ABSTRACT

Aspiration pneumonia (AP) has been recognized as one of the most common postoperative complications after hip surgery in elderly. The objective of the present study was to evaluate risk for postoperative complications of AP in elderly patients with femoral neck fractures. We recruited 221 female patients (age 84.9 ± 7.1 years) with a history of hip surgery carried out at Toyama Municipal Hospital. AP occurred in 11 out of 276 cases (3.99%). Fisher’s exact test have found significant differences in gender, serum albumin level, cognitive impairment, and history of osteoporosis, between AP and non-AP groups. Subsequently multiple logistic regression analysis was conducted to investigate the risk factors for AP, including age, body mass index (BMI), serum albumin, cognitive impairment, and activities of daily living (ADL). Univariate odds ratio showed significant differences in age and cognitive disorder, although adjusted odds ratio of these variables showed no significant association with AP incidence. This study suggested that serum albumin and cognitive function seemed to be the weak risk factors for AP but were necessary to assess under adjustment of confounding factors, including age, gender and BMI. Taking account of cognitive functional assistance seemed to be important for the postoperative management of AP, especially in elderly patients receiving surgery of femoral neck and trochanteric fractures.

KEYWORDS: Elderly; Hip fractures; Aspiration pneumonia; Age; Cognitive impairment

ABBREVIATIONS: AP: Aspiration Pneumonia; BMI: Body Mass Index; ADL: Activities of Daily Living
INTRODUCTION

The incidence of hip fracture in the elderly has been increased rapidly from 1.7 million in 1990 to an estimated 6.3 million in 2050 worldwide [1]. Approximately one third of these patients die within the first year [2]. A nationwide survey of hip fractures by the Japanese Orthopaedic Association (JOA) from 1998 to 2008 found a drastic increase in incidence [3]. As a consequence, geriatric and orthopedic collaboration (orthogeriatrics) has been organized in different ways in Japan. Such collaboration has been conducted in Toyama city, which locate in the middle district in Toyama Prefecture which has an area of approximately 1,200 square kilometers and has about four hundred thousand residents [4]. The proportion of elderly people aged 65 and over to all the residents in Toyama city is over 30%. Toyama Municipal Hospital is a core hospital in Toyama Prefecture which has approximately 600 beds. In the hospital, an Elderly Bone Femoral Neck and Trochanteric Fracture Center has been installed with advanced technology and dedicated staffs to conduct surgery in patients with acute phase femoral neck and trochanteric fracture. Co-management of hip fracture patients by orthopedic surgeons and geriatricians is suggested to be effective to reduce length of hospital stay without negatively affecting major patient outcomes [2]. On this account, multidisciplinary cooperation could be effective as conducted in Toyama Municipal Hospital.

The cause of mortality in elderly people with hip fractures mostly attributed to postoperative complications, such as wound infections, pneumonia, deep venous thrombosis, respiratory and urinary infections and cardiovascular events [5-12]. The consequences of hip fractures in elderly persons also include a deterioration in functional capacity to perform activities that enable independent living [13,14].

Among these patients, cases of complicated pneumonia are frequently encountered, but there are few reports investigated complications of pneumonia [14,15]. Therefore, the present study was retrospectively investigated on the cases suffering aspiration pneumonia which was hospitalized for femoral fracture and received operation and rehabilitation. In addition, we examined risk factors for pneumonia, particularly focusing on risk factors for aspiration pneumonia to identify some measures to raise the patient’s QOL.

MATERIALS AND METHODS

This retrospective study was carried out under approval (2018-06) of the Clinical Research Ethics Committee of Kanazawa Medical University. Demographic data were collected by physicians, specialist nurses, pharmacists, and medical affairs. The existence of the aspiration pneumonia was also examined in the same division. Body mass index (BMI) was calculated as weight (kg) divided by the square of height (m²). Waiting time (day) from hospitalization to entering the operating room was also calculated on each case.

The aspiration pneumonia was diagnosed by postoperative chest X-ray by radiologists. The cases were defined as positive of aspiration pneumonia (AP positive) and others were defined as negative of aspiration pneumonia (AP negative). Serum albumin concentration was measured and the value itself was used for the following statistical analysis as continuous variables. In addition, the data were divided into high albumin (≥3.5g/dL) and low albumin (<3.5g/dL) groups that were used for the following analysis as dichotomous variables.

Cognitive disorders were diagnosed by neuropsychiatrists. Degree of independence in everyday life on each case was assessed by a conventional ADL scale, which is classified by the four groups (J, A, B, C). The group J is mostly assistance-free, the group A is semi-bedridden mostly active during daytime, the group B is bedridden requiring assistance for daily activities, and the group C is bedridden requires assistance in bed [16,17]. We divided them into two groups, J A (assistance non-required), and B C (assistance-required) group.

Data of history of hypertension, diabetes mellitus, circulatory disease, respiratory disease, renal disease, bone fracture and osteoporosis were collected from medical records of the cases. The present study consists of continuous data, such as age, BMI, waiting time, serum albumin concentration, which were statistically evaluated by mean, standard deviation and Student’s t-test. The present study also consists of dichotomous data, such as categorized serum albumin concentration, cognitive disorder, ADL, and history of diseases, which were statistically evaluated by Fisher’s exact test.

Logistic regression analyses were performed using dichotomous AP positive and AP negative as dependent variables, and age, BMI, serum albumin, cognitive disorder and ADL as independent variables. All statistical analyses were two-tailed, p < 0.05 regarded as significant, including Student’s t-test, chi-square test and logistic regression analyses performed using EZR.

RESULTS

Initially 321 patients were admitted to the Toyama Municipal Hospital from January 1st, 2016, to December 31st, 2017, excluding 16 patients younger than 65 years, 7 patients with conservative treatment, 8 patients with multiple trauma, 2 patients with pathologic fracture, 1 patient with hospital transfer, 3 patients with in-hospital falls, and 7 patients with no measurement of serum albumin. Finally, 276 patients were included and used as an analysis set of the present study.

Table 1 shows patient characteristics at the enrollment in this study. The patient population (N=276) were divided into AP negative (N=265) and AP positive (N=11) groups. BMI, waiting time, history of hypertension, history of diabetes mellitus, history of circulatory disease, history of respiratory disease, history of renal disease and history of bone fracture showed no significant differences between the groups. On the other hand, age, gender, serum albumin, categorized serum albumin, cognitive impairment and history of osteoporosis showed significant differences between the groups (p<0.001, 0.046, 0.033, 0.007, 0.011 and <0.001, respectively).

Table 2 shows the univariate and multiple logistic regression analysis. Univariate analysis showed that cognitive impairment (OR 12.50, 95% CI 1.09–143, p = 0.0425) as well as age (OR 1.50, 95% CI 1.05–2.16, p = 0.0277) were associated with the occurrence of AP. On the other hand, multivariate analysis showed no significant association with the occurrence of AP.

Figure 1 shows the ROC curve of the logistic models, AP positive and AP negative as dichotomous dependent variables, and age, BMI, albumin, cognitive disorder and ADL as independent variables. The area under the curve and its 95% confidence intervals are as follows: 0.967 (0.893-1.040)

DISCUSSION

Hip fracture is a common cause of long hospital stay in the
elderly. In the Japanese practice guideline for treatment of hip fractures suggested that pneumonia is the most common postoperative complication of hip fractures, with an incidence of 3.2%, and the pneumonia is a most common complication of death during hospitalization, accounting for 30 to 44% [9] through our study showed 11 cases in 276 total cases, i.e., approximately 4%, previous studies of hip fractures caused by falls have shown rates of complications of pneumonia before and after surgery ranging from 7 to 9% [10-12] Most evidence guiding perioperative medical risk management of patients undergoing hip fracture repair focuses on cardio and thromboembolic risk [9], but the present study suggests aspiration pneumonia as one of the important complications for elderly patients after hip fracture repair.

**Table 1**: Patient characteristics at baseline.

| Variable                        | AP Negative N=265   | AP Positive N=11 | *p-value   |
|---------------------------------|---------------------|------------------|------------|
| Age (Mean ± S.D.)               | 84.6±7.0            | 91.8±6.4         | <0.001     |
| Gender, Female: N (%)           | 215(81.1)           | 6 (17.6)         | 0.046      |
| BM (Mean ± S.D.)                | 21.7±8.5            | 19.5±4.3         | 0.425      |
| Waiting Time (Day, Mean ± S.D.) | 1.7±2.5             | 1.3±1.2          | 0.629      |
| Albumin (Mean ± S.D.)           | 3.6±0.6             | 3.2±0.5          | 0.033      |
| Albumin, >3.5g/dL: N (%)        | 182 (68.7)          | 3 (8.8)          | 0.007      |
| Cognitive Impairment: N (%)     | 134 (50.6)          | 10 (29.4)        | 0.011      |
| ADL, Assistance Required: N (%)| 44 (16.6)           | 4 (11.8)         | 0.104      |
| History of Hypertension N (%)   | 158 (59.6)          | 4 (11.8)         | 0.209      |
| History of Diabetes Mellitus: N | 53 (20.0)           | 0 (0.0)          | 0.131      |
| History of Circulatory Disease: N (%) | 75 (28.3) | 2 (5.9)         | 0.733      |
| History of Respiratory Disease: N (%) | 32 (12.1) | 3 (8.8)       | 0.151      |
| History of Renal Disease: N (%)  | 24 (9.1)            | 1 (2.9)          | 1.000      |
| History of Bone Fracture: N (%) | 85 (32.1)           | 5 (14.7)         | 0.346      |
| History of Osteoporosis: N (%)  | 249 (94.0)          | 5 (14.7)         | <0.001     |

**Table 2**: Results of logistic regression analysis.

| Coefficients | S.E. | p-value | Univariate Odds Ratio | 95% CI | Adjusted Odds Ratio | 95% CI |
|--------------|------|---------|-----------------------|--------|---------------------|--------|
| Age          | 0.807| 0.445   | 0.070                 | 1.502  | 1.046-2.159         | 2.242  | 0.937-5.367 |
| BMI          | 0.056| 0.200   | 0.779                 | 0.839  | 0.632-1.114         | 1.058  | 0.714-1.567 |
| Albumin      | 0.425| 1.060   | 0.688                 | 0.821  | 0.291-2.316         | 1.530  | 0.192-12.213 |
| Cognitive    | 6.125| 4.115   | 0.137                 | 12,500 | 1.089-14.34         | 457.337| 0.144-1000 |
| ADL          | -3.054| 2.547  | 0.230                 | 2.000  | 0.272-14.699        | 0.047  | 0.0003-6.938 |

Figure 1: ROC curves of the logistic regression model.
occurrence is less associated with history of such diseases. The results of the multiple logistic regression analyses were shown in Table 2, which suggested that serum albumin, cognitive impairment and ADL were not associated with the occurrence of AP under adjustment of age and BMI as covariates using appropriate logistic model (ROC_AUC=0.967).

The present study showed association of serum albumin level with occurrence with AP in the patient background. Consistent with our results, Metani et al. [15], also reported significant reduction in serum albumin in AP cases. They also indicated lower BMI in AP cases, indicating that patients with low BMI, including low nutritional cases, can have lower resistance to infection. The calculation of the cut-off value by future research is meaningful from the viewpoint of the prevention of the pneumonia.

Complications of pneumonia do not necessarily directly lead to death, but they are anticipated to result in decreased motor function and other physical activity. Aspiration pneumonitis associated with cerebrovascular accident has been reported to result in a marked decrease in Barthel Index and Modified Rankin scale [18]. Although the present study is a retrospective research, it could provide insight with respect to aspiration pneumonia as a risk factor in patients with hip fracture. And based on the results of this study, we treat perioperative complications under the multidisciplinary cooperation and improve the quality of life of elderly patients after discharge [19,20]. Future investigations into the association between aspiration pneumonia and physical activity will be expected.

CONCLUSION

In conclusion, we retrospectively evaluated the risk factors for AP in patients with femoral neck and trochanteric fractures, showed that serum albumin and cognitive function seemed to be the weak risk factors for AP but were necessary to assess under adjustment of confounding factors, including age, gender and BMI. Assistance of cognitive function seemed to be important for the postoperative management of AP, specifically in elderly patients receiving surgery of femoral neck and trochanteric fractures.
