0} \rightarrow R_{\cdot, 1} \) is a cofibration, cf. Example 5.7. This implies for instance, considering \( R_{\cdot, 1} \) as a \( R_{\cdot, 0} \)-module, that the natural map

\[
\sigma: \text{Der}^*(R_{\cdot, 1}, R_{\cdot, 1}) \rightarrow \text{Der}^*(R_{\cdot, 0}, R_{\cdot, 1})
\]

is surjective, while the natural map

\[
\tau: \text{Der}^*(R_{\cdot, 0}, R_{\cdot, 0}) \rightarrow \text{Der}^*(R_{\cdot, 0}, R_{\cdot, 1})
\]

is injective. Therefore we have a short exact sequence

\[
0 \rightarrow \text{Der}^*(R_{\cdot, \cdot}, R_{\cdot, \cdot}) \rightarrow \text{Der}^*(R_{\cdot, 0}, R_{\cdot, 0}) \oplus \text{Der}^*(R_{\cdot, 1}, R_{\cdot, 1}) \overset{\sigma - \tau}{\longrightarrow} \text{Der}^*(R_{\cdot, 0}, R_{\cdot, 1}) \rightarrow 0 .
\]

We have proved that the DG-Lie algebra on the left controls the deformations of \( f \). Thus, setting \( T^{i}(f) = H^{i}(\text{Der}^*(R_{\cdot, \cdot}, R_{\cdot, \cdot})) \) we have that \( T^{1}(f) \) is the space of first order deformations, while \( T^{2}(f) \) is the obstruction space. The resulting cohomology long exact sequence (8.1)

\[
\ldots T^{i}(f) \rightarrow T^{i}(X) \oplus T^{i}(Y) \rightarrow H^{i}(\text{Der}^*(R_{\cdot, 0}, S_{\cdot, 1})) \rightarrow T^{i+1}(f) \rightarrow T^{i+1}(X) \oplus T^{i+1}(Y) \ldots
\]
is familiar to most people working in deformation theory, since the same has been proved over the field of complex numbers by Horikawa [12] in the smooth case (see also [20, p. 184] and [14, Rem. 5.2]), by Ran [25] in the reduced case and in full generality by Pridham (Theorem 3.2 and Lemma 3.3 applied to Example 3.3 of [24]).

The same considerations hold, mutatis mutandis, for every diagram \( X : \text{C}^{\text{op}} \rightarrow \text{Schemes} \) of separated \( K \)-schemes over the opposite of a direct Reedy category: for simplicity of notation, for every morphism \( f : a \rightarrow b \) in \( C \) we shall use the same symbol \( f : X_b \rightarrow X_a \) to denote the corresponding morphism of schemes \( X(f) \). Here the role of affine open subsets is played by elements \( U \cdot \in \prod_{a \in \text{C}} \{ \text{affine open subsets of} \, X_a \} \) such that \( f(U_b) \subset U_a \) for every morphism \( f : a \rightarrow b \) in \( C \). The fact that \( C \) is Reedy direct easily implies that there exists a “covering” \( \{ U_i \} \) of \( X \) made by elements as above, with corresponding nerve \( N \). Finally the deformations of the diagram of schemes \( X \) are the same as the deformations of the diagram of algebras

\[ S_a \cdot : N \times C \rightarrow \text{CDGA}_K^{\leq 0}, \quad S_{a,a} = \Gamma(U_{a,a}, \mathcal{O}_{X_a}) \]

that can be studied as in Section 5, since \( N \times C \) is direct Reedy.

Acknowledgement. Both authors thank Donatella Iacono for useful discussions on the subject of this paper.
