Supporting Information

ABSTRACT: Cocaine esterase (CocE) is known as the most efficient natural enzyme for cocaine hydrolysis. The major obstacle to the clinical application of wild-type CocE is the thermostability with a half-life of only ∼12 min at 37 °C. The previously designed T172R/G173Q mutant (denoted as enzyme E172–173) with an improved in vitro half-life of ∼6 h at 37 °C is currently in clinical trial Phase II for cocaine overdose treatment. Through molecular modeling and dynamics simulation, we designed and characterized a promising new mutant of E172–173 with extra L196C/I301C mutations (denoted as enzyme E196–301) to produce cross-subunit disulfide bonds that stabilize the dimer structure. The cross-subunit disulfide bonds were confirmed by X-ray diffraction. The designed L196C/I301C mutations have not only considerably extended the in vitro half-life at 37 °C to >100 days, but also significantly improved the catalytic efficiency against cocaine by ∼150%. In addition, the thermostable E196–301 can be PEGylated to significantly prolong the residence time in mice. The PEGylated E196–301 can fully protect mice from a lethal dose of cocaine (180 mg/kg, LD100) for at least 3 days, with an average protection time of ∼94 h. This is the longest in vivo protection of mice from the lethal dose of cocaine demonstrated within all studies using an exogenous enzyme reported so far. Hence, E196–301 may be developed to become a more valuable therapeutic enzyme for cocaine abuse treatment, and it demonstrates that a general design strategy and protocol to simultaneously improve both the stability and function are feasible for rational protein drug design.

Cocaine overdose and addiction have resulted in serious medical and social problems in modern society.1 So far, there is no anticocaine medication approved by the Food and Drug Administration (FDA).2,3 Cocaine causes its physiological effects by binding with the dopamine transporter and, thus, blocking dopamine reuptake. The disastrous medical and social consequences of cocaine abuse have made a high priority the development of an anticocaine medication. However, despite decades of efforts, the classical pharmacodynamic approach has failed to yield a truly useful small-molecule receptor/transporter antagonist. The alternative pharmacokinetic approach is to interfere with the delivery of cocaine to its receptors and/or accelerate its metabolism in the body.2,4–8 It would be an ideal anticocaine medication to develop an exogenous enzyme which can accelerate cocaine metabolism and produce biologically inactive metabolites.

Bacterial cocaine esterase (CocE) was recognized as the most efficient natural enzyme for hydrolyzing the naturally occurring (−)-cocaine.9 No any other natural esterase has a catalytic activity for cocaine comparable to that of CocE. Studies have shown that CocE can help to prevent extreme cocaine toxicity and even from the lethal effects of cocaine.10 However, a major obstacle to the clinical application of CocE is the thermostability of wild-type CocE with a half-life of only ∼12 min at physiological temperature (37 °C).11 It is highly desirable to develop thermostable mutants of CocE for therapeutic treatment of cocaine abuse (overdose and addiction). In fact, thermal stability is a well-known common problem in protein drug development.11 In general, the more thermally stable a protein drug, the longer shelf half-life the protein drug can have.

Generally speaking, the thermal stability of a protein could be improved by enhancing the weak interactions inside the enzyme through either noncovalent forces, such as hydrogen bonds,12 or covalent linkage, such as disulfide bonds.13 Particularly for an enzyme, besides improving its stability, it is also important to maintain the catalytic activity of the enzyme. However, it is much more challenging to engineer an enzyme with an improved stability without decreasing the catalytic activity.14–16 In general, according to the commonly recognized
"stability-function trade-off" theory/hypothesis, protein residues that contribute to catalysis or ligand binding are not optimal for protein stability and, thus, there is a balance between the stability and function. Indeed, extensive studies demonstrated that thermostabilizing mutations of enzymes decreased the catalytic activities, and that mutations improving the catalytic activities decreased the thermal stability. Nevertheless, some CocE mutants with an improved thermal stability have successfully been designed and discovered in recently reported studies, and these thermostable mutants did not decrease, or only slightly decreased, the catalytic efficiency ($k_{cat}/K_M$) of CocE against cocaine. Further animal behavior studies revealed that these CocE mutants are promising in development of an enzyme therapy for cocaine abuse.

Notably, one of the reported thermostable mutants of CocE, i.e. the T172R/G173Q mutant (known as drug RBP-8000, with ClinicalTrials.gov Identifier of NCT01846481 in clinical development) designed through our computational modeling and simulations, has been advanced to the randomized, double-blind, placebo controlled clinical trial phase II (http://www.clinicaltrials.gov/ct2/show/NCT01846481) for cocaine overdose treatment. The T172R/G173Q mutant (denoted as enzyme E172–173 here for convenience) was designed through introducing favorable noncovalent forces including a hydrogen bond between domains I and II of the protein. This CocE mutant has an in vitro half-life of ~6 h at 37 °C without decreasing the catalytic activity of CocE against cocaine. The half-life of ~6 h at 37 °C is long enough for cocaine overdose treatment, because one just needs to use the enzyme to rapidly detoxify cocaine. However, for cocaine addiction treatment, one would like to have a highly efficiently cocaine-metabolizing enzyme in the body with a residence time as long as possible. With a highly efficiently cocaine-metabolizing enzyme in the body, whenever a cocaine abuser uses cocaine again, the enzyme would rapidly metabolize cocaine so that the cocaine abuser would not feel the stimulate effects of cocaine.

To further develop an improved therapeutic enzyme for cocaine abuse treatment, one would like to both extend the half-life of E172–173 at 37 °C and improve the catalytic efficiency against cocaine. It has been shown that the thermal stability of E172–173 at 37 °C can be enhanced by extra mutations on E172–173. However, none of the reported extra mutations on E172–173 improved the catalytic efficiency against cocaine. Here we report arationally designed new mutant of E172–173, which has not only considerably extended the in vitro half-life at 37 °C, but also significantly improved the catalytic efficiency against cocaine. The new CocE mutant (i.e. the T172R/G173Q/L196C/I301C mutant of CocE, denoted as enzyme E196–301 for convenience) was modified further via PEGylation in order to extend the in vivo residence time of the enzyme. The PEGylated E196–301 was used to fully protect mice from a lethal dose of cocaine (180 mg/kg, LD100) for at least 3 days, indicating that it might be a more promising enzyme candidate for development of novel anticocaine therapeutics.

## RESULTS AND DISCUSSION

**Mutant Design: Insights from Molecular Modeling.**

We first aimed to stabilize the dimer structure of E172–173 and then analyzed the possibly stabilized dimer structure and estimated how the activity of the dimer would change. Our computational design strategy relied on the molecular dynamics (MD)-simulated dimer structure of E172–173 and the idea that the dimer structure can be stabilized by introducing disulfide bonds between the two subunits of the dimer. So, we carried out a sufficiently long MD simulation (50 ns) on the E172–173 dimer structure in order to obtain a dynamically stable dimer structure. To search for appropriate mutational sites to introduce the cross-subunit disulfide bonds, a self-developed script was used to scan the key intranuclear distances between the $Ca$ atoms of the residues on the dimer interface from the collected snapshots of the MD trajectory. Essentially, each pair of residues from different subunits was evaluated computationally for the simulated $Ca$–$Ca$ distance. If the simulated $Ca$–$Ca$ distance was within 7 Å, the pair of the residues would be checked manually for further evaluation of the detailed interactions. The most hopeful pair of residues may be mutated to cysteine for introducing possible cross-subunit disulfide bond(s).

Based on the analysis of the MD trajectory, L196C/I301C mutations satisfied all of the structural requirements. Summarized in Table 1 are the maximum, minimum, and average values of the $Ca$–$Ca$ distances associated with the stable MD trajectory (10 to 50 ns) in comparison with the corresponding $Ca$–$Ca$ distances in the X-ray crystal structure.

### Table 1. Maximum, Minimum, and Average $Ca$–$Ca$ Distances between Key Residues in the E172-173 Dimer Obtained from the 50 ns MD Simulation in Comparison with the Corresponding $Ca$–$Ca$ Distances in the X-ray Crystal Structure

| $Ca$–$Ca$ Distances (Å) | E172-173 structure | L196a–I301b | L196b–I301a |
|--------------------------|---------------------|--------------|--------------|
| crystal structure of E172-173 | 7.29 | 7.20 |
| MD-simulated E172-173 structure (50 ns MD) | max. 10.85 | 7.19 |
| | min. 5.16 | 4.51 |
| | avg. 7.15 | 5.44 |

T172R/G173Q CocE (E172–173) crystal structure (PDB ID: 3I2F).

*Fully relaxed MD simulation of the E172–173 dimer structure starting from the crystal structure.*

average values of the $Ca$–$Ca$ distances associated with the stable MD trajectory (10 to 50 ns) in comparison with the corresponding $Ca$–$Ca$ distances in the X-ray crystal structure. As seen in Table 1, the detailed analysis of the MD trajectory predicted that extra L196C/I301C mutations on E172–173 may introduce the desirable cross-subunit disulfide bonds between the two subunits of the E172–173 dimer. Depicted in Figure 1A are the simulated time-dependent $Ca$–$Ca$ distances for the pair of residues. Depicted in Figure 1B is the MD-simulated E172–173 dimer structure consisting of subunits a and b. Figure 1C is the detailed information about the MD-simulated E172–173 dimer structure concerning this important pair of residues. The interface between the two subunits is mainly composed of some residues from all of the three domains (I, II, and III) in the form of $a$-helices, $b$-sheets, and loops. L196 is located on one $a$-helix (E184-N197) in domain II, I301 is located on a loop in domain I.

According to the locations of these residues, it is highly possible to introduce a pair of cross-subunit disulfide bonds (C196a-C301b and C301a-C196b) through the L196C/I301C mutations on E172–173. The computationally designed new mutant, i.e. the T172R/G173Q/L196C/I301C mutant (denoted as enzyme E196–301 for convenience), may have a pair of cross-subunit disulfide bonds: one between C196 of subunit a (C196a) and C301 of subunit b (C301b), and the other...
between C301 of subunit a (C301a) and C196 of subunit b (C196b). It is also interesting to note that residue I301 is on a loop, implying that the loop flexibility may help to form the desirable cross-subunit disulfide bonds. In addition, molecular modeling and X-ray structural analysis (see below) of the dimer structure of the T172R/G173Q/L196C/I301C mutant also suggested that the extra L196C/I301C mutations could slightly increase the size of the active site cavity of the enzyme and, thus, might improve the catalytic activity.

**In Vitro Characterization of the Designed T172R/G173Q/L196C/I301C Mutant.** Based on the computational insights, we carried out wet experimental tests, including site-directed mutagenesis, protein expression, purification, and enzyme activity assays on the T172R/G173Q and T172R/G173Q/L196C/I301C mutants of CocE. For comparison, we also prepared and characterized the T172R/G173Q/G4C/S10C mutant which has been known to have a pair of cross-subunit disulfide bonds. All of the mutants were expressed similarly well. To minimize the possible systematic experimental errors of the kinetic data, we simultaneously prepared and characterized all of the three mutants under the same experimental conditions, which allowed us to fairly compare their catalytic activity against (−)-cocaine. Michaelis–Menten kinetics of the enzymatic hydrolysis of (−)-cocaine was determined by performing the sensitive radiometric assays using [3H](−)-cocaine (labeled on its benzene ring) with varying concentrations of the substrate. Depicted in Figure 2 are the measured kinetic data, and summarized in Table 2 are the kinetic parameters determined at 37 °C.

**Figure 2.** Plots of measured initial reaction rates (represented in μM min⁻¹ per nM enzyme at 37 °C, with error bars) versus the substrate concentration for (−)-cocaine hydrolysis catalyzed by CocE mutants: (A) T172R/G173Q; (B) T172R/G173Q/G4C/S10; (C) T172R/G173Q/L196C/I301C.

| CocE mutant | kₗ (min⁻¹) | Kₘ (μM) | kₗ/Kₘ (min⁻¹ M⁻¹) |
|-------------|-----------|--------|------------------|
| T172R/G173Q | 2600      | 2.9    | 9.2 x 10⁸        |
| T172R/G173Q/G4C/S10C | 2340 | 2.1  | 1.1 x 10⁹        |
| T172R/G173Q/L196C/I301C | 3450 | 1.5  | 2.3 x 10⁹        |

*The kinetic analysis was performed at 37 °C.*
T172R/G173Q mutant, the T172R/G173Q/G4C/S10C mutant has a slightly smaller $k_{\text{cat}}$ value (2340 min$^{-1}$) and a slightly smaller $K_M$ value (2.1 μM). Overall, the catalytic efficiency ($k_{\text{cat}}/K_M$) changed about 20% (from 9.2 × 10$^8$ min$^{-1}$ M$^{-1}$ to 1.1 × 10$^8$ min$^{-1}$ M$^{-1}$). Interestingly, the new mutant (T172R/G173Q/L196C/I301C) designed in the present study has both a significantly increased $k_{\text{cat}}$ value (3450 min$^{-1}$) and a significantly smaller $K_M$ value (1.5 μM). As a result, the catalytic efficiency ($k_{\text{cat}}/K_M = 2.3 \times 10^9$ min$^{-1}$ M$^{-1}$) of the T172R/G173Q/L196C/I301C mutant has a ~150% improvement from that ($k_{\text{cat}}/K_M = 9.2 \times 10^8$ min$^{-1}$ M$^{-1}$) of the T172R/G173Q mutant under the current clinical development.

Based on the encouraging kinetic data, the purified protein of the T172R/G173Q/L196C/I301C mutant was tested for the thermal stability at 37 °C. For this purpose, the enzyme was incubated at 37 °C, and the catalytic activity of the incubated enzyme against cocaine was assayed at different time points. As seen in Figure 3, the enzyme showed a relatively faster decrease of the activity (around 20%) during the first a few days, compared to the last 90 days. The relatively faster decrease of the activity during the first a few days is likely due to the possibility that certain percentage of the mutant protein molecules had not yet formed the expected cross-subunit disulfide bonds before the thermal stability test. Although the cross-subunit disulfide bonds were expected to form spontaneously (as no extra oxidation reagent was employed in this study to facilitate the disulfide bond formation), a small percentage of the new mutant (T172R/G173Q/L196C/I301C) molecules did not really form the cross-subunit disulfide bonds. Those T172R/G173Q/L196C/I301C mutant molecules without the cross-subunit disulfide bonds could lose the activity more rapidly, like the T172R/G173Q mutant which has an in vitro half-life of ~6 h at 37 °C.11 However, after the first few days, the enzyme activity decreased very slowly. Within the last 90 days, the enzyme activity decreased for only 15%.

Overall, the enzyme still retained more than 60% of the enzyme activity after incubation at 37 °C for 100 days, indicating that the in vitro half-life of the T172R/G173Q/L196C/I301C mutant at 37 °C should be longer than 100 days.

**Confirmation of the Cross-Subunit Disulfide Bonds.**

With the encouraging data about the significant improvement in both the catalytic activity and thermal stability at 37 °C, we have determined the crystal structure of the T172R/G173Q/L196C/I301C mutant in order to directly confirm the formation of the cross-subunit disulfide bonds between L196C and I301C.

The CocE mutant crystallized with one monomer in the asymmetric unit, but a symmetry related molecule forms an extensive interface, burying over 1900 Å$^2$ of solvent-accessible surface area as calculated by the PISA server.29 The dimer formed by these two molecules (Figure 4A and B) corresponds to previously reported structures of unlinked (PDB 3PUH) and covalently linked (PDB 3PUI) CocE dimers.26 Thus, the expected homodimer was formed in the crystals. Initial difference maps using the rigidly placed (without refinement) CocE mutant structure with glycine residues substituted at residue positions 196 and 301 showed strong positive Fo-Fc difference electron density for the cysteine side chains at the dimer interface (Figure 4C) consistent with disulfide bond formation. Subsequent refinement of the model with cysteine residues introduced at these positions and no disulfide restraints gave well-defined weighted 2Fo-Fc density and excellent geometry consistent with disulfide bond formation across the subunits (Figure 4D, see Figure 4A and B). The sulfur-to-sulfur distance is 2.0 Å and the dihedral angle is 94°. In summary, the crystal structure of the enzyme unambiguously confirms the presence of the engineered intersubunit disulfide bonds. Since the dimer axis corresponds to a crystallographic 2-fold axis (space group P6$_2$22), the structure was also refined in a lower symmetry group (P6$_3$), which places a disulfide-linked dimer in the asymmetric unit and does not therefore impose symmetry on the model. This refinement resulted in geometry for the two disulfide bonds that is nearly identical to that present in the dimer on the crystallographic 2-fold axis (Supporting Information Figure S3), eliminating the possibility of any artifact from this placement.

**Structure–activity correlation.** Superposition between the X-ray crystal structures of E172-173 (representing the
T172R/G173Q mutant) and E196-301 (representing the T172R/G173Q/L196C/I301C mutant) revealed a RMSD value of 0.299 Å, indicating the high similarity of the two protein structures. However, the superposition also revealed a slight shift of two α-helices (H2 and H3 in domain II) in E196-301 compared to that in E172-173 (see Figure S1 of Supporting Information). The shift created a slightly enlarged active-site cavity in E196-301, which could possibly favor the catalytic reaction process. A slightly larger active site could better accommodate such a large substrate like cocaine and, thus, make the enzyme more active against cocaine; the similar type of structure—activity correlation was noted for our previously designed mutants of human butyrylcholinesterase (BChE).31 The BChE mutants with a slightly larger active site have a significantly improved catalytic efficiency against cocaine without changing substrate specificity.31,32

To further understand why E196-301 has an improved catalytic activity against cocaine compared to E172-173, we needed to perform MD simulations on the transition state (TS1) for the initial reaction step of (−)-cocaine hydrolysis catalyzed by E172-173 and E196-301. Previous computational studies33 on the catalytic reaction mechanism for wild-type CocE-catalyzed hydrolysis of (−)-cocaine revealed that the CocE-catalyzed cocaine hydrolysis is initialized by the nucleophilic attack on the carbonyl carbon of (−)-cocaine benzoyl ester by the hydroxyl oxygen of Ser117, and that the transition state is stabilized by hydrogen bonding of the carbonyl oxygen of cocaine benzoyl ester with the hydroxyl group of Y44 side chain and the NH group of the Y118 backbone.33 The (−)-cocaine hydrolysis catalyzed by E172-173 or E196-301 is expected to follow the same catalytic reaction mechanism, as the residues #196 and #301 are all far away from the active site. Based on the established mechanistic understanding, the stronger the hydrogen bonding of the carbonyl oxygen of the substrate with Y44 side chain and Y118 backbone, the more active the enzyme.

Our general strategy and protocol for performing MD simulation on a transition state of enzymatic reaction using the classical force field have been described in detail elsewhere.4,35 Based on the protocol,34 the lengths of the transition bonds (i.e., the covalent bonds that gradually form or break during the reaction step associated with the transition state) in the transition state are restrained according to the previous QM/MM reaction-coordinate calculations, assuming that these bond lengths do not significantly change after the mutations. The transition-state modeling in the present study was based on our QM/MM-optimized TS1 structure33 for CocE-catalyzed hydrolysis of (−)-cocaine. It is reasonable to assume that the transition bond lengths in the TS1 structure will not significantly change after the T172R/G173Q or T172R/G173Q/L196C/I301C mutations. So, we carried out the MD simulations on the TS1 structures corresponding to E172-173 and E196-301, with the transition bond lengths restrained.

Depicted in Figure S2 of Supporting Information are the simulated time-dependent H−O distances (relevant to the hydrogen bonds) in E172-173 and E196-301 during the MD simulations for 50 ns. The detailed analysis of the key H−O distances between enzyme residues and cocaine is summarized in Table 3. In E172-173, the H−O distance between CocO and Y44HH was 3.02 Å in maximum, 1.44 Å in minimum, and 1.87 Å in average, while the H−O distance between CocO and Y114H was 3.14 Å in maximum, 1.61 Å in minimum, and 2.16 Å in average. In E196-301, the H−O distance between Y44HH and CocO was 3.17 Å in maximum, 1.44 Å in minimum, and 1.80 Å in average, while the H−O distance between CocO and Y114H was 2.89 Å in maximum, 1.61 Å in minimum, and 2.13 Å in average. According to these simulated H−O distances, the H−O distances of the two hydrogen bonds in E196-301 are all shorter than the corresponding ones in E172−173, suggesting that cocaine has the stronger hydrogen bonding with E196-301 compared to that with E172-173 in the TS1 structure. The enhanced hydrogen bonding helps to stabilize the transition-state (TS1) structure during the catalytic reaction process and, thus, lower the energy barrier, which explains the improved catalytic activity of the new mutant.

**In Vivo Protection of Mice against Cocaine-Induced Lethality.** For development of an effective cocaine abuse treatment using a cocaine-metabolizing enzyme, it is highly desired to have a long residence time of the enzyme in the body. To have a long residence time in the body, the enzyme must be thermostable at 37 °C for a sufficiently long time. So, it is a necessary condition, but not a sufficient condition, for an enzyme having a long residence time in the body to have a long *in vitro* half-life of the enzyme at 37 °C. An enzyme may be eliminated rapidly from the body, even if it is very thermostable at 37 °C. In this consideration, PEGylation is a popularly used strategy to prevent the possible rapid elimination of a protein from the body. Hence, we further engineered E196-301 through the PEGylation modification. Our activity assays confirmed that the PEGylated E196-301 completely maintained its activity against cocaine as that of E196-301.

To test the ability of E196−301 (unPEGylated, unless specified otherwise) and the PEGylated E196-301 in protecting mice (*n* = 5) from a lethal dose of cocaine, E196−301 or the PEGylated E196-301 was administered i.v. (at a single dose of 30 mg/kg) 1 min before the first i.p. administration of 180 mg/kg cocaine (LD100). Depicted in Figure 5 are the data for the *in vivo* protection of mice provided by E196−301 and the PEGylated E196−301 against the cocaine-induced lethality. As seen in Figure 5, E196−301 protected the mice from death after the first injection of 180 mg/kg cocaine, but lost the efficacy at the second injection of 180 mg/kg cocaine 24 h later. The PEGylated E196−301 was able to fully protect the mice (*n* = 5) for at least 72 h from the acute toxicity of a lethal dose of cocaine (180 mg/kg, LD100): no mouse died after the fourth cocaine challenge at 72 h, three mice died after the fifth cocaine challenge at 96 h, and the remaining two mice died after the

### Table 3. Summary of the MD-Simulated Key Distances (in Å) between the Hydrogen Atoms of Key Residue and the Carbonyl Oxygen of (−)-Cocaine Benzoyl Ester in the Rate-Determining Transition-State Structures of CocE

| hydrogen bond | distances (Å) | max. | min. | avg |
|---------------|--------------|------|------|-----|
| Y44HH−CocO⁶   | E172-173²⁷   | 3.02 | 1.44 | 1.87|
|               | E196-301⁷    | 3.17 | 1.44 | 1.80|
| Y114H−CocO⁸   | E172-173²⁷   | 3.14 | 1.61 | 2.16|
|               | E196-301⁷    | 2.89 | 1.61 | 2.13|

³E172-173 represents T172R/G173Q CocE, and E196-301 refers to T172R/G173Q/L196C/I301C CocE. ⁴Y44HH−CocO represents the distance between the hydroxyl hydrogen (denoted as HH) of the Y44 side chain and the carbonyl oxygen (denoted as CocO) of (−)-cocaine benzoyl ester. ⁵Y118H−CocO refers to the distance between the hydrogen (H) of the Y118 backbone and the carbonyl oxygen (CocO) of (−)-cocaine benzoyl ester.
The predicted cross-subunit disulfide bonds were expected to dramatically change the catalytic mechanism or significantly affect the transition bond lengths. The similar approximation was used in previously reported computational modeling studies on other esterases, leading to successful design and discovery of new mutants with a significantly improved catalytic activity.

The general procedure for carrying out the MD simulations in the present study was similar to that used in our previously reported computational studies. Briefly, all molecular mechanics-based energy minimization and MD simulations were carried out by using the AMBER 9 program package. The Amber force field (ff03) was used to establish the potentials of protein. For each system, counterions (Na⁺) were used to neutralize the system and, then, the neutralized system was immersed in an orthorhombic box of TIP3P water molecules with a minimum solute-wall distance of 10 Å. The whole system was carefully equilibrated and fully energy-minimized. After that, the system was gradually heated in the NPT ensemble from 0 K to 300 K and then equilibrated for 200 ps at 300 K. The production run was 20 ns (1 billion steps).

To analyze the catalytic efficiency, the kinetic parameters (v and Kₘ) were calculated by fitting the Lineweaver–Burk plots to a Michaelis–Menten equation. The catalytic efficiency (kcat/Kₘ) was calculated as the ratio of kcat to Kₘ. The experimental results were compared with the theoretical predictions made using the computational methods.
Site-Directed Mutagenesis. Point mutations were generated using the QuikChange method. Further mutations required to produce a new CocE mutant cDNA were generated from the cDNA corresponding to the E172−T73 in the pET-22b (+) bacterial expression vector. All mutants were sequenced in both directions over the entire coding region. Using plasmid DNA as template and primers with specific base-pair alterations, mutations were made by polymerase chain reaction with Pfu DNA polymerase for replication fidelity. The PCR product was treated with DpnI endonuclease to digest the parental DNA template. The digested product was transformed into Escherichia coli, amplified, and purified. The DNA sequences of the mutants were confirmed by DNA sequencing.

Protein Expression and Purification. The CocE mutants were expressed in Escherichia coli BL-21 (DE3) cells grown at 37 °C. Protein expression was induced with 1 mM isopropyl-β-D-thiogalactopyranoside (Sigma-Aldrich) for ∼15 h at 18 °C. Cells were pelleted, resuspended in 50 mM Tris-HCl, pH 8.0, 150 mM NaCl buffer with protease inhibitor cocktail (Sigma) and lysed using a French press (Thermo Fisher Scientific). The 6His-tagged enzymes were then enriched using HisPur cobalt resin (Thermo Fisher Scientific). The eluted fractions were concentrated by using an Amicon Ultra-50K centrifuge (Millipore, Billerica, MA). The enzyme concentrations were determined using a CB-Protein Assay kit (from CALBIOCHEM) with bovine serum albumin as a standard.

Enzyme Activity Assays. To measure (−)-cocaine and benzoic acid, the product of (−)-cocaine hydrolysis catalyzed by BChE, sensitive radiometric assays were used based on toluidine extraction of [3H]−(−)-cocaine labeled on its benzene ring. In brief, to initiate the enzymatic reaction, 100 nCi of [3H]−(−)-cocaine was mixed with the solution of the purified enzyme. The enzymatic reactions proceeded at 37 °C with varying concentrations of (−)-cocaine. The reactions were stopped by adding 200 μL of 0.1 M HCl, which neutralized the liberated benzoic acid whereas ensuring a positive charge on the residual (−)-cocaine. [3H]Benzoic acid was extracted by 1 mL of toluidine and measured by scintillation counting. Finally, the measured (−)-cocaine concentration-dependent radiometric data were analyzed by using the standard Michaelis-Menten kinetics with Prism 5 (GraphPad Software Inc., San Diego, CA).

To determine the in vitro half-life of the enzyme at 37 °C, the enzyme was diluted to 200 μg/mL, stored in sealed glass tubes and incubated at 37 °C. The tubes were sealed to avoid the possible vaporization-associated change in the volume. One tube will be taken out of the incubation cabinet at various time points (0, 2, 9, 12, 31, and 100 days) and assayed for the catalytic activity against (−)-cocaine as mentioned above. The percentage of remaining activity was plotted against the incubation time.

Crystallization and Structure Determination. Crystals of the designed new mutant of CocE were grown by hanging drop vapor diffusion, screening for conditions against the JCSG Core Suite (Qiagen). At a protein concentration of 10 mg mL−1 and 1:1 well-to-protein ratio, several screen conditions gave spindle-shaped or fusiform crystals. The most ordered crystals grew against wells containing 0.1 M phosphate-citrate (pH 4.2), 1.6 M sodium dihydrogen phosphate, and 0.4 M dipotassium hydrogen phosphate (JCSG IV # 94). The largest crystals were ∼0.2 mm in the longest dimension.

Crystals were mounted in Mylar loops (LithoLoops, Molecular Dimensions) and flash frozen44 in liquid nitrogen after passing for a few seconds through a solution containing the well solutes plus 20% glycerol. X-ray data were collected at beamline 22ID (SERCAT sector) at the Advanced Photon Source, Argonne National Laboratory at a temperature of 110 K. Data were reduced with the program HKL200045 and all aspects of structure determination and refinement were carried out in the Phenix suite. Initial phasing was done by molecular replacement (Phaser49 module) using the structure of unliganded cocaine esterase (PDB code 3I2J). Subsequent model refinement and addition of ordered solvent was carried out using the autobuild and refinement modules of Phenix with manual rebuilding in Coot50 which was also used to introduce the sequence changes into the model (T172R, G173Q, L196C, and I301C). Data reduction and model parameters are given in Table S1 of the Supporting Information.

PEGylation. Purified enzyme was conjugated with maleimide-linked branched poly(ethylene glycol) (PEG) with molecular weight of 40 kDa (JenKem Technology, Allen, TX) overnight in PBS buffer, pH 7.4 at the PEG to enzyme molar ratio of 20. The PEGylated protein was purified by using the same HisPur cobalt resin mentioned above.

In Vivo Studies. Male CD-1 mice (25−30 g) were purchased from Harlan (Indianapolis, IN) and were housed in groups of four mice per cage. All mice were allowed ad libitum access to food and water and were maintained on a 12 h light−dark cycle with lights on at 6:30 a.m. in a room kept at a temperature of 21−22 °C. Experiments were performed in accordance with the Guide for the Care and Use of Laboratory Animals as adopted and promulgated by the National Institutes of Health. The experimental protocols were approved by the Institutional Animal Care and Use Committee (IACUC) at the University of Kentucky.

The purified enzyme was administrated intravenously (i.v., via tail vein) and (−)-cocaine HCl (obtained from National Institute on Drug Abuse, Bethesda, MD) was administered intraperitoneally, at a volume of ∼0.2 mL/mouse. Cocaine-induced toxicity was characterized by the occurrence of lethality. Lethality was defined as cessation of observed movement and respiration. A single dose (30 mg/kg) of E196−301 with or without the PEGylation was administered intravenously (i.v.) 1 min before the first intraperitoneal (i.p.) administration of 180 mg/kg cocaine (n = 5). Then, the mice were challenged again daily with 180 mg/kg cocaine (i.p.) until no mouse survived. Following cocaine administration, mice were immediately placed individually for observation. The presence or absence of lethality was recorded for 60 min following cocaine administration.
