Abstract

MicroRNAs (miRNAs) are a group of small RNAs involved in various biological processes through negative regulation of mRNAs at the post-transcriptional level. Although miRNA profiles have been documented in over two dozen insect species, few are agricultural pests. In this study, both conserved and novel miRNAs in the diamondback moth, *Plutella xylostella* L., a devastating insect pest of cruciferous crops worldwide, were documented. High-throughput sequencing of a small RNA library constructed from a mixed life stages of *P. xylostella*, including eggs, 1st to 4th (last) instar larvae, pupae and adults, identified 384 miRNAs, of which 174 were *P. xylostella* specific. In addition, temporal expressions of 234 miRNAs at various developmental stages were investigated using a customized microarray analysis. Among the 91 differentially expressed miRNAs, qRT-PCR analysis was used to validate highly expressed miRNAs at each stage. The combined results not only systematically document miRNA profiles in an agriculturally important insect pest, but also provide molecular targets for future functional analysis and, ultimately, genetic-based pest control practice.

Introduction

MicroRNAs (miRNAs) are small (18–24 nucleotides, nt) genome-encoded non-coding RNAs (ncRNAs) and play crucial roles during the post-transcriptional gene expression in eukaryotes. By guiding the RNA-induced silencing complex (RISC) to bind to target “seed match” sites within the 3’ untranslated region (UTR) of mRNAs, miRNAs can suppress the translation of its target mRNA and hence silence its expression [1,2]. Evidence showed that some miRNAs can also suppress the expression of its target mRNA by binding to the 5’UTR [3] or open reading frame [4,5] of the mRNAs. It is estimated that though only 1% of the genomic transcripts in mammalian cells encode miRNA [6], nearly 50% of the encoded genes are regulated by miRNAs [7]. There is mounting evidence suggests that almost all known physiological and pathophysiological processes are negatively regulated by miRNAs, such as insect development (including cell development, wing development, muscle development, neurogenesis and cell apoptosis), host-pathogen interactions and immunity [8,9].

Since the first miRNA was discovered in *Caenorhabditis elegans* in 1993 [1,2], miRNAs have been identified in insects, vertebrates, plants and virus. To date, a total of 25141 mature miRNAs have been documented in 193 species, of which 25 species belong to the 6 insect orders, including Diptera (15 species), Hymenoptera (4 species), Homoptera (1 species), Lepidoptera (3 species), Coleoptera (1 species) and Orthoptera (1 species).

The diamondback moth, *Plutella xylostella* (L.), is a devastating lepidopteran pest of cruciferous crops worldwide, and the damage and management costs are estimated at $4–5 billion annually [10]. Extensive studies on the ecology and management of *P. xylostella* have been reviewed by Furlong, et al [11]. Recent transcriptome analyses and genome sequencing provide a unique opportunity to gain a molecular understanding of its adaptations to stressed environments [12–14]. Although Etebari, et al [15] identified a subset of miRNAs from the second instar larvae under parasitic stress; a comprehensive inventory of miRNAs in *P. xylostella* is lacking. In this study, conserved and novel miRNAs from all developmental stages in *P. xylostella* were inventoried systematically.

Materials and Methods

Ethics statement

*Plutella xylostella* strains used in this study were initially collected in Beijing in 2000, and have been maintained in our laboratory at the China Agricultural University for over 120 generations. No specific permit was required for the described field collections, and the location is not privately-owned or protected in any way. The species in the genus of *Plutella* are common agricultural pests and are not included in the “List of Endangered and Protected Animals in China”.

RNA isolation and sequencing

*Plutella xylostella* larvae and adults were reared at 27±1°C, 70±10% RH, and a 16:8 L: D photoperiod, as described previously [16]. Total RNA was isolated from the whole body homogenates of a sample mix, contained 50 mg of eggs, 1st to 4th
instar larvae, pupae and adults, respectively, using TRIzol reagent (Invitrogen, Carlsbad CA, USA) following the manufacturer’s instructions. Thirty five micrograms of total RNA were size-fractionated on a 15% TBE-Urea polyacrylamide gel. Small RNA populations of 18–28 nt were extracted, purified, and ligated to a 3′ linker and a 5′ linker using T4 RNA ligase (Ambion), and ligation products were used for SuperScript II reverse transcription (Invitrogen). PCR reactions were carried out using the RT primer and 5′ PCR primer. Linker and primer sequences are provided in additional file, Table S1. Amplified cDNA products were gel-purified and sent to BerryGenomics (Beijing) for high-throughput sequencing on an Illumina Hiseq2000.

### Bioinformatics analysis

A proprietary software package, ACGT101-miR v3.5 (LC Sciences, Huston, USA), was used for analyzing sequencing data generated. Reads with no matches to the proximal 11 nt of the 5′-adaptor were removed. Then the Reads mapped to the RepBase (v17, http://www.girinst.org) and Rfam (http://www.sanger.ac.uk/Software/Rfam/ftp.shtml) were removed before further analysis.

For the remaining unique sequences, various “mappings” were performed against pre-miRNA and mature miRNA sequences listed in the miRBase (v18, http://www.mirBase.org/) or B. mori genome (http://silkworm.genomics.org.cn/). First, unique sequences which mapped to insect pre-miRNAs in miRBase and

doi:10.1371/journal.pone.0078787.t002
potential miRNAs of *P. xylostella* mapped to known insect miRNAs, they were considered as potential miRNAs. The second structures of selected unique sequences un-mapped to insect pre-miRNAs but the pre-miRNAs did not map to the genome, if the unique sequences did not map to the *B. mori* genome and their extended sequences potentially formed hairpins, or if the unique sequences did not map to the *B. mori* genome but mapped to known insect miRNAs, they were considered as potential miRNAs of *P. xylostella*. The unique sequences unmapped to insect pre-miRNAs but mapped to *B. mori* genome and their extended sequences potentially formed hairpins were also considered as potential miRNAs. The second structures of selected pre-miRNAs were predicted by using RNAfold [17].

**μParaflo** TM miRNA microarray

To validate the predicted miRNAs, microarray was performed using a service provider (LC Sciences). The assay started from total RNA samples which were 3′-extended with a poly (A) tail using poly (A) polymerase. An oligonucleotide tag was then ligationed to the poly (A) tail for later fluorescent dye staining; two different tags were used for the two RNA samples in jual-sample experiments. Hybridization was performed overnight on a μParaflo microfluidic chip using a micro-circulation pump (Atactic Technologies) [18,19]. On the microfluidic chip, each detection probe consisted of a chemically modified nucleotide coding segment complementary to conserved or predicted novel *P. xylostella* miRNA and a spacer segment of polyethylene glycol to extend the coding segment away from the substrate. The detection probes were made by *in situ* synthesis using synthesis using PGR (photogenerated reagent) chemistry. The hybridization melting temperatures were balanced by chemical modifications of the detection probes. Hybridization used 100 μL 6×SSPE buffer (0.90M NaCl, 60 mM Na₂HPO₄, 6 mM EDTA, pH 6.8) containing 25% formamide at 34°C. After RNA hybridization, tag-conjugation Cy3 and Cy5 dyes were circulated through the microfluidic chip for dye staining. Fluorescence images were collected using a laser scanner (GenePix 4000B, Molecular Device) and digitized using Array-Pro image analysis software (Media Cybernetics). Data were analyzed by first subtracting the background and then normalizing the signals using a LOWESS filter (Locally-weighted Regression) [20]. For two color experiments, the ratio of the two sets of detected signals (log₂ transformed, balanced) and p-values of the t-test were calculated; differentially detected signals were those with less than 0.01 p-values. Hierarchical clustering was carried out using the TIGR MeV (MultiExperiment Viewer) v4.1 software, http://www.tm4.org/mev.html [21].

Quantitative RT-PCR

Twelve differently expressed miRNAs at various developmental stages were selected according to the initial microarray results and further verified using quantitative RT-PCR (qRT-PCR). Total RNA was extracted from 50 mg of eggs, 1° to 4° instar larvae, pupae and adults, respectively using TRIzol reagent as described previously. First strand cDNA was synthesized from 2 μg of total RNA using miScript II RT kit (Qiagen) following manufacturer’s instructions. The qRT-PCR reaction consisted of 1 μL of diluted cDNA, 10 μL of SYBR Green Master Mix (miScript SYBR Green PCR Kit, Qiagen, USA) and 1 μL of 10 μM of forward and reverse primer in 20 μL total volume. The forward primers were listed in table 1, and the universal reverse primer was supplied in miScript SYBR Green PCR Kit (Qiagen). The PCR reaction was conducted on an Applied Biosystems 7500HT Real-Time PCR System under the following conditions: 15 min template denaturation at 95°C, followed by 40 cycles of 94°C for 15 s, 55°C for 30 s, and 60°C for 30 s followed by the melting curve (68°C–95°C). Melting curves for each sample were analyzed after each run to check the specificity of amplifications. Three biological replicates with three technical replications were conducted for each qRT-PCR. A combination of three selected most stable miRNAs PN-isc-miR-276_R+1, PN-api-miR-9a_L+1 and PN-lmo-miR-279d_L-1117TC (unpublished data) were used as endogenous references for normalization (Table 1).

**Results**

**Predicted *P. xylostella* miRNAs using *B. mori* genome as a reference**

Solexa sequencing technology was used to identify miRNAs in the *P. xylostella*. A pooled small RNA library was constructed from the entire developmental stages of the insect (from eggs to adults). Sequencing yielded 4,620,660 reads, of which the reads without 3′ adaptor, or reads less than three copies or the length less than 15

Temporal expression of P. xylostella miRNAs at various developmental stages

The expression profiles of all 234 predicted miRNAs at various developmental stages were investigated using a customized microarray analysis. Among all the tested miRNAs, 143 miRNAs showed that more than 30% of miRNAs is 22 nt in length with the highest copy number (64.1%) among other miRNAs, and the miRNAs with 22–23 in length possessed more than 90% of reads. While the number of miRNAs with length 24–25 nt is less than 14.2% with even less copy number (<3.3%) (Table 3). According to the copy number, the five most abundant miRNAs were bmo-miR-1a, bmo-miR-8, bmo-miR-308, bmo-miR-100 and PN-bmo-miR-276*. A total of thirty three of most highly expressed miRNAs with copy number >1000 were listed in Table 4.
expressed evenly in eggs, larvae, pupae and adults, while the remaining 91 miRNAs were found differentially expressed at different developmental stages (Fig. S1). Of which nine miRNAs belong to four families, including miR-71, miR-11, miR-279 and miR-92, were highly expressed in eggs (Fig. 2A), and sixteen miRNAs from miR-1175, miR-750*, PC-3p-868, PC-5p-378, bmo-miR-282_L-3R-2, PN-dmo-miR-281_L-2R+24GA, PN-ami-miR-281_L-3R+3, bmo-miR-750_R+210TA, PN-bmo-miR-750_R+113C, PN-ami-miR-8_R+217TA, PN-isc-miR-8_R+1, PC-5p-3972, PC-5p-13964, PC-5p-3130, PC-5p-81253, bmo-miR-989_R+1, PN-dme-miR-277-3p_R+2 were highly expressed in pupae and adults, respectively (Fig. 2C, 2D). A total of 21 new miRNA candidates were identified and one of them (bmo-miR-989_R+1) was highly expressed in pupae and adults, respectively (Fig. 2C, 2D).

Figure 2. Microarray analysis of expression profiles of selected P. xylostella miRNAs at different developmental stages. After microarray hybridization and statistical analyses, a set of P. xylostella miRNAs differentially expressed in eggs, larvae, pupae and adults was identified. Two replicates and profiles clustering are presented for miRNAs significantly expressed among developmental stages. Microarray data were analyzed using the TIGR MeV (MultiExperiment Viewer) v4.1 software, http://www.tm4.org/mev.html, and one-way ANOVA. Color coding: red, up-regulated; black, mean; green, down-regulated. doi:10.1371/journal.pone.0078787.g002

other families showed a significantly higher expression level in larva stage but relatively lower expression level in eggs and pupae (Fig. 2B). There were four novel miRNA candidates (PC-5p-3972, PC-5p-13964, PC-5p-3130 and PC-5p-81253) and two miRNAs (bmo-miR-989_R+1 and PN-dme-miR-277-3p_R+2) were highly expressed in pupae and adults, respectively (Fig. 2C, 2D). A total...
of seven miRNAs were found highly expressed in both the eggs and the pupae, of which three miRNAs from miR-71 family and three from miR-2 family (Fig. 2E). In both pupae and adults, five miRNAs from both miR-210 and miR-307 families were found showed high expression level (Fig. 2F). There were six miRNAs increasingly expressed from eggs to adults, of which three belong to let-7 family and three miR-100 family (Fig. 2G).

To verify the microarray results described above, the relative expression levels of 12 differentially expressed miRNAs were further measured by qRT-PCR. Ten miRNAs showed similar expression patterns as those revealed by our microarray analysis.
For example, the microarray showed that PN-cqu-miR-279_21AT and bmo-miR-92b were highly expressed in eggs, and the results of qRT-PCR showed that these two miRNAs were exclusively high expressed in eggs with 5.1- and 8.2-fold higher than that in the fourth instar larvae, respectively (Fig. 3A, 3B). Similarly, the expression of bmo-miR-750_R+210TA in first to fourth instar larvae were 6.9- to 11.2-fold higher than that in eggs, and the expression of this miRNA in eggs showed no difference with that in pupae or adults (Fig. 3C). And the PC-5p-3130 and bmo-miR-989_R+1exclusively high expressed in pupae and adults respectively, and the expression level were 3.93- and 26.1-fold higher than that of in fourth instar larvae, respectively (Fig. 3D, 3E). While the PN-api-miR-2c-3p highly expressed in both eggs and pupae rather than in other stages (Fig. 3F), and both bmo-miR-210_L+1R+2 and bmo-miR-307_R+3 showed higher expression level in pupae (39.5- and 3.9-fold higher than that in 4th instar larvae) and adults (42.9- and 4.2-fold higher than that in 4th instar larvae) (Fig. 3G, 3H). Both the bmo-let-7_R+1 and bmo-miR-100 showed a increased expression from eggs to adults with significant difference in pupae and adults (Fig. 3I, 3J). The expression levels of miRNAs PN-bmo-miR-10*_R+1 and PN-aae-miR-87 detected by qRT-PCR inconsistent with that of the microarray results due to unknown reasons.

Predicted *P. xylostella* miRNAs using its own genome as a reference

Most recently, the genome sequences of *P. xylostella* was released [14], and subsequently the *P. xylostella* miRNAs were predicted again based on its own genome sequences (http://iae.fafu.edu.cn/DBM/download.php). After mapping to the *P. xylostella* genome and miRBase (2012 August Release 19, http://www.mirbase.org/) using a software package ACGT101-miR v4.2 (LC Sciences, Houston, USA), a total of 348 miRNAs were identified (Table 5, Table S2). The majority of these miRNAs were conserved across insects, in which 222 miRNAs were found in other insects, including 189 in *B. mori*. The remaining 126 miRNAs were considered *P. xylostella* specific and prefixed with “PC” in their names, indicating they could map to the genome of *P. xylostella* within hairpin but they are not homologous to any known insect miRNAs. To validate these predications, eleven miRNAs including 5 novel and 6 conserved, were subjected to qRT-PCR analysis (Table S3). All of the predicted miRNAs were amplified using a cDNA template extracted from the fourth instar larvae (Fig. 4).

Up to date, miRNAs have been indentified and studied in 25 insect species. *Plutella xylostella* miRNAs are highly homologous to those of *B. mori* and two other lepidopterans, *Manduca sexta* and *Heliconius melpomene* (Fig. 5). The most conserved region between *P. xylostella* pre-miRNA and other insects is the mature sequence and follows by the complementary sequence, whereas sequence far away from the mature region is highly varied. For example, mir-1a and mir-307 of *P. xylostella* showed very high identity to that of other insects, respectively, both at the mature and complementary regions (Fig S2, S3).

### Discussion

It has been demonstrated that miRNAs can affect almost all biological processes in insects [8]. The initial discovery of miRNAs in insects would lay the foundation for future functional characterization of these negative regulators. With the advent of the whole genome sequencing, miRNAs have been inventoried in 25 insect species including 12 *Drosophila* species [22], three

![Figure 4. Comparative analysis of miRNA sequence similarity between *P. xylostella* and other insect species.](http://www.plosone.org/)

As expected, *P. xylostella* miRNAs have the highest sequence similarity with Lepidoptera insects. doi:10.1371/journal.pone.0078787.g004

| miRNA Group | No. Unique miRNAs |
|-------------|-------------------|
| Known miRNAs |                     |
| of *P. xylostella* in miRBase | Group 1a | 0 |
| of other insects, but novel to *P. xylostella* | Group 1b | 31 |
| Predicted miRNAs |                     |
| Mapped to known pre-miRNAs of other insects and *P. xylostella* genome; within hairpins | Group 2a | 32 |
| Mapped to known pre-miRNAs of other insects and *P. xylostella* genome; no hairpins | Group 2b | 85 |
| Mapped to known pre-miRNAs and miRNAs of other insects but unmapped to *P. xylostella* genome | Group 3a | 70 |

| Unmapped to known miRNAs but mapped to *P. xylostella* genome and within hairpins | Group 4a | 126 |
| Total (Unique miRNAs) | | 348 |

Table 5. Known and predicted *P. xylostella* miRNAs referencing to its own genome. doi:10.1371/journal.pone.0078787.t005
mosquitoes (Anopheles gambiae, Aedes albopictus and Culex quinquefasciatus) [23,24], four hymenopterans (Aphis mellifera, Nasonia vitripennis, N. giraulti, and N. longicornis) [25,26], three lepidopterans (B. mori, M. sexta and Heliconius melpomene) [27–29], one coleopteran (T. castaneum) [30,31] and one hemipteran (Acyrthosiphon pisum) [32]. miRNAs in Locusta migratoria [33] and Blattella germanica [34] have also been documented. Most recently, miRNAs associated with parasitization by Diadegma semiclausum was reported in P. xylostella larvae [15]. These miRNAs were identified from the second instar larvae, and B. mori was used as a reference due to the lack of P. xylostella genome sequences.

In this study, a pooled small RNA library prepared from different development stages of P. xylostella (from eggs to adults) was sequenced. When using B. mori genome sequence as reference, a total of 234 miRNAs was identified, and when using the P. xylostella’s own genome data as reference, 348 miRNAs were identified, among which 120 miRNAs are overlapped. As a result, a total of 462 miRNAs were identified from various developmental stages in P. xylostella, of which 69 has been reported previously by Eeebari, et al [13]. 174 miRNAs from the remaining 383 novel miRNAs were P. xylostella specific. These combined results are the first step toward understanding the roles of miRNAs in P. xylostella metamorphosis, physiological and behavioral adaptations to the environment.

To provide a fine-tuning of target gene expression, information regarding the temporal and spatial expression profiles of miRNAs is essential [35]. In B. mori, the dynamics of miRNA expression profiles in different tissues and developmental stages have been resolved, respectively [26,36,38]. Here, the temporal expressions of P. xylostella miRNAs were investigated using a microarray analysis. Among the 234 miRNAs tested, 143 were expressed evenly in eggs, larvae, pupae and adults, while the remaining 91 were differentially expressed. For example, a total of nine miRNAs from four families (miR-71, miR-11, miR-279 and miR-92) were highly expressed in eggs, suggesting their specific functions in regulating the embryogenesis and metamorphosis of P. xylostella. It has been reported that miR-11 regulate the apoptosis during embryogenesis [39,40], while miR-279 determines olfactory neuron fate [40] in Drosophila. Similarly, miR-92 and miR-279 were found specifically expressed in the later embryos in B. mori [37]. During larval stage (from 1st to 4th instar), 16 miRNAs were significantly up-regulated, whereas, they were down-regulated in eggs and pupae, indicating that these miRNAs may be involved in the larva-pupa transition. In B. mori, miR-8 and miR-281 were also highly expressed at larval stage [37]. As a highly conserved miRNA, miR-8 is associated with the neurodegeneration, wingless signaling, growth control and neuromuscular junction development [41]. High expressions of four novel miRNAs (PC-5p-3972, PC-5p-13964, PC-5p-3130 and PC-5p-81253) in pupae suggested that they may play important roles in metamorphosis from pupae to adult, while bmo-miR-989_R+1 and PN-dme-miR-277-3p_R+2 may have specific functions in adults because of their significantly elevated expression levels in adults. Similar to B. mori, both let-7 and miR-100 were up-regulated and gradually accumulated from eggs to adults in P. xylostella.

In total, there are 16, 16, 16, and 7 P. xylostella miRNAs specifically expressed in eggs, larvae, pupae, and adults, respectively. Zhang, et al [36] found that 106 of 354 validated miRNAs were expressed in all stages of B. mori, while the remaining miRNAs were egg- and pupa-specific, suggesting that insect miRNAs play a significant role in embryogenesis and metamorphosis. Both microarray and qRT-PCR analyses have been used extensively to quantify miRNA expression. Results, however, are not always consistent. In this study, qRT-PCR analysis validated 10 out of 12 differentially expressed P. xylostella miRNAs identified by microarray analysis. Similarly, qRT-PCR analysis confirmed 6 out of 8 microarray-determined differentially expressed miRNAs in B. mori [36], suggesting that multiple tools, especially qRT-PCR analysis, should be used to accurately assess the expression level of miRNA.

Supporting Information

Figure S1 Microarray analysis of expression profiles of predicted P. xylostella miRNAs at different developmental stages. After microarray hybridization and statistical analyses, all detectable P. xylostella miRNAs differentially expressed in eggs, larvae, pupae and adults were subjected to one-way ANOVA at P = 0.01 and the hierarchical clustering using the TIGR MeV (MultiExperiment Viewer) v4.1 software, http://www.tm4.org/mev.html. Two replicates were performed. Color coding: red, up-regulated; black, mean; green, down-regulated. (TIF)
