(Dated: )

We investigate the spectrum of finite-length carbon nanotubes in the presence of onsite and nearest-neighbor superconducting pairing terms. A one-dimensional ladder-type lattice model is developed to explore the low-energy spectrum and the nature of the electronic states. We find that zero energy edge states can emerge in zigzag class carbon nanotubes as a combined effect of curvature-induced Dirac point shift and strong superconducting coupling between nearest-neighbor sites. The chiral symmetry of the system is exploited to define a winding number topological invariant. The associated topological phase diagram shows regions with nontrivial winding number in the plane of chemical potential and superconducting nearest-neighbor pair potential (relative to the onsite pair potential). A one-dimensional continuum model reveals the topological origin of the zero energy edge states: A bulk-edge correspondence is proven, which shows that the condition for nontrivial winding number and that for the emergence of edge states are identical. For armchair class nanotubes, the presence of edge states in the superconducting gap depends on the nanotube's boundary shape. For the minimal boundary condition, the emergence of the subgap states can also be deduced from the winding number.

I. INTRODUCTION

Single-wall carbon nanotubes (SWNTs) are one-dimensional (1D) crystals where the graphene honeycomb lattice, with its pseudospin valley degree of freedom, is rolled into a seamless cylinder. The finite curvature of the nanotube surface combined with the presence of valley and spin degrees of freedom is at the origin of a large variety of peculiar quantum transport properties, which have been intensively investigated in the last decades [1]. In recent studies, the emphasis has been put on the bound-state spectrum which naturally arises due to the finiteness of the SWNT length. It has been shown that the valley degeneracy of the bound states is not only lifted by the curvature-induced spin-orbit interaction [2–13], but also by a valley mixing from the edges [14, 15]. Furthermore, open-ended SWNTs commonly host edge states whose energies lie in the bulk band gap [14, 16, 17]. Topological considerations can give a new perspective on the nature of these localized states. Recently, a one-to-one correspondence has been shown between the number of edge states and a winding number topological invariant [18], and that a topological phase transition can be induced by an external magnetic field [19]. Although the topological argument does not give a detailed information on the edge states (e.g., on their decay length), the use of topological invariants enables a general discussion on the emergence of the edge states, which is possible as long as the corresponding bulk system keeps the band gap.

When a superconductor is connected to a normal conductor, superconducting correlations leak into the normal conductor [20] and can give rise to a proximity induced superconducting gap. In confined nanoconductors such as quantum dots and wires [21], resonant Andreev processes at the superconductor–normal-metal interface cause the formation of bound states with excitation energies below the superconducting gap, referred to as Andreev bound states. Such bound states have also been observed in SWNT-superconductor hybrid devices [22–27]. Reflecting superconducting correlations, the bound states correspond to entangled time-reversed electron-hole pairs and, hence, always come in pairs of opposite energy with respect to the center of the gap. Because the energy of the bound states depends on the microscopic details of the nanoconductor, in some systems it is possible to induce a crossing of the pair at zero energy upon variation of a gate voltage or of an external magnetic field [22, 24, 26]. Such states may like to stick at zero energy like a topological state, as pointed out in recent works on superconducting nanowires [28, 29]. In this context it is interesting to have the possibility to discriminate between nontopological bound states sticking at zero energy and truly topological zero energy bound states [30].

In this paper, we address theoretically the topological origin of zero energy bound states localized at the edges of a SWNT proximity coupled to a superconductor. On the one hand, we perform numerical calculations of the spectrum of SWNTs with length of a few micrometers which show that zero energy edge states emerge in some regions of chemical potential and proximity pairing strengths. These calculations are based on a 1D lattice model which includes the effects of curvature and superconductivity, and uses the helical-angular symmetry of the system [31]. It extends the 1D lattice model of Refs. [14, 18, 19] to the superconducting case. On the other hand, the chiral symmetry of the bulk Hamiltonian allows us to introduce a winding number as a topological invariant. We show that the edge states emerge in the parameter region of nontrivial, that is nonzero, winding number. The condition for the nontrivial wind-
The nontrivial winding number is the combined result of the curvature-induced shift of the Dirac points from the $K$ or $K'$ points, and strong superconducting coupling between nearest neighbors. Finally, a 1D continuum model is introduced which allows us to obtain the condition for the emergence of the edge states, which will be given in Eq. (43). By comparing with the previously obtained condition for a nontrivial winding number, we find that these conditions are identical, hence proving the bulk-edge correspondence in our system. We notice that the formation of edge states depends not only on the chemical potential and the pairing potentials, but also on the chirality and the boundary shape of the nanotubes since they strongly affect the coupling of the two valleys.

Since the zero energy bound states appear in the induced superconducting gap region, these states can be regarded as Andreev bound states. In contrast to the conventional Andreev bound states, which extend in the whole of the nanocoorder, the zero energy bound states we observe are more specifically regarded as surface Andreev bound states, which in our case are also of topological origin [30, 32].

Proximitized SWNTs in appropriately tuned magnetic or electric fields and with controlled gate voltage have been proposed as potential hosts of edge states of Majorana nature. Their formation relies on the spin-orbit coupling (either native [33], or induced by an electric field [34], a spiral magnetic field [35], or a nuclear spin helix [36]), as well as on breaking the time-reversal symmetry. In our model, we do not include an external magnetic field, thus the time-reversal symmetry is preserved and the edge states always appear in pairs. In agreement with a recent work [37], we find no edge states if only an onsite pairing is present. Also, no edge states appear as long as the onsite pairing is larger than the nearest-neighbor one. The inclusion of large nearest-neighbor pairings results in the appearance of edge states which, interestingly, are just Dirac fermions.

This paper is organized as follows. In Sec. II a formulation for superconducting SWNTs is given and the spectrum of the bulk system is presented. In Sec. III the numerically calculated edge states in the superconducting gap are shown and discussed. In Sec. IV the winding number is introduced as a 1D topological invariant and the topological phase diagram showing regions of nontrivial winding number is given. In Sec. V a 1D continuum model is analyzed to show the physics of the emergence of edge states and the bulk-edge correspondence is proven. In Sec. VI a case of strong valley coupling is studied on the example of the armchair class SWNTs. The conclusion is given in Sec. VII.

II. BOGOLIUBOV–DE GENNES HAMILTONIAN FOR FINITE-LENGTH SWNTS

A. Hamiltonian of a proximity-coupled SWNT

Let us consider a SWNT proximity coupled to a superconducting substrate [see Fig. 1(a)]. Proximity Hamiltonians have been investigated both in graphene [38, 39] and in SWNTs [40]. Following Ref. [38], we model the $\pi$ electrons in the SWNT in terms of a tight-binding Hamiltonian, which is given as the sum of a term $H_0$ describing the isolated system and of a term $H_{sc}$ accounting for proximity effects, $H = H_0 + H_{sc}$. For later purpose, we first discuss some key features of the term $H_0$ before turning to $H_{sc}$.

A SWNT is defined by rolling up a graphene sheet in the direction of the chiral vector $C_h = na_1 + ma_2$, where $a_1 = (\sqrt{3}/2, 1/2)a$ and $a_2 = (\sqrt{3}/2, -1/2)a$ are the unit vectors of graphene, $a = 0.246$ nm is the lattice constant, and the set of the two integers $(n, m)$ defines the geometrical structure, called chirality, of the SWNT [41] [see Fig. 1(b)]. The term $H_0$, which includes curvature-induced effects [19], is explicitly given as follows:

$$H_0 = -\mu_c \sum_{r\sigma s} c_{s\sigma r}^\dagger c_{s\sigma r} + \sum_{s} \sum_{j=1}^{3} \gamma_{s,j} c_{A r s}^\dagger c_{B r s+\delta_1} + H.c.$$  

where $c_{s\sigma r}$ is the annihilation operator of one electron on sublattice $\sigma (=A, B)$ at site $r$ and with spin $s = \pm 1$. 

\[ \delta_1 = (2) \delta \delta (s) + (1) \delta \delta (s) + (1) \delta \delta (s) + (2) \delta \delta (s) + (2) \delta \delta (s), \]   

where $c_{s\sigma r}$ is the annihilation operator of one electron on sublattice $\sigma (=A, B)$ at site $r$ and with spin $s = \pm 1$.
The spin quantization axis is chosen to be the nanotube axis. \( \mu \) sets the SWNT chemical potential and can be tuned, possibly, through external gate voltages. The vectors \( \delta_j^{(i)} (j = 1, 2, 3) \) point to the three nearest-neighbor B sites from the A site, and the vectors \( \delta_j^{(2)} (j = 1, \ldots, 6) \) point to the six next-nearest-neighbor sites [see Fig. 1(b)]. A spin-independent shift of the Dirac points is included in the nearest-neighbor hopping, while spin-orbit effects influence both the nearest-neighbor and next-nearest-neighbor hoppings. Reflecting the time-reversal symmetry we have \( (\gamma_{-s,j})^* = \gamma_{s,j} \). The explicit forms of the vectors \( \delta_j^{(i)} \) and the hopping integrals \( \gamma_{s,j} \) \( (t = 1, 2) \) are provided in Appendix A 1.

Regarding the effective pairing Hamiltonian \( H_{sc} \), we notice that the diameter \( d_0 \) of a SWNT is much smaller than a typical superconducting penetration length \( \lambda > 10 \text{ nm} \) [20]. Then, we can assume singlet superconducting pairing terms \( \Delta_0, \Delta_1 \) being constant on the whole lattice, yielding

\[
H_{sc} = \Delta_0 \left( \sum_{\sigma} c_{\sigma \uparrow}^\dagger c_{\sigma \downarrow} + \text{H.c.} \right) + \Delta_1 \sum_{\sigma} \sum_{j=1}^3 \left( c_{\text{Ar} \uparrow}^\dagger c_{\text{Br} \downarrow} + \delta_j^{(1)} \downarrow - c_{\text{Ar} \downarrow}^\dagger c_{\text{Br} \uparrow} + \delta_j^{(1)} \uparrow + \text{H.c.} \right).
\]

Here, we have alternatively used \( s = \uparrow, \downarrow \) for the spin index. The term proportional to \( \Delta_0 \) represents the onsite pairing, and the term proportional to \( \Delta_1 \) the pairing between the nearest-neighbor sites. The gauge freedom allows us to choose the coupling terms \( \Delta_0, \Delta_1 \) as real numbers. To determine the precise values of \( \Delta_0 \) and \( \Delta_1 \) for a given chirality of SWNT contacted to a superconducting substrate, a microscopic analysis of the interactions between the superconducting substrate and the SWNT would be needed [40], in principle including also pairing correlations between next-nearest and further neighbors. However, as will be shown below, the presence of nearest-neighbor pairing is the minimum requirement for the presence of nontrivial topological phases. Therefore in this paper we treat both \( \Delta_0 \) and \( \Delta_1 \) as parameters in order to study their interplay.

### B. The 1D lattice Hamiltonian in the helical-angular construction

Due to the \( C_d \) rotational symmetry of a SWNT with respect to the tube axis, the orbital angular momentum \( L_z = h \mu \) is a well-defined quantity, which is characterized by the integer,

\[
\mu = 0, 1, \ldots, d - 1.
\]

Here, \( d = \text{gcd}(n, m) \) is the greatest common divisor of \( n \) and \( m \). Note that the angular momenta \( \mu \) and \( \mu' \) are equivalent if \( \text{mod} (\mu - \mu', d) = 0 \), thus, e.g., \( \mu = -1 \) is equivalent to \( \mu = d - 1 \). Furthermore, also the spin component along the SWNT axis is a conserved quantity, which allows us to decompose the Hamiltonian into \( \mu \equiv (\mu, s) \) subspaces. The decomposition is performed by a partial Fourier transform in the circumference direction. To achieve this, it is convenient to use the helical-angular construction [18, 19, 31], in which the atomic position \( \mathbf{r} \) is expressed by the alternative unit vectors \( \mathbf{C}_h/d \) and \( \mathbf{H} \), where \( \mathbf{H} = p_a \mathbf{a}_1 + q_a \mathbf{a}_2 \) with the integers \( p_a \) and \( q_a \) satisfying \( m p_a - n q_a = d \). It holds \( \mathbf{r} = \nu (\mathbf{C}_h/d) + \ell \mathbf{H} + \delta_{\mathbf{h}}^{(1)} (\ell) \) with the two integers \( \nu = 0, 1, \ldots, d - 1 \) and \( \ell \). The integer \( \ell \) indicates the lattice position in the axis direction in units of \( a_s = \sqrt{3} a_0 / 2 \sqrt{2} a_s^2 + m^2 + n \), which is the shortest distance between \( \sigma \) atoms in the axis direction [see Fig. 1(b)]. In this framework, the two-dimensional (2D) wave vector is expressed as \( \mathbf{k} = \mu \mathbf{Q}_1/d + k \mathbf{Q}_2/(2\pi/a_z) \), where \( k \) is the wave number along the nanotube axis defined in the 1D Brillouin zone (BZ) \( - \pi / a_z \leq k < \pi / a_z \), and \( \mathbf{Q}_1 \) and \( \mathbf{Q}_2 \) are the two reciprocal lattice vectors conjugated to \( \mathbf{C}_h/d \) and \( \mathbf{H} \), respectively. That is, the relations \( \mathbf{Q}_1 \cdot \mathbf{C}_h/d = \mathbf{Q}_2 \cdot \mathbf{H} = 2\pi \) and \( \mathbf{Q}_1 \cdot \mathbf{H} = \mathbf{Q}_2 \cdot \mathbf{C}_h/d = 0 \) hold. Then, the partial Fourier transform is expressed as

\[
c_{\sigma \ell} = \frac{1}{\sqrt{d}} \sum_{\mu=0}^{d-1} \exp \left( \frac{2\pi i}{d} \nu \mu \right) c_{\sigma \ell \mu}.
\]

The Hamiltonian of the normal term is rewritten as \( H_0 = \sum_{\ell, \mu} H_{0,\ell,\mu} \), where \( 14, 18, 19, \)

\[
H_{0,\ell,\mu} = -\mu_c \sum_{\ell, \sigma} c_{\sigma \ell \mu}^\dagger c_{\sigma \ell \mu} + \sum_{\ell, j=1}^3 \epsilon_{\ell j}^{(1)}(1) \gamma_{s,j}^{(1)}(1) \mu_c c_{\text{Br} \ell j \mu} + \text{H.c.}
\]

\[
+ \sum_{\ell, j=1}^3 \epsilon_{\ell j}^{(2)}(2) \gamma_{s,j}^{(2)} c_{\sigma \ell \mu}^\dagger c_{\sigma \ell \mu} + \text{H.c.,}
\]

where

\[
\epsilon_{\ell j}^{(1)}(\ell) = \ell + \delta_{\ell j}^{(1)}, \quad t = 1, 2.
\]

The hopping distance \( \delta_{\ell j}^{(1)} \) and the phase factor \( \delta_{\ell j}^{(2)} \) are determined from \( \delta_{\ell j}^{(1)} = \delta_{\ell j}^{(1)} \mathbf{C}_h/d + \delta_{\ell j}^{(1)} \mathbf{H} \). Their explicit expressions are given in Table I. As schematically

| \( j \) | \( j = 1 \) | \( j = 2 \) | \( j = 3 \) | \( j = 4 \) | \( j = 5 \) | \( j = 6 \) |
|---|---|---|---|---|---|---|
| \( \delta_{\ell j}^{(1)} \) | \( \frac{n-m}{a} \) | \( \frac{2n+m}{a} \) | \( \frac{2n-m}{a} \) | \( \frac{2n-m}{a} \) | \( \frac{m}{a} \) | \( \frac{n}{a} \) |
| \( \delta_{\ell j}^{(2)} \) | \( \frac{m}{a} \sqrt{d} \) | \( \frac{n}{a} \sqrt{d} \) | \( \frac{n}{a} \sqrt{d} \) | \( \frac{m}{a} \sqrt{d} \) | \( \frac{n}{a} \sqrt{d} \) | \( \frac{n}{a} \sqrt{d} \) |

The hopping distance \( \delta_{\ell j}^{(1)} \) and phase factor \( \delta_{\ell j}^{(2)} \) in the 1D lattice model [18, 19]. The integers \( p_a \) and \( q_a \) satisfy \( m p_a - n q_a = d \), where \( d = \text{gcd}(n, m) \).
shown in Fig. 1(c), the Hamiltonian in each \( \mu \) subspace represents a ladder-type 1D lattice model [18, 19, 31]. Under the partial Fourier transform of Eq. (4), the superconducting term of the Hamiltonian takes the form,

\[
H_{sc} = \sum_{\mu} \left[ \frac{\Delta_0}{2} \sum_{\ell \sigma} s c_{\sigma \ell \mu}^\dagger c_{\sigma \ell - \mu} + H.c. \right. \\
\left. + \Delta_1 \sum_{\ell} \sum_{j=1}^{3} e^{i \frac{2\pi}{3} \delta \ell j (\mu)} s c_{A \ell \mu}^\dagger c_{B \ell j (\mu)}^\dagger + H.c. \right].
\]

(7)

The pair \( \mu \) and \(-\mu\) in the superconducting term reflects the conservation of angular momentum and spin.

C. Bogoliubov–de Gennes formalism for the 1D lattice Hamiltonian

Since the total Hamiltonian \( H_0 + H_{sc} \) has a bilinear form in the fermionic operators \( c_{\sigma \ell \mu} \), the excitation spectrum is conveniently calculated within the Bogoliubov–de Gennes (BdG) formalism [20]. The BdG Hamiltonian \( \mathcal{H} \) is given by doubling the fermionic operators upon introduction of the Nambu spinor

\[
c_{\sigma \ell \mu}^\dagger = \left( \begin{array}{c} c_{\sigma \ell \mu}^\dagger \end{array} \right), \quad \sigma_{\ell \mu} = \left( \begin{array}{c} c_{\sigma \ell \mu} \end{array} \right).
\]

(8)

For instance, the superconducting term proportional to \( \Delta_0 \) in Eq. (7) is rewritten as

\[
\Delta_0 \sum_{\ell} \sum_{j=1}^{3} e^{i \frac{2\pi}{3} \delta \ell j (\mu)} s c_{A \ell \mu}^\dagger c_{B \ell j (\mu)}^\dagger + H.c. = \Delta_0 \sum_{\ell} \sum_{j=1}^{3} e^{i \frac{2\pi}{3} \delta \ell j (\mu)} s c_{\sigma \ell \mu}^\dagger c_{\sigma \ell - \mu}. 
\]

(9)

D. Energy bands and BdG spectrum of the bulk system

Exploiting translational invariance, the BdG Hamiltonian of the bulk system is written in the Bloch basis as \( \mathcal{H}_\mu = \sum_{k} c_{k \mu} \mathcal{H} (k) c_{k \mu} \), where

\[
\mathcal{H} (k) = \left( \begin{array}{cc} \varepsilon_{c \mu} (k) & f_{c \mu} (k) \\ f_{c \mu}^* (k) & \varepsilon_{c \mu} (k) \end{array} \right) \hat{\pi}_z \\
+ s \left( \begin{array}{cc} \Delta_0 & f_{eh \mu} (k) \\ f_{eh \mu}^* (k) & \Delta_0 \end{array} \right) \hat{\pi}_x
\]

(11)

and

\[
f_{c \mu} (k) = \sum_{j=1}^{3} \gamma_{s,j}^{(1)} (1 + i k) \delta_{ij} (\mu), \quad f_{eh \mu} (k) = \Delta_1 \sum_{j=1}^{3} e^{i k} \delta_{ij} (\mu), \\
\varepsilon_{c \mu} (k) = - \mu_c + \varepsilon_{so \mu} (k), \quad \varepsilon_{so \mu} (k) = \sum_{j=1}^{6} \gamma_{s,j}^{(2)} e^{i k} \delta_{ij} (\mu).
\]

(12)

The Nambu spinor in \( k \) space is \( c_{k \mu} = c_{A k \mu}^\dagger c_{B k \mu}^\dagger c_{A - k - \mu} c_{B - k - \mu} \) with \( c_{so \mu} = \frac{i}{\sqrt{N}} \sum_{\ell} \exp (-i k \ell) \sigma_{\ell \mu} \), and \( k = (\mu, k) \). The BdG spectrum of the bulk system is obtained by diagonalizing the Hamiltonian matrix of Eq. (11).

1. Energy bands for the normal case

Before showing the BdG spectrum of the bulk system, we shall review the energy bands of the normal case. Until discussing the BdG spectrum, we set the chemical potential to be zero, \( \mu_c = 0 \). The conduction and the valence bands of the SWNTs are given by diagonalizing the matrix in the first term of Eq. (11) and have the standard form [1]

\[
\varepsilon_{\mu} (k) = \varepsilon_{so \mu} (k) \pm | f_{c \mu} (k) |,
\]

(13)

where the signs + and − correspond to the conduction and the valence bands, respectively.

It is well known that the SWNTs are metallic when \( \text{mod}(2n + m, 3) = 0 \) and semiconducting if \( \text{mod}(2n + m, 3) = 1, 2 \) [41]. Recent studies [14, 15, 18, 42] have revealed that the SWNTs can be alternatively classified into two classes according to the angular momentum of the two valleys, denoted in the following \( K \) and \( K' \): (i) zigzag class, which includes metal-1 (metallic SWNTs with \( d_R = d \)) and semiconducting SWNTs with \( d \geq 4 \), in which the two valleys have different angular momenta, where \( d_R = \text{gcd}(2n + m, 2m + n) \); (ii) armchair class, which includes metal-2 (metallic SWNTs with \( d_R = 3d \)) and semiconducting SWNTs with \( d \leq 2 \), in which the two valleys have the same angular momentum. Here
the angular momentum $\mu_\tau$ of valley $\tau (=K,K')$ is defined as follows. For the metallic SWNTs, $\mu_\tau$ is the angular momentum at the $\tau$ point, which is given by $\mu_\tau = \text{mod}[\tau(2n + m)/3,d]$ [18], where we have alternatively used $\tau = 1$ ($-1$) for the valley $K$ ($K'$). At the same time, the 1D wave number for the $\tau$ point is given by $k_\tau = (2\pi/3a_z)\text{mod}[\tau(2p + q),3]$ [18]. For the semiconducting SWNTs, the corresponding angular momenta and the 1D wave numbers are given by the ones which are closest to the $\tau$ point. Their explicit expressions are also given in Ref. [18].

Specifically, $\mu_K = \mu_{K'} = 0$ holds for the metal-2 SWNTs [14]. Figure 2 clearly shows the above features: in Fig. 2(a) we depict the energy bands of an $(n,m) = (6,3)$ SWNT which belongs to the zigzag class. The angular momentum $\mu_K = 2$ of valley $K$ is different from that of the $K'$ valley which is $\mu_{K'} = 1$. On the other hand, Fig. 2(b) shows the energy band of an $(n,m) = (8,2)$ SWNT, representative of the armchair class, where $\mu_K = \mu_{K'} = 0$.

Since we are focusing on the states near the $K$ and $K'$ valleys, it is sufficient to consider a limited number of $\mu$ subspaces, which are specified by the angular momenta of the valleys. In the following, we focus on the zigzag class SWNTs where two valleys are well decoupled. The armchair class will be discussed in Sec. VI.

2. BdG spectrum of zigzag class SWNTs

Since our interest is on the impact of superconductivity on the conducting electrons, the chemical potential will be set in the energy region corresponding to electron transport. Figure 3(a) shows the energy bands near the $K$ point for an $(n,m) = (6,3)$ SWNT. The dashed line indicates the chemical potential. Figure 3(b) shows the corresponding BdG spectrum. As shown in the two insets, the BdG spectrum exhibits small superconducting gaps of the order of the superconducting couplings near the two Fermi points $k = k^{(r)}_\tau$ and $k = k^{(r')}_{\tau'}(> k^{(r)}_\tau)$, at which

$$\mu_c = \varepsilon_{\mu_c}(k^{(r)}_\tau), \quad (r = \pm 1),$$

is satisfied in the $\tau$ valley, where $\tau \equiv (\tau,s)$, $\mu_{\tau} \equiv (\mu_{\tau},s)$, and $\varepsilon_{\mu_c}(k^{(r)}_\tau)$ is the single-particle energy of band $\mu_c$ at $k^{(r)}_\tau$ given by Eq. (13).

For a moderate chemical potential $|\mu_c| \lesssim 1$ eV, the $k \cdot p$ scheme can be used. The hopping functions $f_{c,\mu}$ and $f_{ch,\mu}$ are expanded around the $\tau$ point as [7]

$$f_{c,\mu}(k) \simeq c \gamma \left[(k_z - \tau \Delta k_c) + i (k_c - \Delta k_c,\tau)\right],$$

$$f_{ch,\mu}(k) \simeq c \Delta_1 (k_z + ik_c), \quad \varepsilon_{\mu_c}(k) \simeq -\mu_c,\tau,$$

where $c$ is a complex coefficient encoding the chiral angle and valley with $|c| = \sqrt{3d}/2$, and

$$\Delta k_c,\tau = \Delta k_c + \tau s \Delta k_{so}, \quad \mu_c,\tau = \mu_c - \tau s \varepsilon_{so}.$$

Here, $\Delta k_z$, $\Delta k_c$ are the curvature-induced shifts of the Dirac point from the $K$ point in the circumferential and the axial directions, respectively. $\Delta k_{so}$ and $\varepsilon_{so}$ are the spin-dependent Dirac point shift in the circumferential direction and the Zeeman-type energy shift, respectively, induced by the spin-orbit interaction. Their
explicit expressions are given in Eqs. (A4) and (A5) in Appendix A1. Finally, $k_z$ and $k_r$ are the wave numbers in the circumferential and axial directions measured from the $\tau$ point, and $k_c = 0, -2/3d_t$, and $2/3d_t$ for metallic, type-1 [mod$(2n + m, 3) = 1$], and type-2 [mod$(2n + m, 3) = 2$] semiconducting SWNTs, respectively. Using Eq. (15), the two Fermi points measured from the $\tau$ point are given by,

$$k^{(\tau)}_r = \tau \Delta k_z + r \sqrt{\left(\frac{\mu_c}{|c|\gamma}\right)^2 - (k_c - \Delta k_c, \tau)^2}.$$  \hspace{1cm} (17)

And, as shown in Appendix B, the superconducting gap near $k^{(\tau)}_r$ is expressed as

$$\varepsilon^{(\tau)}_{g,r} = 2\Delta_0 + 2\Delta_1 \left[ 1 + \varepsilon_{c,\tau} E_{c,\tau} \right] - r \tau \text{sgn}(\mu_c, \tau) \varepsilon_{z,\tau} \sqrt{1 - E^2_{c,\tau}},$$  \hspace{1cm} (18)

where

$$E_{c,\tau} = \frac{|c|\gamma (k_c - \Delta k_c, \tau)}{\mu_c, \tau}, \quad \varepsilon_{c,\tau} = \frac{|c|\gamma \Delta k_c, \tau}{\mu_c, \tau},$$

$$\varepsilon_{z,\tau} = \frac{|c|\gamma \Delta k_z}{\mu_c, \tau}.$$  \hspace{1cm} (19)

Since the absolute value of the numerator of $E_{c,\tau}$ expresses the half of the bulk band gap, the relation $|E_{c,\tau}| < 1$ holds when the chemical potential is in the energy band regions. It should be noted that the superconducting gaps at the two Fermi points $k^{(\tau)}_r (r = \pm)$ are different as shown in the inset of Fig. 3(b) as well as expressed in Eq. (18). This is because the contribution of $\Delta_1$ to the superconducting gap is $k$ dependent, as shown in Eq. (15), and the contribution at the two Fermi points is different, reflecting the shift $\Delta k_z$ of the Dirac point. The two different superconducting gaps at the two Fermi points play an important role in the emergence of edge states, as will be discussed later.

Next, we focus on the low-energy BdG excitations, of the order of the superconducting gaps, in finite-length SWNTs.

### III. BdG SPECTRUM IN FINITE-LENGTH SWNTS

We focus on an $(n,m) = (6,3)$ SWNT with $N_L = 2 \times 10^5$, which corresponds to a SWNT length of 16.1 $\mu$m, for the zigzag class SWNTs. The BdG Hamiltonian is diagonalized as

$$\mathcal{H}_\mu = \sum_{l_c} \varepsilon^{(\mu_l_c)}_{\text{BdG}} b^\dagger_{\mu_l_c} b_{\mu_l_c},$$  \hspace{1cm} (20)

where $l_c$ enumerates the quasiparticle energy levels, and

$$b^\dagger_{\mu_l_c} = \sum_{\ell} \left( \phi^{(\mu_l_c)}_{\mu,\sigma,\ell}(\ell) c^\dagger_{\sigma,\mu,\ell} + \phi^{(\mu_l_c)}_{\mu,\sigma,\ell}(\ell) c_{\sigma,\ell - \mu} \right).$$  \hspace{1cm} (21)

![Figure 4](image.png)

Figure 4 shows the calculated spectrum in the energy region of the order of the superconducting gaps in the subspace $\mu = (\mu_K = 2, 1)$. The boundary shape is depicted in Fig. 1(c), which belongs to the class of so-called minimal boundaries. The eigenvalue solver FEAST [43] of the Intel Math Kernel Library was used for the numerical calculation. The dashed lines show the evolution of the superconducting gaps $\varepsilon^{(\mu, \tau)}_{g, r}$ given in Eq. (18) with $\Delta_1$ [Fig. 4(a)] and $\mu_c$ [Fig. 4(b)]. The functions $\phi_{\chi, A}, \phi_{\xi, A}$ shown in the inset of Fig. 4(b) are connected to $\phi_{p, A}, \phi_{h, A}$ by a unitary transformation

$$\begin{pmatrix} \phi_{\chi, A} \\ \phi_{\xi, A} \end{pmatrix} = U_{\pi}^{-1} \begin{pmatrix} \phi_{p, A} \\ \phi_{h, A} \end{pmatrix},$$  \hspace{1cm} (22)

where

$$U_{\pi} = \frac{1}{2} \begin{pmatrix} 1 + i & 1 + i \\ 1 - i & 1 - i \end{pmatrix}.$$  \hspace{1cm} (23)

We will discuss this transformation in the next section. In the region $1.5 \lesssim \Delta_1 \lesssim 3$ meV in Fig. 4(a) and $400 \lesssim \mu_c \lesssim 900$ meV in Fig. 4(b), states near zero energy exist inside the gap region. As shown in the inset in Fig. 4(b), these states are localized at the edges and their nature will be discussed in the coming sections. Calculations for the other three subspaces, $(\mu_K, -1)$ and $(\mu_K, \pm 1)$, where $\mu_K = 1$, exhibit an almost identical behavior (not shown) as the one seen in Fig. 4. Emergence of the zero energy states in these region is also seen (not shown) for other boundary shapes, e.g., when removing or adding a A sublattice at the end of the boundary shown in Fig. 1(c).
The numerical result in Fig. 4 clearly shows that there exist edge states at zero energy in some parameter regions. To explore the condition for the emergence of the edge states, we will analyze the bulk system from a topological viewpoint.

IV. WINDING NUMBER

Let us again consider the bulk Hamiltonian given in Eq. (11). Since the Hamiltonian has the chiral symmetry \( \{ \Gamma, \mathcal{H}_\mu \} = 0 \), where \( \Gamma = \pi_y \), one can introduce the winding number

\[
w_\mu = -\frac{1}{4\pi i} \int_{-\pi/a_{\mu}}^{\pi/a_{\mu}} dk \text{Tr} \left[ \Gamma \mathcal{H}_\mu^{-1}(k) \partial_k \mathcal{H}_\mu(k) \right]
\]

(24)
as a 1D topological invariant [44, 45]. The identity with another definition of the winding number, which uses a flat band Hamiltonian [46], is proven in Appendix C.1.

Let us consider the unitary transformation \( U_\pi \) defined in Eq. (23), which rotates the Pauli matrices for the particle-hole basis as \( U_\pi^\dagger \tilde{\pi}_Z U_\pi = \tilde{\pi}_x \), \( U_\pi^\dagger \tilde{\pi}_Y U_\pi = \tilde{\pi}_z \), \( U_\pi^\dagger \tilde{\pi}_Z U_\pi = \tilde{\pi}_x \). Correspondingly, the Hamiltonian in Eq. (11) takes in the following an off-diagonal form,

\[
\tilde{\mathcal{H}}_\mu(k) = U_\pi^\dagger \mathcal{H}_\mu(k) U_\pi = \begin{pmatrix} 0 & h_\mu(k) \nu \pi \mu

h_\mu(k) \nu \pi \mu

0 \end{pmatrix},
\]

(25)

where

\[
h_\mu(k) = \begin{pmatrix} \varepsilon_{c,\mu}(k) - i s \Delta_0 & f_{c,\mu}(k) - i s f_{eh,\mu}(k) \\

f_{c,\mu}^*(k) - i s f_{eh,\mu}(k) & \varepsilon_{c,\mu}(k) - i s \Delta_0
\end{pmatrix}.
\]

(26)

At the same time, the fermionic operators are transformed as

\[
\begin{pmatrix} \varepsilon_{c,\mu} \nu \pi \mu \\

\varepsilon_{c,\mu} \nu \pi \mu
\end{pmatrix} \equiv U_\pi^{-1} \begin{pmatrix} \varepsilon_{c,\mu} \nu \pi \mu \\

\varepsilon_{c,\mu} \nu \pi \mu
\end{pmatrix}.
\]

(27)

Because the chiral operator is transformed as \( \tilde{\Gamma} = U_\pi^\dagger \Gamma U_\pi = \pi_z \), the winding number is written as

\[
w_\mu = \frac{1}{2\pi} \int_{-\pi/a_{\mu}}^{\pi/a_{\mu}} dk \partial_k \arg \det h_\mu(k),
\]

(28)

with the determinant of \( h_\mu(k) \) being

\[
\det h_\mu = \varepsilon_{c,\mu}^2 - \Delta_0^2 - |f_{c,\mu}|^2 + |f_{eh,\mu}|^2 \\
+ 2 i s \left( \varepsilon_{c,\mu} \Delta_0 - f_{c,\mu}^* f_{eh,\mu} + f_{c,\mu} f_{eh,\mu}^* \right)
\]

(29)

(see Appendix C.2 for the derivation).

For the case of \( |\Delta_0|, |\Delta_1| \ll |\varepsilon_c|, |\gamma| \), on which we are focusing, the real part of \( \det h_\mu \) is expressed as

\[
\text{Re} (\det h_\mu) \simeq \varepsilon_{c,\mu}^2 - |f_{c,\mu}|^2 \\
= [-\mu_c + \varepsilon_{so,\mu}]^2 - |f_{c,\mu}|^2.
\]

(30)

Except near the Fermi points, we have

\[
|\text{Re} (\det h_\mu)| \gg |\text{Im} (\det h_\mu)|
\]

(31)
since the imaginary part of \( \det h_\mu \) is proportional to the superconducting pairing potentials \( \Delta_0 \) and \( \Delta_1 \). Therefore, Eq. (29) is approximated as a positive or negative real number, and then the phase of \( \det h_\mu \) is almost constant and equal to 0 or \( \pi \). This feature is clearly observed in Fig. 5, which shows the phase of the determinant of \( h_{(\nu \pi \mu)} \) near the K point.

Let us focus on the regions near the Fermi points at the \( \tau \) valley, which are the only ones where the phase of \( \det h_{\nu \pi \mu} \) changes and a finite contribution to the integral in Eq. (28) is expected, as can be seen in Fig. 5. As seen in the \( \mathbf{k} \cdot \mathbf{p} \) scheme, in which the functions \( f_{c,\mu} \) and \( f_{eh,\mu} \) have the form in Eq. (15), \( \text{Re} (\det h_{\nu \pi \mu}) \) behaves quadratically in \( k \) near the \( \tau \) point. That is, \( \text{Re} (\det h_{\nu \pi \mu}) \) is positive for \( k_z < k_{\nu \pi \mu} \) and \( k_z > k_{\nu \pi \mu} \), and is negative for \( k_{\nu \pi \mu} < k_z < k_{\nu \pi \mu} \). Note that the two roots of \( \text{Re} (\det h_{\nu \pi \mu}) \) are regarded as the two Fermi points in our approximation of small superconducting couplings.

Let us define \( h_{\nu \pi \mu}^{(\tau)} \equiv h_{\nu \pi \mu}(k_{\nu \pi \mu}^{(\tau)}) \), the function \( h_{\nu \pi \mu} \) at the Fermi point for the \( \tau \) valley. When \( \text{Im} (\det h_{\nu \pi \mu}^{(\tau)}) \) has the opposite sign of \( \text{Im} (\det h_{\nu \pi \mu}^{(\tau)}) \),

\[
\text{Im} (\det h_{\nu \pi \mu}^{(\tau)}) \text{ Im} (\det h_{\nu \pi \mu}^{(\tau)}) < 0,
\]

(32)
then \( \det h_{\nu \pi \mu} \) near the Dirac point contributes to a nontrivial winding number (see the schematics in Fig. 6). Note that the maximum contribution to the winding number per Dirac point is \( |w_{\nu \pi \mu}| = 1 \) because of the above discussion. The sign of the winding number is given by the sign of \( \text{Im} (\det h_{\nu \pi \mu}^{(\tau)}) \), that is, the winding number is

\[
w_{\nu \pi \mu} = \text{sgn} (\text{Im} (\det h_{\nu \pi \mu}^{(\tau)})) |w_{\nu \pi \mu}|.
\]

(33)
Figure 7 shows the topological phase diagram for an \((n, m) = (6, 3)\) nanotube calculated from Eq. (32) for \((\tau, s) = (1, 1)\).

Within the \(k \cdot p\) approximation, after some algebra given in Appendix C 2, the condition (32) is summarized as

\[
\left[ \frac{\gamma}{\mu_{c, \tau}} + \left( \frac{\Delta_1}{\Delta_0} \right) \left( 1 + \varepsilon_{c, \tau} E_{c, \tau} \right) \right]^2 - \varepsilon_{z, \tau}^2 \left( \frac{\Delta_1}{\Delta_0} \right)^2 \left( 1 - E_{c, \tau}^2 \right) < 0. \tag{34}
\]

Using the relation

\[
\text{Im} \left( \det h^{(\tau)} \right) = s \mu_{c, \tau} \varepsilon^{(\tau)}_{g, r}, \tag{35}
\]

which is given in Appendix B [after Eq. (B18)], the sign of the winding number can also be evaluated. As seen in Eq. (34), the condition holds only when \(\varepsilon_{z, \tau} \neq 0\), that is, \(\Delta k_{z} \neq 0\), the case of a finite shift of the Dirac point in the axial direction, and \(\Delta_1 \neq 0\). Note that \(E_{c, \tau}^2 < 1\) holds outside the energy gap of the nanotubes. As shown in Eq. (A4), we have a finite \(\Delta k_{z}\) except for the pure zigzag SWNTs, for which the chiral angle is \(\theta = 0\). We also notice that the condition (34) depends on the ratio of \(\Delta_0\) and \(\Delta_1\) but not on their absolute values.

At the border, one of the two superconducting gaps \(\varepsilon^{(\tau)}_{g, r} (r = \pm)\) becomes zero. Then, from the condition \(\varepsilon^{(\tau)}_{g, r} = 0\) and Eq. (18), the border is determined by

\[
\frac{\Delta_1}{\Delta_0} = \frac{\gamma}{\mu_{c, \tau}} \left( 1 + \varepsilon_{c, \tau} E_{c, \tau} \right) + \tau \tau \text{sgn}(\mu_{c, \tau}) \sqrt{\varepsilon_{z, \tau}^2 \left( 1 - E_{c, \tau}^2 \right)} \frac{\varepsilon_{z, \tau}^2 \left( 1 - E_{c, \tau}^2 \right)}{(1 + \varepsilon_{c, \tau} E_{c, \tau})^2 - \varepsilon_{z, \tau}^2 \left( 1 - E_{c, \tau}^2 \right)}. \tag{36}
\]

Note that the border is also given by the roots of the left-hand side of Eq. (34). By comparing with the numerical calculation in Fig. 4, we confirm that the zero energy edge states appear in the region where the winding number has a nonzero value. The region becomes narrower and the borders asymptotically behave as \(\Delta_1/\Delta_0 \simeq -\gamma/\mu_{c}\) for a large \(\mu_{c}\). This implies that to have nontrivial winding number, the ratio \(\delta = \Delta_1/\Delta_0\) becomes smaller and comparable to 1 for \(|\mu_{c}| \sim |\gamma|\), as shown in Fig. 7. However, such a chemical potential might be unrealistically large.

Let us comment on the effect of the spin-orbit interaction. As shown in Eq. (16), the spin-orbit interaction gives the spin dependence in the phase diagram. Since we are focusing on the conducting region for the normal state, we have \(|\mu_{c}| \gg |\varepsilon_{so}|\). Furthermore, we also have the relation \(|\Delta k_{c}| \gg |\Delta k_{so}|\) except for the armchair SWNTs. For the armchair SWNTs, the spin-orbit interaction opens a small gap at \(\mu_{c} = 0\), as already pointed out in previous studies [2–4, 7]. Therefore, we have an almost identical phase diagram for the \((\tau, s)\) and \((\tau, -s)\) subspaces except for the sign difference reflecting the opposite winding direction between \(s\) and \(-s\), as seen in the relation (35). A small difference between the opposite spins, shown as the finite value of \(w_{|\mu_{K}|, 1} + w_{|\mu_{K}|, -1}\) in the inset of Fig. 7, appears at the border region scaled by the spin-orbit interaction. Note that the phase diagrams for \((\tau, s)\) and \((-\tau, -s)\) are the
same including the sign. Therefore, the total winding number, \( \sum_{r,s} w_{\mu r} = 2(w_{\mu(k_1,1)} + w_{\mu(k_1,-1)}) \), shows the same diagram as \( w_{\mu(k_1,1)} + w_{\mu(k_1,-1)} \). As a result, the total winding number is nonzero only in very narrow regions of the parameter space. Nevertheless, several edge states are present in the nanotube even when the total winding number is zero, which proves that the total topological invariant may miss a rich part of the physics of the system.

As a further example, it should be noted that in the armchair class, with \( \mu_k = 0 = \mu k \), the winding number \( w_{\mu} \) becomes zero even when the condition (34) is satisfied for both valleys. This is because the winding directions for the \( \tau \) and \( -\tau \) valley are opposite, which can be seen from the relation Eq. (35). However, this does not mean that there is no edge state for the armchair class, as will be discussed in Sec. VI.

Let us comment on the symmetry class to which our 1D model belongs according to the topological classification in Ref. [46]. Since we have only the chiral symmetry in each \( \mu \) subspace, the 1D model in that space belongs to the AIII class. The total Hamiltonian has time-reversal symmetry, and belongs to class DIII. Further discussion on the different topological invariants in our system can be found in Appendix C3.

It should be noted that the nontrivial topological phase obtained in our work does not contradict a previous study [37], which predicts only a trivial topological phase if the induced superconducting correlation is \( s \) wave. This correlation appears in our Hamiltonian as the onsite pairing. As already mentioned, the \( \Delta_1 \) term, which is the coupling constant for the \( k \)-linear term in Eq. (15), and thus acts as the \( p \)-wave superconducting coupling [38], is needed to have the nontrivial topological phases.

\section{V. BULK-EDGE CORRESPONDENCE}

In this section we shall reveal the deep physical meaning of the condition constituting Eq. (32). As mentioned in the Introduction, it has been shown [18] for the SWNTs in the normal state that the winding number per \( \mu \) space \( w_{\mu} \) is equal to the number of edge states in this space. The latter are given by the difference between the number of evanescent modes, being the solutions of the mode equation at zero energy, and the number of boundary conditions for given sublattice. This gives a one-to-one correspondence between the winding number as a topological invariant and the physical edge state. This kind of relation is called a bulk-edge correspondence. Let us discuss the bulk-edge correspondence for the present system by including the finite length of the SWNT in our description.

Since the relevant contribution to the winding number comes from the neighborhood of the \( \tau \) point, we shall consider an effective 1D continuum model obtained by expanding around the \( \tau \) point. The envelope function,

\[ \Psi_{\tau} = \begin{pmatrix} \Psi_{\chi \tau} \\ \Psi_{\xi \tau} \end{pmatrix}, \quad \Psi_{p\tau} = \begin{pmatrix} \Psi_{p\chi \tau} \\ \Psi_{p\xi \tau} \end{pmatrix}, \] (37)

obeys the equation,

\[ \hat{\mathbb{H}}_{\mu \tau}(\hat{k}_z)\Psi_{\tau} = \varepsilon \Psi_{\tau}, \] (38)

where \( p = \chi, \xi, \) and \( \hat{\mathbb{H}}_{\mu \tau}(\hat{k}_z) \) has the same functional form of Eq. (25) with Eq. (15). However, the wave number \( k_z \) is now regarded as the operator

\[ \hat{k}_z = -i \frac{\partial}{\partial z}, \] (39)

in the continuum model. At zero energy, \( \varepsilon = 0 \), the equation can be divided into two sets of equations with 2 \( \times \) 2 matrix forms:

\[ \hat{h}_{p\mu \tau}(\hat{k}_z)\Psi_{p\tau} = 0, \] (40)

where \( \hat{h}_{\chi \mu \tau}(\hat{k}_z) \) and \( \hat{h}_{\xi \mu \tau}(\hat{k}_z) \) are given by changing \( k_z \rightarrow \hat{k}_z \) in \( h_{\chi \mu}(k_z) \) and \( h_{\xi \mu}(k_z) \), respectively. Let us consider the modes with the following form:

\[ \Psi_{p\tau} = e^{i\eta z} \begin{pmatrix} 1 \\ \eta_p \end{pmatrix}. \] (41)

In each \( p \) block, the modes obey the following equation:

\[ \begin{pmatrix} -\mu_{c,\tau} + ips\Delta_0 \\ c [\gamma (q - \tau \Delta k_z) + ips \Delta_1 q] + c [i\gamma (k_z - \Delta k_{c,\tau}) - ps \Delta_1 k_z] - \mu_{c,\tau} + ips\Delta_0 \end{pmatrix} \begin{pmatrix} 1 \\ \eta_p \end{pmatrix} = 0, \] (42)

shown in Eq. (44).

Within the continuum model, the microscopic boundary condition is implicitly taken into account in order to form eigenstates. They are constructed as linear combinations of two independent modes, a leftgoing and a rightgoing one, subject to boundary conditions at each
end. Note that in the superconducting gap region the two modes are two decaying modes, that is, $|\kappa^{(\tau)}_+| < 1$ or $|\kappa^{(\tau)}_-| > 1$, where $\kappa^\tau = \text{Im}(q^\tau)$. If the two modes have the same decaying direction, that is,

$$\kappa^{+\tau} \kappa^{+\tau}_- > 0,$$

then an edge state given by the linear combination of the two modes appears at an end. In the following we explicitly show that this condition is identical to the condition (32) for nontrivial winding number.

As shown in Appendix D, we arrive after some algebra to the two solutions

$$\text{Re} (q^\tau) \simeq k^\tau, \quad \kappa^\tau \simeq \frac{r p s \text{sgn}(\mu_\ell, r) \Theta^\tau}{|c| \gamma \sqrt{1 - E^2_{\ell, r}}}. \quad (44)$$

Since we have the relation (35), we get

$$\kappa^\tau_r = \frac{r p \text{Im} (\det h^\tau_r)}{4 |\mu_{\ell, r}| |c| \gamma \sqrt{1 - E^2_{\ell, r}}}. \quad (45)$$

Combining Eqs. (43) and (45), it is immediately clear that the condition for emergence of an edge state is identical to the condition for a nontrivial winding number expressed by Eq. (32).

It is worth noting that, from Eq. (44), the decay length of the edge state is proportional to the Fermi velocity, $-|c| \gamma \sqrt{1 - E^2_{\ell, r}} / \hbar$, of the normal states at the given chemical potential and is inversely proportional to the superconducting gap. This implies the shortest decay length to be near the bottom of the conduction or top of the valence bands for the semiconducting SWNTs.

VI. ARMCHAIR CLASS

So far, we have been restricting ourselves to the case of decoupled valleys. Let us discuss the effect of valley coupling by considering the armchair class SWNTs, in which the two valleys have the same angular momentum.

In previous studies [14, 15], it has been shown that the nature of the valley coupling depends on the boundary conditions. Here we consider two types of boundaries. One is the minimal boundary, in which the edge has minimum number of dangling bonds [see Figs. 8(a) and 8(b)]. Another is the orthogonal boundary formed by a simple cut of the lattice in the plane orthogonal to the nanotube axis [see Figs. 8(a) and 8(c)]. The two valleys are nearly decoupled for the former case, while they strongly couple for the latter case, where each eigenstate is formed from a leftgoing mode at one valley and a rightgoing mode at another valley [14].

Figure 8 shows the calculated spectrum for an $(n, m) = (5, 2)$ nanotube with $N_L = 4 \times 10^5$, which corresponds to the nanotube length of 13.6 $\mu$m, in the subspace of $\mu = (\mu_K, 1)$, where $\mu_K = \mu_{K'} = 0$. Figures 8(d) and 8(e), which show the case of the minimal boundary, exhibit a spectrum similar to that in Fig. 4. Edge states near zero energy are seen inside the gap region for $1 \lesssim \Delta_1 \lesssim 4$ meV in Fig. 8(d), and for $350 \lesssim \mu \lesssim 950$ meV in Fig. 8(e). A small deviation from zero energy is observed because of weak valley coupling. On the other hand, Figs. 8(f) and 8(g), which show the case of the orthogonal boundary, do not support zero energy states in the same

$$\begin{array}{c}
\text{FIG. 8. BdG spectrum of an armchair class (5, 2) nanotube with length of 13.6 } \mu\text{m in the } \mu = (\mu, s) = (\mu_K, 1) \text{ subspace. (a) Unrolled tube near the left end. The boundary is formed by a simple cut of the lattice in the plane orthogonal to the nanotube axis, represented by the solid line perpendicular to the } z \text{ axis. Removed lattice sites adjacent to the boundary sites are represented by dashed circles, and the dangling bonds are represented by the dashed lines. The orthogonal boundary is given by keeping the Klein site indicated by K}_L, \text{ and the minimal boundary is given by removing the Klein site. (b) Minimal and (c) orthogonal boundaries, respectively, for the minimal boundary, and, (d) that as a function of the chemical potential } \mu, \text{ respectively, for the minimal boundary, and, (f) and (g) show those for the orthogonal boundary. Each inset in (e) and (g) shows the real part components } \phi_A \text{ (blue) and } \phi_A \text{ (red) in arbitrary units as a function of lattice site } \ell \text{ for the calculated eigenfunction at the state indicated by the red arrow. }
\end{array}$$
region of superconducting pairing and chemical potential as in Figs. 8(d) and 8(e). This is in contrast to the zigzag class SWNTs, in which the shape of the boundary does not affect the number of edge states if $\mu$ remains a good quantum number since the two valleys have different $\mu$ and they are decoupled.

The absence of zero energy states for the case of strong valley coupling in Figs. 8(f) and 8(g) can be captured by the expressions we have obtained in Sec. V. Between the two states specified by $(\tau, s, r)$ and $(-\tau, s, -r)$, which form a pair for an eigenstate under the boundary condition, we always have the relation $\kappa^{(\tau, s)} \sim -\kappa^{(-\tau, s)}$ because $\varepsilon^{(\tau, s)} \sim \varepsilon^{(-\tau, s)}$. Therefore, the condition (43) of emergence of edge states is never satisfied for this case.

VII. DISCUSSION AND CONCLUSION

We have studied the edge states in the proximity-induced superconducting gap of finite-length SWNTs from the topological viewpoint. Our analysis shows that the numerically observed edge states are due to the combined effect of curvature-induced Dirac point shifting and strong superconducting coupling between nearest-neighbor sites. A 1D continuum model reveals that the condition for nontrivial winding number coincides with the condition for emergence of edge states in the finite length case.

We have seen that in our setup the edge states of zigzag and armchair classes with the minimal boundary are formed not by time-reversal symmetric partners, but by the $(\tau, s, r)$ and $(\tau, s, -r)$ states. Here, $\tau$ is the index of the two valleys $K$ and $K'$, $s$ is that of spin direction $\uparrow$ and $\downarrow$, and $r$ is that of left and right branch of the energy bands. In armchair class with the orthogonal boundary it was impossible to construct an edge mode, because that required combining $(\tau, s, r)$ and $(-\tau, s, -r)$ states, which always decay in the opposite directions.

The zero energy edge states studied in this paper appear in pairs because of the unbroken time-reversal symmetry as well as the decoupling of two valleys. As seen in Fig. 8, mixings of subspaces such as spin mixing induced, e.g., by an external magnetic field or valley mixing induced, e.g., by broken rotational symmetry would couple the two pair members and they would deviate from the zero energy. These properties would be in contrast to those of the Majorana bound states, which emerge under breaking of the time-reversal symmetry and might further necessitate valley mixing, as shown, e.g., in the previous study [33]. Therefore, the control of the magnetic field as well as the rotational symmetry provides us with a tool for discriminating between the zero energy edge states discussed in this paper and the Majorana bound states.

Finally, it is interesting to comment on the possibility of Majorana bound states in the SWNTs. If the parameters of the system can be tuned in such a way that the bound states combine two time-reversal partners $(\tau, s, r)$ and $(-\tau, s, -r)$, the requirement of the same decay direction $\kappa^r\kappa^{-r} > 0$ follows automatically from Eq. (44). This can be achieved in the presence of the spin-orbit splitting could provide an odd number of time-reversal symmetric pairs. As discussed in Refs. [33, 35], the combined time-reversal symmetric partners may form edge states of Majorana nature.

Appendix A: Tight-binding Hamiltonian

Here we show the details of the tight-binding Hamiltonian.

1. Tight-binding Hamiltonian of the normal term

Here, we give the explicit form of the vectors $\delta^{(i)}_{s,j}$ and the hopping integrals $\gamma^{(i)}_{s,j}$ which appear in the standard term $H_0$ of the Hamiltonian in Eq. (1):

$$H_0 = -\mu c \sum_{\tau \sigma s} c^\dagger_{\tau \sigma s} c_{\sigma r s}$$

$$+ \sum_{\tau \sigma s} \sum_{j=1}^3 \gamma^{(1)}_{s,j} c^\dagger_{\tau \sigma s} c_{\sigma r + A \delta^{(1)}_{s,j}} + \text{H.c.}$$

$$+ \sum_{\tau \sigma s} \sum_{j=1}^3 \gamma^{(2)}_{s,j} c^\dagger_{\sigma r s} c_{\sigma r + \delta^{(2)}_{s,j}} + \text{H.c.}$$  \hspace{1cm} (A1)

The vectors to the three nearest-neighbor B sites from the A site are given by $\delta^{(1)}_1 = (a_1 + a_2)/3$, $\delta^{(1)}_2 = (a_1 - 2a_2)/3$, and $\delta^{(1)}_3 = (-2a_1 + a_2)/3$. The vectors to the six next-nearest-neighbor sites are given by $\delta^{(2)}_1 = a_1$, $\delta^{(2)}_2 = (a_1 - a_2)/3$, $\delta^{(2)}_3 = -a_2$, and $\delta^{(2)}_j = -\delta^{(2)}_{j-3}$ for $j = 4, 5, 6$. The hopping integrals are expressed as [19]

$$\gamma^{(i)}_{s,j} = \gamma \left[ 1 + \Delta k c \frac{a}{\sqrt{3}} \sin \phi_j - (\Delta k_z + is \Delta k_{so}) \frac{a}{\sqrt{3}} \cos \phi_j \right]$$

$$\gamma^{(2)}_{s,j} = i \frac{(-1)^{j+1}}{3\sqrt{3}} s \varepsilon_{so}.$$  \hspace{1cm} (A2)

$$\gamma^{(2)}_{s,j} = i \frac{(-1)^{j+1}}{3\sqrt{3}} s \varepsilon_{so}.$$  \hspace{1cm} (A3)
where $\gamma = -2.57\ eV$, $\phi_j = \theta - 5\pi/6 + 2\pi j/3$. Finally, $\theta = \arccos \frac{2n+m}{2\sqrt{n^2+m^2+nm}}$ is the chiral angle defined as the angle between $C_h$ and $a_1$, and $d_l = |C_h|/\pi = a\sqrt{n^2+m^2+nm}/\pi$ is the diameter of nanotube. The terms proportional to 

$$\Delta k_\ell = \zeta \frac{\sin 3\theta}{d_l^2}, \quad \Delta k_\ell = \beta \frac{\cos 3\theta}{d_l^2},$$  \tag{A4}$$

with $\zeta = -0.185$ nm, $\beta = 0.0436$ nm account for the curvature-induced shift of the Dirac point from the $K$ point in the axis and the circumferential directions, respectively. The pure imaginary hopping terms proportional to 

$$\Delta k_{so} = \alpha_1 V_{so} \frac{1}{d_l}, \quad \varepsilon_{so} = \alpha_2 V_{so} \frac{\cos 3\theta}{d_l},$$  \tag{A5}$$

represent the spin-dependent Dirac point shift in the circumferential direction and the Zeeman-like energy shift, respectively, induced by the spin-orbit interaction. We use $\alpha_1 = 8.8 \times 10^{-5}$ meV$^{-1}$, $\alpha_2 = -0.045$ nm and $V_{so} = 6$ meV. All numerical values above, except for $V_{so}$, have been obtained by fitting to the results of ab initio based tight-binding calculation in Ref. [7]. Note that the relation $(\gamma_{-x,j})^* = \gamma_{x,j} (t = 1, 2)$ holds reflecting the time-reversal symmetry.

2. Transformation of the $\Delta_1$ term to the BdG form

Here we show the transformation of the superconducting term proportional to $\Delta_1$ in Eq. (7) to the BdG form in Eq. (10). The operators can be doubled such as 

$$\sum_\mu e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) SC A_{\mu} C_{\ell j}^{(1)} - \mu}$$

$$= \frac{1}{2} \sum_\mu e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) S \left( C_{\ell j}^{(1)} - \mu \right) - C_{\ell j}^{(1)} - \mu}$$

$$= \frac{1}{2} \sum_\mu S \left( e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) C_{\ell j}^{(1)} - \mu} + e^{-i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) C_{\ell j}^{(1)} - \mu} \right),$$  \tag{A6}$$

From the second to the third equations, we have exchanged $\mu \leftrightarrow -\mu$ for the second term. Then, the contribution proportional to $\Delta_1$ in Eq. (7) is rewritten as 

$$\Delta_1 \sum_\mu e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) SC A_{\mu} C_{\ell j}^{(1)} - \mu} + H.c.$$ 

$$= \Delta_1 \frac{1}{2} \sum_\mu S \left( e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) C_{\ell j}^{(1)} - \mu} + e^{-i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) C_{\ell j}^{(1)} - \mu} \right) + H.c.$$ 

$$= \Delta_1 \frac{1}{2} \sum_\mu S e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) \left( C_{\ell j}^{(1)} - \mu + C_{\ell j}^{(1)} - \mu \right)} + H.c.$$ 

$$= \Delta_1 \frac{1}{2} \sum_\mu S e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) C_{\ell j}^{(1)} - \mu} C_{\ell j}^{(1)} - \mu} + H.c.,$$  \tag{A7}$$

where $c_{\sigma \ell \mu}^\dagger$, $c_{\sigma \ell \mu}$ are the Nambu spinors introduced in Eq. (8). From the second to third equations we have exchanged the term $\Delta_1 e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) C_{\ell j}^{(1)} - \mu}$ and its Hermite conjugate $\Delta_1 e^{i\frac{2\pi}{\beta} \delta_{lj}^{(1)}(\mu) C_{\ell j}^{(1)} - \mu}$.

Appendix B: BdG excitation spectrum of the bulk system

In this appendix, we show the detailed analytical calculation of the BdG excitation spectrum near the Dirac points. Such spectrum is obtained by diagonalizing the Hamiltonian matrix of Eq. (11), or, equivalently, Eq. (25). Hereafter, we omit the subscripts $\mu$, $\mu$ and $k$, for simplicity.

It follows from the chiral symmetry $\{ \Gamma, \tilde{H} \} = 0$ that for the eigenfunction $\Psi$ satisfying $\tilde{H}\Psi = \varepsilon \Psi$ there exists a paired state $\tilde{H}\Psi$ with the energy $-\varepsilon$, that is, $\tilde{H}\tilde{H}\Psi = -\varepsilon \tilde{H}\Psi$. And, multiplying the Schrödinger equation by the Hamiltonian, one gets $\tilde{H}^2\Psi = \varepsilon^2 \Psi$. Since $\tilde{H}$ has a block-off-diagonal form [see Eq. (25)], $\tilde{H}^2$ has the block-diagonal form with blocks $hh^\dagger$ and $hh^\dagger$. Then two separated equations, $hh^\dagger \Psi_x = \varepsilon^2 \Psi_x$ and $hh^\dagger \Psi_x = \varepsilon^2 \Psi_x$, are obtained, where $\Psi = (\Psi_x, \Psi_y)^T$. The eigenvalue problem can be reduced to solving the equation $\det \left[ hh^\dagger - \varepsilon^2 I_{2\times2} \right] = 0$, which gives,

$$\varepsilon^4 - 2 \left( \varepsilon^2 + \Delta_0^2 + |f_c|^2 + |f_c|^2 \right) \varepsilon^2 + \left[ (\varepsilon^2 - \Delta_0^2) - (|f_c|^2 - |f_c|^2) \right]^2 + 2\varepsilon c\Delta_0 + (f_c f_c^* + f_c f_c^*) = 0.$$  \tag{B1}$$

The equation $\det \left[ hh^\dagger - \varepsilon^2 I_{2\times2} \right] = 0$ is the same as Eq. (B1). Since the eigenvalue equation is quadratic in $\varepsilon^2$, we have

$$\varepsilon^2 = A \pm 2\sqrt{B},$$  \tag{B2}$$
with
\[ A = \varepsilon_c^2 + \Delta_0^2 + |f_e|^2 + |f_{eh}|^2, \quad (B3) \]
\[ B = (\Delta_0^2 + |f_e|^2) (\varepsilon_c^2 + |f_{eh}|^2) \]
\[ - \left( \frac{f_e f_{ch}^* + f_{eh}^* f_{eh}}{2} + \varepsilon_c \Delta_0 \right)^2. \quad (B4) \]

Then, the BdG spectrum is given by
\[ \varepsilon = \pm \sqrt{A \pm 2\sqrt{B}}. \quad (B5) \]

Let us focus on the BdG spectrum near the superconducting gap by expanding \( \varepsilon = \pm \sqrt{A - 2\sqrt{B}} \) near the Fermi points by using Eq. (15). Near the two Fermi points \( k_z = k_r \) \((r = \pm)\), which are given in Eq. (17), it holds \( \varepsilon_c = -\mu_{c,\tau} \), and
\[ f_e = f_{er} + c \gamma k', \quad f_{eh} \simeq f_{ehr} = \frac{\Delta_1}{\gamma} f_{er} + C, \quad (B6) \]
where \( k' \) is the 1D wave number measured from \( k_z = k_r \). Furthermore, \( f_{er} \) and \( f_{ehr} \) are \( f_e \) and \( f_{eh} \) at the Fermi point, respectively,
\[ f_{er} = c \gamma (k_r - \Delta k_z) + i (k_c - \Delta k_c,\tau), \quad (B7) \]
\[ C = c \Delta_1 \left( \tau \Delta k_z + i \Delta k_c,\tau \right), \quad (B8) \]
and we have discarded the weak \( k' \) dependence of \( f_{eh} \). Note that the relation \( |f_{er}| = |\mu_{c,\tau}| \) holds. \( A \) and \( B \) are expanded near each Fermi point as
\[ A = A_0 + A_1 k' + A_2 k'^2 + \cdots, \quad (B9) \]
\[ B = B_0 + B_1 k' + B_2 k'^2 + \cdots, \quad (B10) \]
where
\[ A_0 = 2\mu_{c,\tau}^2 + \Delta_0^2 + |f_{ehr}|^2, \quad (B11) \]
\[ A_1 = \gamma (c^* f_{er} + c f_{er}^*), \quad (B12) \]
and
\[ B_0 = \mu_{c,\tau}^4 + \mu_{c,\tau}^2 |f_{ehr}|^2 - \frac{1}{4} (f_{er} f_{ehr}^* + f_{er}^* f_{ehr})^2 \]
\[ - (f_{er} f_{ehr}^* + f_{ehr}^* f_{ehr}) \mu_{c,\tau} \Delta_0, \quad (B13) \]
\[ B_1 = \mu_{c,\tau}^2 \gamma (c^* f_{er} + c f_{er}^*) + c \gamma (c^* f_{er} + c f_{er}^*) |f_{ehr}|^2 \]
\[ - \frac{1}{2} (f_{er} f_{ehr}^* + f_{ehr}^* f_{ehr}) \gamma (c^* f_{ehr} + c f_{ehr}^*) \]
\[ - \gamma (c^* f_{ehr} + c f_{ehr}^*) \mu_{c,\tau} \Delta_0. \quad (B14) \]

Near the gap region, we have
\[ \varepsilon^2 = A - 2\sqrt{B} \]
\[ = (A_0 - 2\sqrt{B_0}) + \left( A_1 - \frac{B_1}{\sqrt{B_0}} \right) k' + \cdots. \quad (B15) \]

Using
\[ \sqrt{B_0} \simeq \mu_{c,\tau}^2 \left[ 1 + \frac{1}{2} \left( \frac{|f_{ehr}|^2}{\mu_{c,\tau}^2} - \frac{(f_{er} f_{ehr}^* + f_{ehr} f_{ehr}^*)^2}{4 \mu_{c,\tau}^4} \right) \right], \quad (B16) \]
each coefficient in Eq. (B15) is expressed as
\[ A_0 - 2\sqrt{B_0} = \left( \frac{\varepsilon_c^2}{2} \right)^2, \quad A_1 - \frac{B_1}{\sqrt{B_0}} \simeq 0, \quad (B17) \]
and we have discarded the higher order of \( \Delta_0/\mu_{c,\tau} \) and \( \Delta_0/\mu_{c,\tau}/\gamma \) in each contribution. The coefficient of \( k' \) in Eq. (B15) being zero means that the gap position is at \( k_z = k_{r,\tau} \) within this approximation. Therefore, \( \varepsilon_{c,\tau} \) represents the superconducting gap at \( k_z = k_{r,\tau} \). By comparing Eq. (29) and Eq. (B18), we get Eq. (35). By using Eqs. (B6)–(B8), we finally get the expression of the superconducting gap given in Eq. (18).

**Appendix C: Topological invariants**

In this appendix, we discuss properties of the winding number and other topological invariants.

1. Identity of two expressions for the winding number

Here we show the identity of two different expressions for the winding number; one is given by Eq. (24) and another is given using a flat-band Hamiltonian approach [46].

First, we shall get a flat-band Hamiltonian. Let us consider the filled and empty states \( \Psi_{\pm,l}(k) \) of the Hamiltonian (25) with the eigenvalue \( \pm \varepsilon_l(k) \), where \( - \) (+) refers to the filled (empty) state and \( \varepsilon_l(k) > 0 \). The eigenfunctions are written as [47]
\[ \Psi_{\pm,l}(k) = \frac{1}{\sqrt{2}} \left( \pm \frac{1}{\varepsilon_l(h)} h^l(k) u_l \right), \quad (C1) \]
where \( l \) is the index of the spectrum and we have omitted the subscript \( \mu \) for simplicity. One can check that the function satisfies the Schrödinger equation \( \hat{H}(k) \Psi_l(k) = \pm \varepsilon_l(k) \Psi_l(k) \) with the relation \( h(k) h^l(k) u_l = \varepsilon^2_l(k) u_l \), which is derived by multiplying the Schrödinger equation by the Hamiltonian. \( A \ priori \) the eigenvectors \( u_l \) may depend on \( k \). Nevertheless, since \( u_l \) are eigenvectors
of \(h(k)h^\dagger(k)\) which is Hermitian, they form an orthogonal set. We can perform a unitary transformation into a basis in which \(hh^\dagger\) is diagonal, and the eigenvectors \(u_l\) are independent of \(k\). This transformation is continuous in \(k\), which is assured by the continuity of the original eigenvectors \(u_l(k)\). In the following, we shall work implicitly in that transformed basis. The projector onto the filled states is given by

\[
P = \sum_l \Psi_{-,l}(k)\Psi_{-,l}(k)^\dagger = \frac{1}{2} I - \frac{1}{2} Q. \tag{C2}
\]

The operator \(Q\) acts as a flat-band Hamiltonian having the energy +1 for the empty states and -1 for the filled states independent of \(k\) since \(Q\Psi_{\pm,l}(k) = (I - 2P)\Psi_{\pm,l}(k) = \pm\Psi_{\pm,l}(k)\). In the matrix form, we have

\[
Q = \begin{pmatrix} 0 & q(k) \\ q^\dagger(k) & 0 \end{pmatrix}, \tag{C3}
\]

where

\[
q(k) = \sum_l \frac{1}{\varepsilon_l(k)} u_l u_l^\dagger h(k) = U(k)h(k), \tag{C4}
\]

and the matrix

\[
U(k) = \sum_l \frac{1}{\varepsilon_l(k)} u_l u_l^\dagger \tag{C5}
\]

has been introduced. Using the flat-band Hamiltonian, a winding number is defined as [46]

\[
w' = \frac{1}{4\pi i} \int dk \text{Tr} \left[q^{-1}(k)\partial_k q(k)\right], \tag{C6}
\]

where the integral is taken over the whole of the 1D BZ.

Before showing the identity of the two different definitions of the winding number, let us show a relation which will be used later. Hereafter, we will also omit \(k\) in the expressions for simplicity. Since \(Q^2 = (I - 2P)^2 = I - 4P + 4P^2 = I\), we have \(qq^\dagger = 1\). Then, \(q^{-1} = q^\dagger\). We also have \(U^\dagger = U\), which is immediately seen from Eq. (C5). From these two relations we have \(h^{-1}U^{-1} = h^\dagger U^\dagger = h^\dagger U\). Then, it holds

\[
U^{-1} = hh^\dagger U = \sum_l \varepsilon_l u_l u_l^\dagger. \tag{C7}
\]

Let us show the identity of \(w'\) in Eq. (C6) with \(w\) in Eq. (24). Since \(0 = \partial_k (q^{-1}q) = (\partial_k q^{-1})q + q^{-1}\partial_k q\), the integrand in the expression of the winding number \(w'\) is written as

\[
\text{Tr} \left[q^{-1}\partial_k q\right] = \frac{1}{2} \text{Tr} \left[q^{-1}\partial_k q - q\partial_k q^{-1}\right]. \tag{C8}
\]

By using the relations \(\partial_k q = (\partial_k U)h + U\partial_k h\), \(\partial_k q^{-1} = (\partial_k h^{-1})U^{-1} + h^{-1}\partial_k U^{-1}\), and the cyclic property of the trace, we have

\[
\text{Tr} \left[q^{-1}\partial_k q - q\partial_k q^{-1}\right] = \text{Tr} \left[(h^{-1}\partial_k h - h\partial_k h^{-1}) + (U^{-1}\partial_k U - U\partial_k U^{-1})\right]. \tag{C9}
\]

The second term is rewritten as

\[
\text{Tr} \left[U^{-1}\partial_k U - U\partial_k U^{-1}\right] = \text{Tr} \left[U^{-1}\partial_k U - \partial_k (UU^{-1}) + (\partial_k U) U^{-1}\right] = 2\text{Tr} \left[U^{-1}\partial_k U\right]. \tag{C10}
\]

By using Eq. (C7), the term is further calculated as

\[
\text{Tr} \left[U^{-1}\partial_k U\right] = \text{Tr} \left[\sum_{ll'} \left(-\varepsilon_l \frac{\partial_k \varepsilon_{l'}}{\varepsilon_{l'}}\right) u_l^\dagger u_{l'} u_{l'}^\dagger u_l\right] = -\sum_l \partial_k \log \varepsilon_l, \tag{C11}
\]

where we have used the orthogonality \(u_l^\dagger u_{l'} = \delta_{ll'}\) and \(\text{Tr}[u_l^\dagger u_l] = \sum_m u_m^\dagger u_m^\dagger = 1\). Using the periodicity of \(\varepsilon_l(k)\) in the BZ, we finally get the identity

\[
w' = \frac{1}{4\pi i} \int dk \text{Tr} \left[h^{-1}\partial_k h - h\partial_k h^{-1}\right] = -\frac{1}{4\pi} \int dk \text{Tr} \left[\tilde{\Gamma}\tilde{H}^{-1}\partial_k \tilde{H}\right] = w. \tag{C12}
\]

2. Winding number near the Dirac points

Let us show the analytical calculation of the winding number near the Dirac points. First we show how to derive the expression (28) from Eq. (24). Using the unitary matrix (23) and the transformed Hamiltonian (25), the winding number is expressed as

\[
w_\mu = -\frac{1}{4\pi i} \int dk \text{Tr} \left[\tilde{\Gamma}\tilde{H}_\mu^{-1}\partial_k \tilde{H}_\mu\right] = \frac{1}{4\pi i} \int dk \text{Tr} \left[\mu^{-1}\partial_k h \mu - h^{-1}\partial_k h\right] = \frac{1}{4\pi i} \int dk \left(\partial_k \log \det h - \partial_k \log \det h^\dagger\right) = \frac{1}{2\pi} \text{Im} \int dk \partial_k \log \det h = w. \tag{C13}
\]

where we have used the formulas

\[
\text{Tr} \left[h^{-1}\partial_k h\right] = \partial_k \log \det h, \tag{C14}
\]

\[
\log \det h^\dagger = \text{Re} (\log \det h) - i\text{Im} (\log \det h). \tag{C15}
\]

Next, we will show the calculation leading from Eq. (32) to Eq. (34). Near the \(\tau\) point the imaginary part of \(\text{det} h_\mu\) is given by

\[
\frac{\text{Im} \left(\text{det} h_\mu\right)}{2s} = \mu_{c,\tau} \Delta_0 + |c|^2 \gamma_\Delta \left|k_z\right| (k_z - \tau \Delta k_z) + k_c (k_c - \Delta k_{c,\tau}). \tag{C16}
\]
At the Fermi points \( k_z = k^\uparrow \) the imaginary part is calculated as
\[
\frac{\text{Im} \left( \det h_{\sigma}^{(\tau)} \right)}{2s} = \frac{\gamma}{\mu_{\sigma,\tau}^2} \Delta_0 = \frac{\gamma}{\mu_{\sigma,\tau}^2} + \frac{\Delta_1}{\Delta_0} (1 + \varepsilon_{c,\tau} E_{c,\tau})
\]
\[-r \frac{\Delta_1}{\Delta_0} \varepsilon_{c,\tau} \text{sgn}(\mu_{c,\tau}) \sqrt{1 - E_{c,\tau}^2}.
\]
Then, the condition (32) is summarized in the form of Eq. (34).

### 3. Relation between \( Z \) and \( Z_2 \) invariants

We have shown that an integer (\( Z \)) topological invariant, the winding number, can be defined for our system. The periodic table of topological invariants [48] nevertheless states that a DIII class Hamiltonian has a paritylike \( Z_2 \) invariant. These two facts appear contradictory, but are not, as we will now clarify. The discussion is based on the approach to topological invariants presented in the review by Chiu et al [48].

The fundamental topological invariant in 1D is Zak’s phase [49] in one band carrying a generic index \( l \),
\[
\gamma_l = \frac{i}{2\pi} \int_{BZ} dk \mathcal{A}_l(k),
\]
(C18)
where \( \mathcal{A}_l(k) \) is the Berry connection in band \( l \), \( \mathcal{A}_l(k) = \langle \Psi_l(k) | \partial_k | \Psi_l(k) \rangle \), and \( | \Psi_l(k) \rangle \) is the eigenfunction of a 1D bulk Hamiltonian for eigenvalue \( \varepsilon_l \). Since the Berry connection is gauge dependent, so is Zak’s phase, but it can be shown that a gauge transformation changes \( \gamma_l \) only by an integer. The more frequently used invariant is therefore \( W = \exp(2\pi i \sum_l \gamma_l) \), where \( l \) are the indices of filled bands, which is gauge independent, although in general not quantized. The presence of discrete symmetries restricts the values which \( \gamma_l \) can take. In systems with chiral symmetry, in the gauge given by the chiral basis the winding number can be shown to be \( Z \ni w_l = 2\gamma_l \), therefore \( W = \exp(i\pi \sum_l w_l) = \pm 1 \). In systems with particle-hole symmetry the topological invariant \( W \) can be evaluated using the representation of the Hamiltonian in the Majorana basis,
\[
\mathcal{H}(k) = U_M^l[iX(k)]U_M.
\]
(C19)

At time reversal invariant momenta \( k = 0, \pi, X(k) \) is real and skew-symmetric, \( X(k) = -[X(k)]^T \). The topological invariant \( W \) can then be expressed through the Pfaffian of \( X \),
\[
W = \text{sgn} \left\{ \text{Pf}[X(\pi)] \text{Pf}[X(0)] \right\} = \pm 1,
\]
(C20)
which is of a \( Z_2 \) type. In our system the complete 16 x 16 Hamiltonian \( \mathcal{H}(k) \) has the four-block-diagonal form,
\[
\mathcal{H}(k) = \text{diag} \left[ H_{(\mu,K,\uparrow)}(k), H_{(\mu,K,\downarrow)}(k), H_{(\mu,K,\downarrow)}(k), H_{(\mu,K,\uparrow)}(k) \right],
\]
(C21)
where \( H_\mu \) are defined in Eq. (11). The transformation \( U_M \), which brings the system into the Majorana basis, acts in the upper two and the lower two blocks separately, given as \( U_M = \text{diag}[U_M', U_M'], \) where
\[
U_M' = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 1 \ 0 & i & 0 & 0 & 0 & 0 \ 0 & 0 & 1 & 0 & 0 & 0 \ 0 & 0 & 0 & i & 0 & 0 \ 0 & 0 & 0 & 0 & i & 0 \ 0 & 0 & 0 & 0 & 0 & i \ \end{pmatrix},
\]
(C22)
resulting in
\[
X(k) = \text{diag} \left[ X_{(\mu,K,\uparrow),(\mu,K,\downarrow)}, X_{(\mu,K,\downarrow),(\mu,K,\uparrow)} \right].
\]
(C23)
The Pfaffian at \( k = 0, \pi \) is given by
\[
\text{Pf}[X(k)] = \text{Pf}[X_{(\mu,K,\uparrow),(\mu,K,\downarrow)}] \text{Pf}[X_{(\mu,K,\downarrow),(\mu,K,\uparrow)}],
\]
(C24)
where
\[
\text{Pf}[X_{\mu,\mu'}] = \left[ (\varepsilon_{c,\mu} - \Delta_0) - (|f_{c,\mu}|^2 - |f_{c,h,\mu}|^2) \right]^2 + \left[ 2\varepsilon_{c,\mu} \Delta_0 + (f_{c,\mu} f_{c,h,\mu}^* + f_{c,h,\mu} f_{c,\mu}^*) \right]^2.
\]
(C25)
Since the Pfaffian is always non-negative, the topological invariant \( W \) is also trivial. Indeed, our total winding number is always even, \( w = \sum_{\mu} w_\mu = 0, \pm 2 \), therefore, the corresponding \( W = 1 \). Our nanotube from the \( Z_2 \) point of view is always in the trivial phase. Nevertheless, a total invariant does not give the full information about the system. It is especially clear in quantum spin Hall insulators, where the total Chern number, summed over two spin directions, vanishes but the edge states exist for both spins and even are topologically protected [50]. The information carried by the partial invariants is therefore more useful.

As a last remark, in contrast to the topological insulators, the edge states generated by the four \( \mu \) subspaces of our system are not topologically protected, as can be seen from Figs. 8(d) and 8(e), where the valley mixing clearly gaps them. Our system is then more similar to a weak topological insulator, where the states generated by the nontrivial weak partial invariant can be gapped by disorder, i.e., a breaking of translational invariance [51].
Appendix D: Analysis of the 1D continuum model

In this appendix, we will show the detailed calculation of the modes of the 1D continuum model introduced in Sec. V. The condition that the determinant of the matrix in Eq. (42) is zero is written as

\[(\mu_{c,\tau} - ips\Delta_0)^2 - |c|^2 [\gamma (q - \tau \Delta k_z) + ips\Delta_1 q]^2 + |c|^2 [i\gamma (k_c - \Delta k_c) - ps\Delta_1 k_c]^2 = 0. \tag{D1}\]

This is a second-order equation in \(q\), and the two solutions are given by,

\[q^{(\tau)}_\pm = \frac{1}{|c| (\gamma + ips\Delta_1)} \left[ \pm \sqrt{(\mu_{c,\tau} - ips\Delta_0)^2 - |c|^2 [\gamma (k_c - \Delta k_c) + ips\Delta_1 k_c]^2 + |c|^2 [\gamma \tau \Delta k_z]} \right] \tag{D2}\]

where the signs \(-\) and \(+\) in the index of \(q^{(\tau)}_\pm\) correspond to the signs of \(+\) and \(-\) in the right-hand side, respectively, and

\[F = \frac{1}{\mu_{c,\tau}} \frac{\Delta_0 + \Delta_1 E_{c,\tau} (E_{c,\tau} + \varepsilon_{c,\tau})}{1 - E_{c,\tau}^2}. \tag{D3}\]

Note that \(F\) is of the order of \(\Delta_0/\mu_{c,\tau}\). By using the formula

\[\sqrt{a + ib} = \sqrt{\frac{a + \sqrt{a^2 + b^2}}{2}} + i \text{sgn}(b) \sqrt{-\frac{a + \sqrt{a^2 + b^2}}{2}}, \tag{D4}\]

for \(a, b \in \mathbb{R}\), the term \(\sqrt{1 - 2ipsF}\) becomes,

\[\sqrt{1 - 2ipsF} = R + iI, \tag{D5}\]

where \(R\) and \(I\) are given by

\[R = \sqrt{1 + \frac{1 + (2psF)^2}{2}} \approx \sqrt{1 + 1 + \frac{1}{2} (2psF)^2} \approx 1, \tag{D6}\]
\[I = \text{sgn}(-2psF) \sqrt{-\frac{1 + \sqrt{1 + (2psF)^2}}{2}} \approx -ps \text{sgn}(F) \sqrt{-\frac{1 + 1 + \frac{1}{2} (2psF)^2}{2}} = -ps.\]

Then, for the real part of \(q_{\tau,\pm}\), we get

\[\text{Re} (q_{\tau,\pm}) = \mp \frac{\gamma R + ps\Delta_1 I}{|c|^2} \sqrt{\frac{\mu_{c,\tau}^2 - |c|^2 (k_c - \Delta k_c)^2 + \tau \Delta k_z}{2}} \approx \pm \sqrt{\left(\frac{\mu_{c,\tau}}{|c| \gamma}\right)^2 - (k_c - \Delta k_c)^2 + \tau \Delta k_z} = k_\pm. \tag{D7}\]

On the other hand, for the imaginary part of \(q_{\tau,\pm}\),

\[\text{Im} (q_{\tau,\pm}) = \frac{1}{|c| \gamma} \left( \mp \frac{I - ps\Delta_1 R}{\gamma} |\mu_{c,\tau}| \sqrt{1 - E_{c,\tau}^2 - ps \frac{\Delta_1}{\gamma} |c| \gamma \Delta k_z} \right), \tag{D8}\]

and the numerator of the first term in the right-hand side is calculated as,

\[\gamma I - ps\Delta_1 R = \frac{-ps}{1 - E_{c,\tau}^2} \left[ \frac{\gamma}{\mu_{c,\tau}} \Delta_0 + (1 + E_{c,\tau} \varepsilon_{c,\tau}) \Delta_1 \right]. \tag{D9}\]
Then, we get

$$\text{Im}(q_{\tau, \pm}) = \pm \frac{ps}{|c|\gamma} \left\{ \frac{1}{\sqrt{1 - E_{c, \tau}^2}} \left[ \frac{\gamma}{\mu_{c, \tau}} \Delta_0 + (1 + E_{c, \tau} \varepsilon_{c, \tau}) \Delta_1 \right] \frac{|\mu_{c, \tau}|}{\gamma} \pm \tau \Delta_1 \varepsilon_{z, \tau} \frac{\mu_{c, \tau}}{\gamma} \right\}$$

$$= \pm \frac{ps}{|c|\gamma} \frac{\text{sgn}(\mu_{c, \tau})}{\sqrt{1 - E_{c, \tau}^2}} \left[ \Delta_0 + \Delta_1 \frac{\mu_{c, \tau}}{\gamma} \left( 1 + E_{c, \tau} \varepsilon_{c, \tau} \pm \text{sgn}(\mu_{c, \tau}) \varepsilon_{z, \tau} \sqrt{1 - E_{c, \tau}^2} \right) \right]$$

$$= \pm \frac{ps}{|c|\gamma} \frac{\text{sgn}(\mu_{c, \tau})}{\sqrt{1 - E_{c, \tau}^2}} \frac{\varepsilon_{z, \tau}}{2},$$

which is the expression given in Eq. (44).
