Abstract: Wave energy has the advantages of high energy density, renewability, and wide distribution, and has been highly valued by many coastal countries. The wave energy conversion device can convert wave energy into electric energy, which is of great significance for alleviating problems such as energy crisis and greenhouse effect. The traditional wave energy conversion device can only gain the energy along the heave direction, and the kinetic energy of the buoy is not fully utilized. To improve the energy utilization efficiency of the wave energy conversion device, this paper proposed a new type of 3-SPS wave energy conversion device. Based on linear waves and Lagrangian equation, a hydrodynamic model of the device was established. The displacement and velocity of the device float under the action of linear waves were analyzed. The results show that the 3-SPS wave energy conversion device can collect the kinetic energy of the buoy in its heaving, surging and pitching movement at the same time; the kinetic energy of the buoy in the heaving direction is much greater than the kinetic energy in the surging and pitching directions; the buoy can capture kinetic energy in multiple directions of motion, indicating that the 3-SPS wave energy conversion device has a high energy utilization efficiency. This paper provides some useful references for the optimal design of the new wave energy device.

1 Introduction

As a kind of clean energy, wave energy has the characteristics of large reserves, high energy flow density, wide distribution, and easy conversion of energy forms [1], and has been highly valued by many coastal countries. In December 2016, the “13th Five-Year Plan for Energy Technology Innovation” issued by the National Energy Administration of China pointed out that research on high conversion rate wave energy power generation technology and research and development of wave energy power generation devices is one of the important tasks of energy technology innovation planning. China is a large maritime country with a total coastline of more than 32,000 kilometers, and the usable wave energy is very abundant [2-3]. Therefore, research on wave energy power generation technology is of great significance for ensuring energy security, maintaining sustainable economic and social development, and enhancing the international competitiveness of marine technology in China.

The wave energy conversion device can realize the conversion of wave energy to electric energy [4-6]. The buoy-type wave energy conversion device is one of the research hotspots in the field of wave energy power generation technology [7-9]. Under the action of waves, the buoy produces motion in 6 directions, namely: yawing, heaving, pitching, swaying, rolling and surging. The traditional single-degree-of-freedom wave energy conversion device only collects the energy of the buoy along the heaving direction, and the kinetic energy of the buoy in other directions is not fully utilized, which limits the energy capture efficiency of the single-degree-of-freedom wave energy conversion device to a certain extent. Traditional methods to improve the energy capture efficiency of the device often focus on how to optimize the shape and size of the buoy, and ignore the influence of the freedom of the device on the energy capture efficiency. For this reason, this paper proposed a new type of 3-SPS wave energy conversion device, which can collect the energy in the heaving, surging and pitching directions at the same time. The hydrodynamic model of the device was established thought the Lagrangian method. Based on the Runge-Kutta method, the hydrodynamics of the device was simulated, and the kinematic characteristics of the device were obtained. Finally, the energy utilization efficiency of the device was analyzed.

2 Wave model

Wave models mainly include linear waves, nonlinear waves and random waves. This paper mainly studied the hydrodynamic characteristics of 3-SPS wave energy conversion under the action of linear waves. Linear wave refers to a wave with a sinusoidal profile [164], and its schematic diagram is shown in Figure 1.
The parameters of the linear wave shown in Figure 1 are as follows:

- \( h \): Water depth, refers to the distance from the bottom of the water to the surface of still water.
- \( H \): Wave height, refers to the depth from the crest to the trough.
- \( \lambda \): Wavelength, refers to the distance between two adjacent wave crests.
- \( \eta \): Vertical free surface displacement, which is a function of displacement \( x \) in the direction \( X \) and \( t \).
- \( c \): Wave speed.

2.1 Wave dynamics model

The motion of the water mass points that make up the linear wave can be described by its velocity potential. Assuming that the flow below the free surface of water is a non-rotational fluid, its velocity potential is:

\[
\mathbf{V} = \nabla \phi
\]

For the stable incompressible fluid, there is:

\[
\nabla^2 \phi = 0
\]

Equation (2) is an elliptic partial differential equation, which can be solved by applying boundary conditions (free surface condition of motion, seabed condition and dynamic free surface condition), and the velocity potential \( \phi \) can be obtained as follows:

\[
\phi^+ = \pm \frac{H}{2} \frac{g}{k c} \frac{\cosh[k(z+h)]}{\cosh(kh)} \sin[k(x \mp ct)]
\]

\( \phi^+ \) takes “+” to indicate right-traveling waves and “-” to indicate left-traveling waves. In this paper, we assume that the linear wave studied is a right-traveling wave, and the free surface displacement is:

\[
\eta = \frac{H}{2} \cos[k(x - ct)]
\]

The wave number \( k \) is as follows:

\[
k = \frac{2\pi}{\lambda}
\]

The time difference between two consecutive peaks is the period \( T \) of the linear wave. From equation (5), we can know that:

\[
kc = \frac{2\pi}{T} = 2\pi f = \omega
\]

2.2 Wave energy model

From the previous research [165], the energy and power of the linear wave can be obtained as:

\[
E = \frac{\rho g H^3}{8} \frac{h^3}{T^3} \frac{1}{Th^3}
\]

\[
P = \frac{\rho g H^3 c^3}{16} \left[ \frac{2kh}{\sinh(2kh)} + 1 \right]
\]

3 Dynamic model of 3-SPS wave energy conversion device

The 3-SPS wave energy conversion device proposed in this paper is shown in Figure 2. The device consists of a buoy, four linear generators connected with the buoy, and a spring. The length and width of the buoy are both \( L \) and the height is \( D \). The lower platform \( A_1A_2A_3 \) is fixed to the seabed by a spherical pair, and its shape is a regular triangle with a side length of \( L \). The spring coefficients of springs \( A_1B_2, A_2B_3, \) and \( A_3B_1 \) are \( K \), and their original lengths are \( L_{01}, L_{02}, \) and \( L_{03} \), respectively. The origin of the static coordinate system is fixed at the center of the lower
platform, and the direction of the coordinate axis is shown in Figure 2. The dynamic model of the energy conversion device is established based on the Lagrangian method. The general form of the equation is:

$$\frac{d}{dt} \frac{\partial T}{\partial \dot{q}_i} - \frac{\partial T}{\partial q_i} + \frac{\partial U}{\partial \dot{q}_i} = Q_i$$  \hspace{1cm} (12)$$

In the equation, $T_k$ is the total kinetic energy of the system; $U$ is the total potential energy of the system; $Q$ is the non-conservative generalized force; $q$ is the generalized coordinate.

Assuming that the spring is linear elastic and the mass is zero, the propagation direction of the wave is assumed to be the positive direction of the $X$ axis. Under the action of the linear wave, the main form of movement of the buoy is the movement along the $X$ axis, the movement along the $Z$ axis and the rotation around the $Y$ axis. Therefore, three generalized coordinates should be used to describe the movement of the buoy.

$$q = [q_1, q_2, q_3] = [x, z, \beta]^T$$  \hspace{1cm} (13)$$

Assuming that the mass of the linear motor is small, the kinetic energy of the system is mainly produced by the buoy. The kinetic energy of the buoy includes translational kinetic energy and rotational kinetic energy, and its expression is as follows:

$$T_k = \frac{1}{2} q^T M q$$  \hspace{1cm} (14)$$

The potential energy of the system is:

$$U = \frac{1}{2} \rho g A_v q_2^2 + \frac{1}{2} C q_2^2 + \frac{1}{2} \sum_{i=1}^{n} K_i (L_i - L_{ni})^2$$  \hspace{1cm} (15)$$

Considering the fluid damping, the non-conservative generalized force on the system is:

$$Q_k = \begin{bmatrix} -b_{x} \dot{q}_1 \\ F_{x}(\cos(\omega t) - b_x + b_{xv}) \dot{q}_2 \\ M_{x}(\cos(\omega t) - b_x + b_{xv}) \dot{q}_2 \\ M_{x}(\cos(\omega t) - b_x + b_{xv}) \end{bmatrix}$$  \hspace{1cm} (16)$$

Substituting equations (15), (16) and (17) into equation (12), the dynamic model of the system can be obtained as:

$$M q + B \cdot \dot{q} + G = F$$  \hspace{1cm} (18)$$

The elements in matrix $G$ are as follows:

$$G_i = \frac{\partial U}{\partial q_i} = 2K \left[ 1 - L_0 \left( q_i - \frac{L \cos q_i}{2} \right)^2 \right]$$

$$+ \left( q_i - \frac{L \cos q_i}{2} \right)^2 - \frac{L^2}{2}$$

$$G_{11} = \frac{\partial U}{\partial q_1} = 2K \left[ 1 - L_0 \left( \frac{L \cos q_1}{2} \right)^2 \right]$$

$$+ \left( \frac{L \cos q_1}{2} \right)^2 - \frac{L^2}{2}$$

$$G_{22} = \frac{\partial U}{\partial q_2} = 2K \left[ 1 - L_0 \left( \frac{L \cos q_2}{2} \right)^2 \right]$$

$$+ \left( \frac{L \cos q_2}{2} \right)^2 - \frac{L^2}{2}$$

$$G_{33} = \frac{\partial U}{\partial q_3} = 2K \left[ 1 - L_0 \left( \frac{L \cos q_3}{2} \right)^2 \right]$$

$$+ \left( \frac{L \cos q_3}{2} \right)^2 - \frac{L^2}{2}$$

$$G_{44} = \frac{\partial U}{\partial q_4} = 2K \left[ 1 - L_0 \left( \frac{L \cos q_4}{2} \right)^2 \right]$$

$$+ \left( \frac{L \cos q_4}{2} \right)^2 - \frac{L^2}{2}$$

The elements in matrix $B$ are as follows:

$$B_{x} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

The elements in matrix $F$ are as follows:

$$F_{x} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$
4 Numerical examples

4.1 Wavelength solution steps

Equation (18) describes the dynamic model of the 3-SPS wave energy conversion device. It can be seen that, to analyze its dynamic characteristics, the parameters of the wave must first be calculated. The fixed-point iteration method is used to calculate the wavelength of linear waves. The main steps are as follows:

Step 1: Given the accuracy $\varepsilon$, the linear wave period $T$ and the distance from the static water surface to the seabed $h$.

Step 2: Given the initial iteration value $\lambda(0)$ of wavelength.

Step 3: Calculate $F_{s}(\lambda) = \frac{2^{1/2}}{\lambda} \tan\left(\frac{2\pi h}{\lambda}\right)$.

Step 4: If $|F_{s}(\lambda) - F_{s}(\lambda)| \geq \varepsilon$ set $\lambda = F_{s}(\lambda)$, repeat step 3.

Step 5: If $|F_{s}(\lambda) - F_{s}(\lambda)| \leq \varepsilon$, output $\lambda$.

Step 6: End.

4.2 Hydrodynamic analysis of 3-SPS wave energy conversion device

Supposing the wave height $H$ is 0.2 m, the period $T$ is 6 s, and the water depth is 100 m. The size of the buoy is selected as: $L = 1$ m, $D = 0.1$ m, $d = 0.05$ m. The parameters of the spring are: $L_{0} = 4$ m, $K = 10$ m. First, we calculated the value of each coefficient in equation (18).

Table 1. Values of the coefficients in formula (18)

| Coefficient | Value | Unit |
|-------------|-------|------|
| m           | 51.50 | kg   |
| $a_{wy}$    | 2.02  | kg   |
| $a_{wz}$    | 454.19| kg   |
| $A_{w}$     | 15.03 | kg·m²|
| $I_{x}$     | 4.33  | Kg·m²|
| $C$         | 849.58| N·m/rad|
| $b_{xz}$    | 1065.50| N·s/m |
| $b_{x3}$    | 88.79 | N·m/s-rad |
| $b_{xz}$    | 114.91| N·s/m |
| $b_{xz}$    | 114.91| N·s/m |
| $b_{pz}$    | 0     | N·s/m |
| $A_{wp}$    | 1     | M²   |
| $F_{z0}$    | 2012.10| N    |
| $M_{00}$    | 18.77 | N·m  |
| $a_{z}$     | 0     | rad  |

Solving equation (18) based on Runge-Kutta method, the movement rules of the moving platform along $X$, $Y$, and $Z$ axis and rotation around $Y$ axis can be obtained, as shown in Figure 3-5.
Figure 6 The generating power of 3-SPS wave energy conversion device

It can be seen from Figure 6 that the power generation of the 3-SPS wave energy conversion device is 0.186 kW. Based on equation (11), the linear wave power is 0.236kW, and the power generation efficiency of the 3-SPS wave energy conversion device is 78.76%.

5 Conclusion

This paper proposed a new type of 3-SPS wave energy conversion device. First, a linear wave kinematics model was derived. On this basis, a hydrodynamic model of the 3-SPS wave energy conversion device under the action of linear waves was established. This hydrodynamic model needs to consider the mutual coupling between rigid body dynamics and fluid dynamics. Based on the Runge-Kutta method, the hydrodynamic model of the 3-SPS wave energy conversion device was solved, and the utilization rate of the wave energy by the system was analyzed. The research results show that under the action of linear waves, the moving platform of the 3-SPS energy harvester has a certain speed along the surging direction at the initial stage of movement. When the system is stable, the translational kinetic energy in the surging direction gradually decays to zero. The wave energy captured by the buoy is mainly transformed into translational kinetic energy in the heaving direction and rotational kinetic energy in the pitching direction of the buoy. The wave energy utilization rate of the 3-SPS wave energy conversion device can reach 78.76%.
