A Vertex Operator Algebra Construction of the Colour-Kinematics Dual numerator

Chih-Hao Fu, Pierre Vanhove and Yihong Wang

Abstract: We derive a vertex operator based expression for the kinematic numerators of Yang-Mills amplitudes by applying the momentum kernel formalism to open string amplitudes. The expression involves an $\alpha'$-weighted commutator induced by the monodromy relations between the colour ordered Yang-Mills amplitudes, which mirrors the $\alpha'$ deformed colour structure observed in open string and semi-abelian $\mathbb{Z}$-theory. The kinematic algebra given by this construction contains the Lie algebra of diffeomorphism as an obvious sub-algebra.

Keywords: Scattering Amplitudes, String Monodromy, Colour-Kinematics Duality
1 Introduction

The discovery of colour-kinematics duality [1, 2] has led to numerous insights in the nature of gauge theory, gravity theory and their relations. Assuming a cubic graph representation of a Feynman diagram the colour-kinematic duality states that the kinematics numerators satisfy the same algebraic relations as the colour factor associated with the same diagram. At tree-level this duality implies kinematic relations between colour ordered amplitudes in gauge theory [1] which have been proven for tree-level graphs using string theory methods [3, 4] or quantum field theory techniques [5–8]. This duality provides a simple and powerful rule for constructing gravity amplitudes from gauge theory amplitudes by replacing colour factors with dual kinematics factors [2, 9]. At tree-level the double copy procedure has been proven [6, 7], and shown to be equivalent to the Kawai-Llewellyn-Tye (KLT) relations [10] between closed string and open string amplitudes [11]. This duality has been used in constructing higher-loop amplitudes in various supergravity theories [12–24], and a host of quantum field theories [25–32]. At five-loop order a generalised double copy method allowed to pin down the critical ultraviolet behaviour of the four-graviton amplitude in maximal supergravity [33, 34]. Such generalised Jacobi-like relations arise from the most general solution of
the monodromy relations between the colour ordered gauge theory amplitudes [35]. Assuming the validity of the colour kinematic duality to all loop orders one can derive the critical ultraviolet behaviour of the four-graviton amplitude in maximal supergravity [36]. This strengthens the idea of an underlying principle responsible for the colour kinematic duality. Another piece of evidence supporting this idea is that the Lie algebra of diffeomorphism has been identified to give rise to the kinematic numerators at least for special helicity configurations and for small multiplicity in [37–40].

A clue that may help to solve our above puzzle comes from a property of CFT known to the quantum groups community. It is known that a CFT, can be used to build not only a Lie algebra, but a much richer-structure Hopf algebra [41]. Indeed, as a matter of fact a similar argument was used in [42] to build the global $E_8 \times E_8$ symmetry generators of the heterotic string when kinematic restrictions were imposed due to the compactification condition. Considering the relation to heterotic string theory and to its $\mathcal{N} = 4$ supersymmetric version at tree level, we feel it is reasonable to suspect that certain weaker version of the Hopf algebraic structure survives in Yang-Mills, possibly related to the Drinfeld double structure observed earlier at four points [40].

In this paper we carry the spirit discussed above one step further and investigate the Jacobi-like relations between Yang-Mills kinematic numerators from $\alpha'$ limit of the open string amplitudes. We show at least from string perspective there is genuinely a natural cubic graph description of the scattering amplitude derived from the vertex operator algebra that when reaching the $\alpha' \to 0$ limit satisfies the anti-symmetry and Jacobi identities assumed by the BCJ duality. In particular we find a half-ladder basis numerator are given by the following simple expression

$$n(123\ldots n) = \lim_{k_2,\alpha' \to 0} \langle f|[[[T_1, T_2]_{\alpha'}, T_3]_{\alpha'} , \ldots , T_{n-1}]_{\alpha'} |0\rangle,$$

where where $|f\rangle$ is the modified external state defined in (3.6) and the generators $T_i$ here are vertex operators, being properly analytic continued and integrated, $T_i = \int_0^1 dz V_i(z)/z$, and $[ , ]_{\alpha'}$ is the $\alpha'$-weighted commutator

$$[T_1, T_2]_{\alpha'} = T_1 T_2 - e^{-i\pi\alpha' k_2 \cdot k_1} T_2 T_1$$

originally introduced in [43] to express the string theory generalization of the Del Duca-Dixon-Maltoni [44] colour decomposition of Yang-Mills amplitude

$$\mathcal{M}_n^{\text{open}} = \sum_{\sigma \in S_{n-2}} tr([[t_1, t_{\sigma(2)}]_{\alpha'}, t_{\sigma(3)}]_{\alpha'}, \ldots , t_{\sigma(n-1)}]_{\alpha'} t_n) A_n(1, \sigma(2), \ldots, \sigma(n-1), n)$$

derived from string monodromy relation, and recently again observed in semi-abelian $Z$-theory in [45]. The construction of this paper is will use bosonic string theory, but the discussion generalises easily to the superstring case. In fact similar structures have been obtained in [46] using the pure spinor formalism in open string theory. The construction of this paper gives a kinematic analogue of the colour traces in (1.3) and provides an alternative construction to the kinematic traces of [47]. From a string perspective this answers the question raised earlier above as to why the product of momentum kernel with colour-ordered
amplitude should possess algebraic properties. In addition we identify the Lie algebra of diffeomorphism as the vector × vector → vector part of the sub-algebra, while the full numerator is restored when scalar and tensor contributions are included. The kinematic algebra obtained as the field theory limit of vertex operator algebra in this paper however has the apparent drawback of being lack of simplicity. At the moment it is not completely clear to us whether a wiser representation exists or the algebraic expression is of any practical use. We hope that perhaps its analytic feature can be taken as a useful reference when constructing numerator ansatz at higher loop orders. The vertex algebra based numerators (1.1) derived in this paper demonstrate another formal symmetry between the colour and kinematic factors of the string amplitude, in an expression that is even closer to the field theory double copy structure.

This paper is organised as follows. In section 2 we briefly review a few analytic features of the string KLT monodromy relations, especially the monodromy related properties presented in [11], which will prove very much useful in our later discussions. We next introduce in section 3 a specific off-shell continuation of the open string amplitude that will serve our purpose of deriving a vertex operator explanation. The relations between vertex operator algebra and BCJ numerators will be unravelled through two examples in sections 4.1 and 4.2, followed by a short discussion on the explicit form of the generators that appears in the numerator formula. In section 5.1 we reproduce the Lie algebra of diffeomorphism as a sub-algebra. In section 5.3 we will demonstrate generically what analytic structure appears in a string of structure constants at higher points and its relation to hypergeometric functions arising from disc integrals. We conclude the paper with a brief comment on our results and related problems in section 6.

2 Preliminaries

In this section we review a few details related to the string KLT monodromy relations that will become useful to our later derivations. It was demonstrated in [11] that when properly analytic continued, the world-sheet integral of a bosonic closed string amplitude factorises according to its dependence on light-cone
coordinates \( v_i^\pm = v_i^1 \pm v_i^2 \),

\[
\mathcal{M}_{n,\text{closed}} = \sum_{\alpha \in S_{n-3}} \mathcal{A}_n(1, \alpha, n-1, n) \mathcal{I}_\alpha, \tag{2.1}
\]

where the \( v^+ \) integrals together was identified as a colour-ordered bosonic open string amplitude \( \mathcal{A}_n \), and the \( v^- \) integrals together reads

\[
\mathcal{I}_{23\ldots n-1} = \int_{\Gamma_2} dv^-_2 \int_{\Gamma_3} dv^-_3 \cdots \int_{\Gamma_{n-1}} dv^-_{n-1} \prod_{i=2}^{n-2} (v^-_i)^{\alpha'k_1k_2(1-v^-_2)^{\alpha'k_{n-1}k_2}} \prod_{i<j} (v^-_i - v^-_j)^{\alpha'k_jk_2} f(v^-_2), \tag{2.2}
\]

where \( f(v^-_i) \) arises from the operator product expansion of the vertex operators. The integration contours \( \Gamma_2, \Gamma_3, \ldots, \Gamma_{n-2} \) illustrated in Fig 1(a) were defined to avoid branch cuts due to factors \( (v^-_i - v^-_j)^{\alpha'k_jk_2} \), while variables \( (v^-_1, v^-_{n-1}, v^-_n) \) were gauge fixed by world-sheet Moebius invariance to be \((0, 1, \infty)\) respectively. These contours were then pulled to the left, assuming no pole lying in the lower half plane. The result is to replace \( \Gamma_2, \ldots, \Gamma_{n-2} \) by a new set of contours defined along the branch cut \([0, -\infty)\) (Fig 1(b)). It was noted that the phase difference between the two sides of the branch cut \([0, -\infty)\) in the \( C_2 \) integration produces an overall sine factor,

\[
\int_{C_2} dv^-_2 (v^-_2)^{\alpha'k_1k_2(1-v^-_2)^{\alpha'k_{n-1}k_2}} \prod_{j=3}^{n-2} (v^-_j - v^-_2)^{\alpha'k_jk_2} f(v^-_2) = 2i \sin(\pi \alpha'k_1 \cdot k_2) \int_{-\infty}^{0} dv^-_2 (-v^-_2)^{\alpha'k_1k_2(1-v^-_2)^{\alpha'k_{n-1}k_2}} \prod_{j=3}^{n-2} (v^-_j - v^-_2)^{\alpha'k_jk_2} f(v^-_2), \tag{2.3}
\]

and similarly for the contour \( C_3 \)

\[
\int_{C_3} dv^-_3 (v^-_3)^{\alpha'k_1k_3(1-v^-_3)^{\alpha'k_{n-1}k_3}} \prod_{j=4}^{n-2} (v^-_j - v^-_3)^{\alpha'k_jk_3} f(v^-_3) = 2i \sin(\pi \alpha'k_1 \cdot k_3) \int_{0}^{v^-_2} dv^-_3 (-v^-_3)^{\alpha'k_1k_3(1-v^-_3)^{\alpha'k_{n-1}k_3}} \prod_{j=4}^{n-2} (v^-_j - v^-_3)^{\alpha'k_jk_3} f(v^-_3) + 2i \sin(\pi \alpha'(k_1 + k_3) \cdot k_3) \int_{-\infty}^{v^-_2} dv^-_3 (-v^-_3)^{\alpha'k_1k_3(1-v^-_3)^{\alpha'k_{n-1}k_3}} \prod_{j=4}^{n-2} (v^-_j - v^-_3)^{\alpha'k_jk_3} f(v^-_3). \tag{2.4}
\]

Repeating the same manipulation on all contours led to the extraction of a momentum kernel, and the remaining factor was identified as another copy of the bosonic open string amplitude \( \tilde{\mathcal{A}}_n \),

\[
\mathcal{I}_{23\ldots n-1} = \sum_{\beta \in S_{n-3}} S_{\alpha'\beta} [n-1, \ldots, 4, 3, 2[\beta] \tilde{\mathcal{A}}_n(n-1, n, \beta, 1), \tag{2.5}
\]
where the momentum kernel \( S_{\alpha'}[i_2, \ldots, i_k, j_2, \ldots, j_k]_p \) in the context of string theory is defined as\(^1\)

\[
S_{\alpha'}[i_1, \ldots, i_k, j_1, \ldots, j_k]_p \equiv (\pi \alpha'/2)^{-k} \int \prod_{t=1}^{k} \sin(\pi \alpha'(p \cdot k_i + \sum_{q>t} \theta(i_t, i_q) k_{i_t} \cdot k_{i_q})),
\]

where \( \theta(i_t, i_q) = 1 \) if the ordering of \( i_t \) and \( i_q \) is the opposite in the \( \{i_1, \ldots, i_k\} \) and \( \{j_1, \ldots, j_k\} \) and otherwise 0 if the ordering is the same. This expression becomes identical to the field theory momentum kernel \([6]\) in the \( \alpha' \to 0 \) limit

\[
S[i_1, \ldots, i_k,j_1, \ldots, j_k]_p = \prod_{t=1}^{k} (p \cdot k_i + \sum_{q>t} \theta(i_t, i_q) k_{i_t} \cdot k_{i_q}).
\]

In the literature of colour-kinematics duality, it was realised that the momentum kernel relations described above offers a convenient solution to the kinematic numerators \([9, 35]\). This is because if we treat the gravity amplitude as double copies and leave one copy of the Yang-Mills amplitude as it is, the other copy combines with the momentum kernel, which is understood to be the inverse of the propagator matrix, and produces a \( (n-2)! \)-basis half ladder numerator \( n(1\alpha n) \) associated with that copy of the amplitude. The result is the familiar Del Duca-Dixon-Maltoni expression,

\[
\mathcal{M}_n^{\text{closed}} = \sum_{\alpha \in S_{n-2}} \mathcal{A}_n(1, \alpha, n) n(1\alpha n).
\]

Comparing equation (2.8) with its string theory analogue (2.1), it is natural to conclude that the \( v^- \) integral \( I_\alpha \) becomes the basis numerator \( n(1\alpha n) \) in the \( \alpha' \) limit. One can express the half ladder numerator using the momentum kernel \([11]\) as

\[
n(1, \gamma(2), \gamma(3), \ldots, \gamma(n-1), n) = \begin{cases} \sum_{\beta \in S_{n-3}} S[\gamma^T | \beta] \tilde{A}_n(1, \beta, n, n-1), & \gamma(n-1) = n-1 \\ 0 & \gamma(n-1) \neq n-1. \end{cases}
\]

These numerators are not unique as any shifts proportional to the momentum kernel will not change the total amplitude (2.8). These numerators are not always local and can present poles \([9]\) but the total amplitude is always local. These non-localities are sometime useful in finding a colour-kinematic representation of gauge theories amplitudes \([48]\), which is consistent with (2.5). The above prescription however has the apparent shortcoming that not all of its legs are treated on equal footing (which could be regarded as the result of a generalised gauge shift on the numerators) making it difficult to allow algebraic interpretation. It is also know that when applied to amplitudes that has an algebraic structure by construction such as those of the \( \phi^3 \) theory, a \( (n-3)! \) minimal KLT basis (2.9) yields shifted numerators rather than the expected string of structure constant \( f^{abc} f^{scs} f^{sd} \cdots \). In view of these a slight modification to this approach was added in \([49, 50]\) where the numerators were solved in a more symmetric \( (n-2)! \) basis

\[
n(1, \gamma(2), \gamma(3), \ldots, \gamma(n-1), n) = \lim_{k_n^2 \to 0} \sum_{\beta \in S_{n-2}} \frac{1}{k_n^2} S[\gamma^T | \beta] \tilde{A}_n(1, \beta, n),
\]

\(^1\) Thanks to the factorisation property \([11, \text{eq } (3.2)]\) the momentum kernel enjoys a nice recursive definition \([32, \text{eq.} (2.7)]\).

\(^2\) This can be easily verified, for example by a straightforward calculation at four points.
at the cost that one of the legs must be taken off-shell until the end of the calculation in order to keep a \((n-2)!\) basis momentum kernel matrix non-singular.

In the following sections we derive the kinematic algebra from string perspective using similar reasoning to that described above, except backwards. Starting with a \((n-2)!\) basis prescription for kinematic numerator (2.10), we translate the factors of sine introduced by momentum kernel as world-sheet integrals along two sides of a branch cut. (In light of the fact that a \((n-2)!\) basis prescription does lead to unshifted numerator for \(\phi^3\) theory.) For this purpose an off-shell continuation to the string amplitude is introduced. As we shall see, the numerator thus defined does have a natural algebraic explanation.

3 An off-shell continuation of the open string amplitude

For the purpose of discussion we recall that an \(n\)-point bosonic open string amplitude is defined in the operator language as

\[
A_n = \alpha'^{n-3} g^{n-2} \left\langle f \big| V_{n-1}(1) \frac{1}{L_0 - I} V_{n-2}(1) \cdots V_3(1) \frac{1}{L_0 - I} V_2(1) \big| i \right\rangle, \tag{3.1}
\]

where the external states are \(|f\) = \(\lim_{z_n \to \infty} z_n V(z_n)|0\rangle\) and \(|i\) = \(\lim_{z_1 \to 0} z_1^{-1} V(z_1)|0\rangle\) acting on the vacuum \(|0\rangle\). In standard calculation \([42]\) the propagators are replaced by integrals \(\frac{1}{L_0 - I} = \int_0^1 dz \, z^{L_0-2}\), yielding

\[
A_n = \alpha'^{n-3} g^{n-2} \int_0^1 \frac{dz_n}{z_n} \cdots \int_0^1 \frac{dz_3}{z_3} \int_0^1 \frac{dz_2}{z_2} \left\langle f \big| V_{n-1}(1) z_n^{-L_0-2} V_{n-2}(1) z_n^{-L_0-2} V_{n-3}(1) \cdots z_3^{-L_0-2} V_3(1) z_2^{-L_0-2} V_2(1) \big| i \right\rangle
\]

\[
= \alpha'^{n-3} g^{n-2} \int_0^1 \frac{dz_n}{z_n} \cdots \int_0^1 \frac{dz_3}{z_3} \int_0^1 \frac{dz_2}{z_2} \left\langle f \big| V_{n-1}(1) \left( z_n^{-L_0-2} V_{n-2}(1) z_n^{-L_0-2} \right) \right\rangle
\]

\[
\times \left( (z_n^{-2} z_n^{-2})^{L_0-1} V_{n-1}(1)(z_n^{-2} z_n^{-2})^{-(L_0-1)} \right) \cdots \left( (z_3 z_4 \cdots z_n^{-2})^{L_0-1} V_3(1)(z_3 z_4 \cdots z_n^{-2})^{-(L_0-1)} \right)
\]

\[
\times \left( (z_2 z_3 \cdots z_{n-2})^{L_0-1} V_2(1)(z_2 z_3 \cdots z_{n-2})^{-(L_0-1)} \right) \big| i \right\rangle, \tag{3.2}
\]

where in the second line above we simultaneously multiplied and divided by factors of \(z_i^{-L_0-1}\) between vertex operators. The familiar Veneziano type world-sheet integral formula is then obtained via a change of integration variables to

\[
y_2 \equiv z_2 z_3 z_4 \cdots z_{n-2}
\]

\[
y_3 \equiv z_3 z_4 \cdots z_{n-2}
\]

\[
\vdots
\]

\[
y_{n-2} \equiv z_{n-2}
\]

\[
\tag{3.3}
\]
and using the fact that vertex operators are primary fields of conformal dimension one, \( V(y) = y^{L_0 - 1} V(1) y^{-(L_0 - 1)} \),

\[
A_n(123 \ldots n) = \alpha'^{-3} g^{n-2} \int_{0 < y_2 < y_3 < \ldots < y_{n-2} < 1} d y_i \left( f \right| V_{n-1}(1) \frac{V_{n-2}(y_{n-2})}{y_{n-2}} \ldots \frac{V_3(y_3)}{y_3} \frac{V_2(y_2)}{y_2} \left| i \right) \tag{3.4}
\]

\[
= \alpha'^{-3} g^{n-2} \int_{0 < y_2 < y_3 < \ldots < y_{n-2} < 1} d y_i \left( y_2^\alpha' k_2 k_1 (1 - y_2) \alpha' k_2 k_{n-1} \prod_{i < j < n-2} (y_j - y_i)^{\alpha' k_j k_i} f(y_i) \right),
\]

where \( f(y_i) \) arises from the operator product expansion of the vertex operators. The integration domain changes as a result to \( 0 < y_2 < y_3 < \ldots < y_{n-2} < 1 \).

Instead of equation (3.1), we consider a similar formula ended however with an off-shell final state,

\[
J_n(123 \ldots n) \equiv \alpha'^{-3} g^{n-2} \frac{1}{k_n^2} \left( f \right| V_{n-1}(1) \frac{1}{L_0 - I} V_{n-2}(1) \ldots \frac{1}{L_0 - I} V_2(1) \left| i \right) \tag{3.5}
\]

\[
= \alpha'^{-2} g^{n-2} \left( f \right| \frac{1}{L_0 - I} V_{n-1}(1) \frac{1}{L_0 - I} V_{n-2}(1) \ldots \frac{1}{L_0 - I} V_2(1) \left| i \right) .
\]

where the off-shell continuation is defined through BCFW-like shifting \( \hat{k}_n = k_n + \epsilon q \) and \( \hat{k}_1 = k_1 - \epsilon q \), with the shifting chosen such that \( q \cdot k_1 = 0 \) while \( q \cdot k_n \neq 0 \), and the initial and final states are defined as

\[
\left| \gamma \right) \equiv \epsilon_1 \alpha_{-1} e^{i(k_1 - \epsilon q) \cdot x} \left| 0 \right) \tag{3.6}
\]

\[
\left| \hat{\gamma} \right) \equiv \epsilon_n \alpha_{-1} e^{i(k_n + \epsilon q) \cdot x} \left| 0 \right) .
\]

The same off-shell continuation was introduced earlier in field theory amplitudes in [51] to define KLT monodromy relations in a \((n - 2)!\) basis. Note that this is different from how the off-shell continuation would usually be defined on string amplitudes [52, 53], since conformal symmetry is respected by vertex operators only when on-shell, and it makes little sense to define a vertex operator if we are not allowed to shrink the external leg to a point via conformal transformation in the first place. Nevertheless it is apparent that apart from an overall \( 1/k_n^2 \), equation (3.5) formally agrees with the amplitude (3.1) in the on-shell limit. In this sense equation (3.5) is a string analogue of the off-shell current. As in the standard amplitude calculation discussed above we then replace all propagators, including the newly introduced one by the off-shell leg, and write

\[
J_n(123 \ldots n) = \alpha'^{-3} g^{n-2} \int_0^1 d z_{n-1} \ldots \int_0^1 d z_3 \int_0^1 d z_2 \left( f \right| \left( z_{n-1}^{L_0 - 1} V_{n-1}(1) z_{n-1}^{-(L_0 - 1)} \right) \left( z_{n-2}^{L_0 - 1} V_{n-2}(1) z_{n-2}^{-(L_0 - 1)} \right) \ldots \left( z_3^{L_0 - 1} V_3(1) z_3^{-(L_0 - 1)} \right) \left( z_2^{L_0 - 1} V_2(1) z_2^{-(L_0 - 1)} \right) \left| i \right) \tag{3.7}
\]
A similar change of variables

\[ y_2 \equiv z_2 z_3 z_4 \ldots z_{n-1} \]
\[ y_3 \equiv z_3 z_4 \ldots z_{n-1} \]
\[ \vdots \]
\[ y_{n-2} \equiv z_{n-2} z_{n-1} \]
\[ y_{n-1} \equiv z_{n-1} \],

this time leads to \((n - 2)\) instead of \((n - 3)\) vertex operators to be integrated between \((0, 1)\),

\[ \mathcal{J}_{n}(123 \ldots n) = \alpha^{m-2} g^{n-2} \int_{[0,y_2<y_3<\ldots<y_{n-1}<1]} \prod_{i=2}^{n-2} dy_i \left\langle \hat{f} \left[ V_{n-1}(1) \frac{V_{n-2}(y_{n-2})}{y_{n-2}} \ldots \frac{V_{3}(y_3)}{y_3} \frac{V_{2}(y_2)}{y_2} \right] \right\rangle. \]  

(3.9)

As discussed earlier in this paper, in light of the fact that field theory momentum kernel happens to be the inverse of propagator matrix in a \((n - 2)!\) basis, the (field theory) numerator can be calculated from the \(\alpha'\) limit of the following sum over \((n - 2)!\) permutations of the legs \(\{2, 3, 4, \ldots, n - 1\}\),

\[ n(123 \ldots n) = \lim_{k_2^2,\alpha' \to 0} \sum_{\beta \in S_{n-2}} S_{\alpha'[n - 1, \ldots, 4, 3, 2|\beta]} \mathcal{J}_{n}(1, \beta, n). \]  

(3.10)

Despite perhaps a bit complicated at first sight, it is known [50, 54] that the above permutation sum very often simplifies if we organise the amplitudes (or currents) in the equation according the so-called Fundamental BCJ relations [3–5],

\[
\lim_{k_2^2,\alpha' \to 0} \sum_{\beta \in S_{n-3}} S_{\alpha'[n - 2, \ldots, 4, 3, 2|\beta]} \left\{ \sin(\pi \alpha' k_{n-1} \cdot k_1) \mathcal{J}_{n}(1, n - 1, \beta_2, \beta_3, \ldots, \beta_{n-2}, n) \\
+ \sin(\pi \alpha' k_{n-1} \cdot (k_1 + k_2)) \mathcal{J}_{n}(1, \beta_2, n - 1, \beta_3, \ldots, \beta_{n-2}, n) \\
+ \ldots \\
+ \sin(\pi \alpha' k_{n-1} \cdot (k_1 + k_2 + \cdots + k_{n-2})) \mathcal{J}_{n}(1, \beta_2, \beta_3, \ldots, \beta_{n-2}, n - 1, n) \right\}. 
\]

(3.11)

Explicitly we focus first on the subset of the full \((n - 2)!\) permutation sum in equation (3.10) where leg \((n - 1)\) is inserted between the relatively fixed set \(\{2, 3, 4, \ldots, n - 2\}\). It is straightforward to see from the definition of momentum kernel that this is proportional to

\[
\sin(\pi \alpha' k_{n-1} \cdot k_1) \mathcal{J}_{n}(1, n - 1, 2, 3, \ldots, n - 2, n) + \sin(\pi \alpha' k_{n-1} \cdot (k_1 + k_2)) \mathcal{J}_{n}(1, 2, n - 1, 3, \ldots, n - 2, n) + \ldots + \sin(\pi \alpha' k_{n-1} \cdot (k_1 + k_2 + \cdots + k_{n-2})) \mathcal{J}_{n}(1, 2, 3, \ldots, n - 2, n - 1, n).
\]

(3.12)

To complete this calculation we then perform a \((n - 3)!\) permutation sum on the originally fixed set \(\{2, 3, 4, \ldots, n - 2\}\), which in turn can be organised into BCJ sums if we regard it as insertions of the leg.
(n−2) between set {2, 3, 4, ..., n−3} and so on. We will see in the next section that algebraic structure can be identified in this process. We shall also drop the distinction between \(|f\rangle\) and \(|\tilde{f}\rangle\) since it is known that at least in the field theory limit, numerators obtained through equation (2.10) remain finite in the on-shell limit.

4 Half-ladder basis numerators and the vertex operator algebra

The BCJ sum (3.12) written down in the last section can be more easily understood in the language of vertex operators. We will in the following illustrate this idea through two lower-point examples. For simplicity we will assume the scattering particles are all tachyons, although the generalisation to gluons is straightforward.

4.1 The three point numerator

Consider the numerator at three points. Equation (3.10) reads

\[
2i \sin(\pi \alpha' k_2 \cdot k_1) \int_0^1 \frac{dy_2}{y_2} y^{\alpha' k_2 \cdot k_1} = \int_{\gamma_2^+ - \gamma_2^-} \frac{dy_2}{y_2} (-y_2)^{\alpha' k_2 \cdot k_1},
\]  

(4.1)

where we followed the same reasoning used in the extraction of string momentum kernel from monodromy relations [11] to translate the sine factor into the difference between integrals \(\gamma_2^+\) and \(\gamma_2^-\) along opposite sides of a branch cut (Fig 4.1). To see how equation (4.1) can possibly have an algebraic origin, recall that in the operator language a Veneziano type world-sheet integral formula derives from normal ordering two vertex operators

\[
V(y_1)V(y_2) = (e^{\sqrt{\alpha'} \sum_1^{\infty} \frac{k_1 \cdot x}{\alpha} y_1^n} e^{-\sqrt{\alpha'} \sum_1^{\infty} \frac{k_2 \cdot x}{\alpha} y_2^{-n}} e^{ik_1 \cdot e^{k_2 \cdot p \ln y_1}}) \left( e^{\sqrt{\alpha'} \sum_1^{\infty} \frac{k_2 \cdot x}{\alpha} y_2^n} e^{-\sqrt{\alpha'} \sum_1^{\infty} \frac{k_2 \cdot x}{\alpha} y_2^{-n}} e^{ik_2 \cdot e^{k_2 \cdot p \ln y_2}} \right)
\]

\[
= e^{\alpha' k_1 \cdot k_2 \ln y_1} e^{-\alpha' \sum_1^{\infty} \frac{k_2 \cdot x}{\alpha} \frac{y_2^n}{y_1^n}} : V(y_1)V(y_2) : 
\]

\[
\sim e^{\alpha' k_1 \cdot k_2 \ln(y_2-y_1)} f(y).
\]  

(4.2)

Starting from a point \(y_2\) on the real line with \(1 - \frac{y_2}{y_1} > 0\) so that the infinite series converges \(\sum_1^{\infty} \frac{1}{n} \left( \frac{y_2}{y_1} \right)^n = \ln(1 - \frac{y_2}{y_1})\), the analytic continuation of the product \(V(y_1)V(y_2) \sim e^{\alpha' k_1 \cdot k_2 \ln(y_2-y_1)} f(y)\) is uniquely determined as \(y_2\) travels continuously on the complex plane. Bearing this in mind, it is straightforward to see
that integration contour associated with the ordered product

\[ \frac{V(y_1)}{y_1} \left( \int_0^1 dy_2 \frac{V(y_2)}{y_2} \right), \tag{4.3} \]

analytically continues as illustrated in Fig 3(a), while the contour associated with opposite order

\[ \left( \int_0^1 dy_2 \frac{V(y_2)}{y_2} \right) \frac{V(y_1)}{y_1}, \tag{4.4} \]

corresponds to Fig 3(b). (In the later case \( V(y_2)V(y_1) \sim e^{\alpha y_1} k_1 \ln(y_2-y_1) f(y) \) and the branch cut lies along the \( y_2 < y_1 \) part of the real line.)

A careful inspection on the three-point numerator obtained earlier in (4.1) then shows that the numerator can be written in the operator language as

\[
\int_{\gamma_2^1} \frac{dy_2}{y_2} \left( -y_2 \right)^{\alpha' k_2-k_1} \cdot e^{-i\pi \alpha' k_2, k_1} \int_{\gamma_2^2} \frac{dy_2}{y_2} \left( -y_2 \right)^{\alpha' k_2-k_1} \\
= \left( \int_0^1 dy_2 \left( f \left[ \frac{V_1(y_1)}{y_1}, \frac{V_2(y_2)}{y_2} \right] 0 \right) - e^{-i\pi \alpha' k_2, k_1} \int_0^1 dy_2 \left( f \left[ \frac{V_2(y_2)}{y_2} \frac{V_1(y_1)}{y_1} \right] 0 \right) \right) \bigg|_{y_1 \to 0} \\
= \langle f | [T_1, T_2]_{\alpha'} | 0 \rangle, \tag{4.5} \]

where \( \langle f | \) is the external state defined (3.6) for \( n = 3 \). This is in some sense the structure we anticipated. However instead of a Lie bracket, we arrive at a similar, yet asymmetric structure defined as\(^4\)

\[
[T_1, T_2]_{\alpha'} = T_1 T_2 - e^{-i\pi \alpha' k_2, k_1} T_2 T_1 \tag{4.7} \]

\(^3\)Here we are assuming all the \( y_i \)'s were shifted initially in the imaginary direction \( y_i \to y_i + i\epsilon \delta_i \) as in \([11]\) prior to the analytic continuation along the horizontal line \((0 + i\epsilon \delta_i, 1 + i\epsilon \delta_i)\), along which the integration is performed. The shifts \( \delta_i \) were defined according to the ordering of the vertex operators so that \( \delta_i < \delta_j \) if operator \( V_j \) appears on the right side of \( V_i \). The integration contours become those shown in Fig 3 when \( \delta \to 0 \).

\(^4\)The bracket observed here can be identified as a weakly closed system. Given an associative algebra \( \mathbb{A} \) over some field \( F \), a weakly closed system is the closed set of elements under an additional multiplicative operation (bracket) \( \times : \mathbb{A} \otimes \mathbb{A} \to \mathbb{A} \) of the form

\[ a \times b = ab + \gamma(a, b) ba \tag{4.6} \]

For some \( \gamma(a, b) \in F \). In principle it is actually possible to restore Lie brackets by introducing co-cycles similar to those discussed in \([42, \text{section 6.4}]\). In this picture additional order dependent exponential factors factorise from the numerator.
where we introduced the shorthand notation to denote $T_2 = \int_0^1 dy_2 \frac{V_2(y_2)}{y_2}$ and $T_1 = \frac{V_1(y_1)}{y_1} \bigg|_{y_1 \to 0}$.

### 4.2 Four points and higher

The numerator at four points follows similar calculations. As discussed earlier we note that BCJ sums can be extracted from the full $(n-2)!$ permutation sum appears in (3.10).

$$
2i \sin(\pi \alpha' k_3 \cdot k_1) J_4(1324) + 2i \sin(\pi \alpha' k_3 \cdot (k_1 + k_2)) J_4(1234)
$$

$$= 2i \sin(\pi \alpha' k_3 \cdot k_1) \int_0^{y_2} \frac{dy_3}{y_3} \alpha' k_3 - k_1 y_2 y_3 \alpha' k_3 - k_2 f(y_3)
$$

$$+ 2i \sin(\pi \alpha' k_3 \cdot (k_1 + k_2)) \int_{y_2}^1 \frac{dy_3}{y_3} \alpha' k_3 - k_1 y_3 - y_2 \alpha' k_3 - k_2 f(y_3)
$$

$$= \int_{\gamma_3^+ - \gamma_3^-} \frac{dy_3}{y_3} (-y_3) \alpha' k_3 - k_1 y_2 - y_3 \alpha' k_3 - k_2 f(y_3),
$$

(4.8)

where in the last line of the equation above we translated the phase factors introduced by sines into the difference between integrals $\gamma_3^+$ and $\gamma_3^-$ below and above the branch cut, similar to those illustrated in Fig 4.1. The first and the second term contribute the $0 < |y_3| < y_2$ and $y_2 < |y_3| < 1$ segment of the $\gamma_3^+$ contour respectively, and likewise for the contour $\gamma_3^-$. Equation (4.8) can be subsequently rewritten as

$$
\int_{\gamma_3^+} \frac{dy_3}{y_3} (-y_3) \alpha' k_3 - k_1 y_2 - y_3 \alpha' k_3 - k_2 f(y_3) - e^{i\pi \alpha' k_3 \cdot (k_1 + k_2)} \int_{\gamma_3^-} \frac{dy_3}{y_3} \alpha' k_3 - k_1 (y_3 - y_2) \alpha' k_3 - k_2 f(y_3)
$$

$$= \langle f \bigg| \frac{V(y_2)}{y_2} \frac{V(y_1)}{y_1} \left( \int_0^1 \frac{dy_3}{y_3} \frac{V(y_3)}{y_3} \right) |0\rangle - e^{i\pi \alpha' k_3 \cdot (k_1 + k_2)} \langle f \bigg| \left( \int_0^1 \frac{dy_3}{y_3} \frac{V(y_3)}{y_3} \right) \frac{V(y_2)}{y_2} \frac{V(y_1)}{y_1} |0\rangle,
$$

(4.9)

again here $\langle f |$ is the external state defined (3.6) for $n = 4$. What remains in the calculation is a multiplication by $2i \sin(\pi \alpha' k_2 \cdot k_1)$, which has the same effect as was shown at three points, and we arrive at

$$
n(1234) = \lim_{k_2^+ \alpha' \to 0} \langle f | [[T_1, T_2]_{\alpha'}, T_3]_{\alpha'} |0\rangle,
$$

(4.10)

where $T_2 = \int_0^1 dy_2 \frac{V_2(y_2)}{y_2}$, $T_3 = \int_0^1 dy_3 \frac{V_3(y_3)}{y_3}$, and $T_1 = \frac{V_1(y_1)}{y_1} \bigg|_{y_1 \to 0}$. Generically this translation procedure continues, and the $n$-point half-ladder basis numerator is given by

$$
n(123\ldots n) = \lim_{k_2^+ \alpha' \to 0} \langle f | [[T_1, T_2]_{\alpha'}, T_3]_{\alpha'} \ldots, T_{n-1}]_{\alpha'} |0\rangle.
$$

(4.11)

Incidentally the same $\alpha'$-weighted commutator structure was actually observed earlier in [43] from a rather different perspective, and more recently in [45]. There it was shown that, starting from the standard colour-order formulation and applying the Kleiss-Kuijf relations [55] on the colour-ordered open string amplitudes, the result is a formula bearing much resemblance to the Del Duca-Dixon-Maltoni expression,
except with the Lie bracket between the $SU(N)$ colour generators $t_a$ replaced by exactly the same $\alpha'$-weighted commutator (4.7).

$$M_n = \sum_{\rho \in S_{n-1}} \text{tr}(t_{\rho(1)} t_{\rho(2)} \cdots t_{\rho(n-1)} t_n) \mathcal{A}_n(\rho(1), \rho(2), \ldots, \rho(n-1), n)$$

$$= \sum_{\sigma \in S_{n-2}} \text{tr}([[t_1, t_{\sigma(2)}]_{\alpha'}, [t_{\sigma(3)}]_{\alpha'}, \ldots, [t_{\sigma(n-1)}]_{\alpha'} t_n]) \mathcal{A}_n(1, \sigma(2), \ldots, \sigma(n-1), n). \quad (4.12)$$

In this sense we see that the numerator structure (4.11) just derived serves as the colour-kinematics counterpart of (4.12) in the context of string theory.

Note that the asymmetry feature of the new bracket $[,]_{\alpha'}$ is entirely introduced by the phase factor $e^{-i\pi\alpha' k_1 \cdot k_2}$ which vanishes in the $\alpha' \to 0$ limit, so that as far as field theory is concerned, we might as well replace all bracket with Lie bracket in the (field theory) numerator formula. In the section 4.3 we will work out some explicit examples. The basis numerator $n(123 \ldots n)$ thus obtained apparently respects Jacobi identity. Under this setting, a generic (not necessarily half-ladder) numerator is then simply given by the commutator structure suggested by its associated cubic graph, for example

$$\sim [[T_1, T_2], [T_3, T_4]] \quad (4.13)$$

### 4.3 Explicit generators

Despite the apparent formal simplicity attained by expressing kinematic numerator in the language of vertex operator algebra, it is not yet clear to us whether the generator $T_a = \int_0^1 dy V(y) \frac{y}{y}$ has a simple representation so that the numerators can be calculated from the algebra directly. Instead in this section we carry out the integral term-wise. Hopefully the calculation can provide useful insight regarding to the analytic behaviour of the generators.

As an illustration of how this proceeds, for the moment we make a bit of digression and calculate the three-point numerator directly instead of calculating $T_a$, which takes the same generic form as far as the integral is concerned, except simpler. The four-point case requires the evaluation of the disc integral and will be treated in section 5.3. Taking into account that momentum kernel at three points is simply a sine factor, and that the current is given by equation (3.9), the numerator defined in (3.10) reads

$$n(123) = \lim_{k_3, \alpha' \to 0} \sin(\pi\alpha' k_2 \cdot k_1) \langle \hat{f} | : \int_0^1 dy_2 \frac{y_2}{y_2} \varepsilon_2 \cdot X(y_2) e^{ik_2 \cdot X} : | \hat{i} \rangle. \quad (4.14)$$
Plugging the explicit mode expansion of the vertex operator shows that the expectation value contributes the following integral.

\[
\langle \hat{f} \rangle = \int_0^1 \frac{dy_2}{y_2} \epsilon_2 \cdot X(y_2) e^{i k_2 \cdot X} \langle \hat{\gamma} \rangle = V_3 \int_0^1 \frac{dy_2}{y_2} e^{\alpha' k_2 \cdot k_1 \ln y_2},
\]

where \( V_3 \) is the Yang-Mills cubic

\[
V_3 = (\epsilon_2 \cdot \epsilon_1)(k_2 \cdot \epsilon_3) + (\epsilon_3 \cdot \epsilon_2)(k_2 \cdot \epsilon_1) + (\epsilon_3 \cdot \epsilon_1)(k_2 \cdot \epsilon_1).
\]

Namely in this case the world-sheet integral factorises, and gives

\[
\int_0^1 dy_2 (y_2)^{\alpha' k_2 \cdot k_1 - 1} = \frac{1}{\alpha' k_2 \cdot k_1}.
\]

The three-point current is therefore \( V_3/k_3^2 \) as expected. Multiplying current by momentum kernel \( \sin(\pi \alpha' k_2 \cdot k_1) \sim \pi \alpha' k_2 \cdot k_1 \) shows that the numerator is \( V_3 \) in the \( \alpha' \) limit, which is consistent with known result.

The integral involved in calculating the \( T_a \)'s is similar. Assuming vertex operator has the following expansion,

\[
V(y) = \sum_{n=-\infty}^{\infty} e^{i k \cdot x_n y^n} e^{\sqrt{\alpha'} k \cdot p \ln y},
\]

where \( a_n \) are expansion coefficients, the integration of interest \( \int_0^1 \frac{dy}{y} V(y) \) can be readily carried out term-wise.

\[
\int_0^1 \frac{dy}{y} V(y) = \sum_{n=-\infty}^{\infty} e^{i k \cdot x_n} \frac{1}{\sqrt{\alpha'} k \cdot a_0 + n}.
\]

The expansion coefficients \( a_n \) are not so difficult to compute either. Keeping only the first few power terms in \( \sqrt{\alpha'} \), we have

\[
a_0 = \cdots + \epsilon \cdot \alpha_1 \left( \sqrt{\alpha'} k \cdot \alpha_{-1} - \sqrt{\alpha'} \sum_{n=1}^{\infty} \left( \frac{k \cdot \alpha_{-(n+1)}}{n+1} \right) \left( \frac{k \cdot \alpha_n}{n} \right) + O(\sqrt{\alpha'}) \right) + \epsilon \cdot \alpha_0 \left( 1 - \sqrt{\alpha'} \sum_{n=1}^{\infty} \left( \frac{k \cdot \alpha_{-n}}{n} \right) \left( \frac{k \cdot \alpha_n}{n} \right) + O(\sqrt{\alpha'}) \right) + \epsilon \cdot \alpha_{-1} \left( -\sqrt{\alpha'} k \cdot \alpha_1 - \sqrt{\alpha'} \sum_{n=1}^{\infty} \left( \frac{k \cdot \alpha_{-n}}{n} \right) \left( \frac{k \cdot \alpha_{n+1}}{n+1} \right) + O(\sqrt{\alpha'}) \right) + \cdots,
\]

and similarly for the rest of the \( a_n \).
Figure 4. The contours present in the $\alpha'$-weighted commutator calculation

5 Structure constants of the vertex operator algebra

In light of the vertex operator expression of the BCJ numerators, a natural question to ask is whether the algebraic structure observed can be identified with any existing algebra. Note especially in [42] this was done in a similar setting to explain the $E_8 \times E_8$ symmetry of the heterotic string theory, in which case all momentum inner product $k_i \cdot k_j$ appear in the exponent take integer values due to the compactification so that the world-sheet integrals can be elegantly performed. In the presence of branch cuts the story gets considerably messier. We saw in the last section that the generators can be calculated in a term-by-term basis, in this sense it is part of the universal enveloping algebra $U(g)$ of Virasoro modes, which is however too general to provide any useful information. On the other hand it is known that the self-dual sector of Yang-Mills numerator is explained by area-preserving diffeomorphism algebra as exploited in [37]. We shall see in the following discussion that in the field theory limit, the vector $\times$ vector $\rightarrow$ vector sector is indeed isomorphic to diffeomorphism. We will see that the $\alpha'$-weighted commutator (4.7) produces the familiar structure constant

$$f_{ab}^c = \delta_{a}^c k_{1b} - \delta_{b}^c k_{2a},$$  \hspace{1cm} (5.1)

up to $\alpha'$ corrections.

5.1 Reproducing the diffeomorphism algebra

For simplicity we write the vertex operator for vector particle as $V(y) = e^{i k \cdot X + \epsilon \cdot \dot{X}}$, bearing in mind that all calculations in the following are kept only to the first order in $\epsilon$'s. It is then straightforward to compute the product of two vertex operators using standard Wick contractions. Recall that the integration contours associated with the products $V_2(y_2)V_1(y_1)$ and $V_1(y_1)V_2(y_2)$ correspond to Fig 3(a) and (b) respectively. Taking a relative minus sign and phase into account, we see that the $\alpha'$-weighted commutator is given by the following formula, integrated over the contour $\gamma^+ - \gamma^-$ shown in Fig 4(a), or equivalently, over the arc
surrounding $y_1$ plus the difference $\tilde{\gamma}_2^+ - \tilde{\gamma}_2^-$ along two sides of the branch cut $(0, y_1)$ (Fig 4(b)).

$$\int_0^1 \frac{dy_2}{y_2} [V_1(y_1), V_2(y_2)]_{\alpha'} = \int_{\text{around } y_1} + \int_{\tilde{\gamma}_2^+ - \tilde{\gamma}_2^-} \frac{dy_2}{y_2} e^{\alpha' k_1 \cdot k_2 \ln(y_1-y_2)}$$

$$\left( 1 - \alpha' \epsilon_2 \cdot k_1 \frac{y_2}{y_1-y_2} + \alpha' \epsilon_1 \cdot k_2 \frac{y_1}{y_1-y_2} + \alpha' \epsilon_1 \cdot \epsilon_2 \frac{y_1y_2}{(y_1-y_2)^2} \right) : V_1(y_1)V_2(y_2) :_{\text{linear in } \epsilon}.$$  (5.2)

The $\epsilon_1 \cdot \epsilon_2$ term can be made to vanish with suitable gauge choice or for a self-dual Yang-Mills amplitude, therefore we know that it is not relevant to the structure of interest here; while the $(\epsilon_1 \cdot k_2)(\epsilon_2 \cdot k_1)$ term carries an $\alpha'^2$ and becomes sub-leading in the field theory limit. We have checked that the construction generalises to the superstring in similar fashion as the supersymmetric Berends-Giele current of [56, App. A]. For the moment let us focus first on the $\epsilon_1 \cdot k_2$ and $\epsilon_2 \cdot k_1$ terms. We will soon see that these two terms reproduce the familiar diffeomorphism structure constant multiplied by a vector (spin 1) vertex operator, whereas the factor 1 contributes a scalar (spin 0) and the $\epsilon_1 \cdot \epsilon_2$ the tensor part needed to reproduce the quartic vertex contribution in the field theory limit.

For generic values of $k_1 \cdot k_2$ the integral around $y_1$ vanishes as the radius of the arc $\varepsilon$ approaches zero. This is because the normal ordered product : $V_1(y_1)V_2(y_2) :$ contains no pole at $y_1$ so that when expanded as power series of $(y_2 - y_1)$, the integral becomes\(^5\)

$$\int_{-\pi}^{\pi} e^{i\theta} d\theta \left( c_0 + c_1 \varepsilon e^{i\theta} + \ldots \right) \xrightarrow{\varepsilon \to 0} 0.$$  (5.3)

Similarly, we consider formally expanding : $V_1(y_1)V_2(y_2) :$ in the $\tilde{\gamma}_2^+$ and $\tilde{\gamma}_2^-$ part of the integral, and note that an $n$-th power term contributes as

$$\int_{\tilde{\gamma}_2^-} dy_2(y_2 - y_1)^n e^{\alpha' k_1 \cdot k_2 \ln(y_1-y_2)} = e^{i\pi\alpha' k_1 \cdot k_2} \int_{0 \leq i \varepsilon} dy_2(y_2 - y_1)^{n+\alpha' k_1 \cdot k_2}$$

$$= \frac{1}{n + \alpha' k_1 \cdot k_2} \left[ 0 - e^{i\pi\alpha' k_1 \cdot k_2} e^{\alpha' k_1 \cdot k_2 \ln y_1} \right].$$

For generic integer $n$ the difference $\tilde{\gamma}_2^+ - \tilde{\gamma}_2^-$ then yields $\frac{2i \sin(\pi\alpha' k_1 \cdot k_2)}{n + \alpha' k_1 \cdot k_2 + 1} e^{\alpha' k_1 \cdot k_2 \ln y_1}$, which also vanishes as $\alpha' \to 0$. The only exception occurs when $n = -1$, in which case the difference $\tilde{\gamma}_2^+ - \tilde{\gamma}_2^-$ returns a finite result,

$$\frac{2i \sin(\pi\alpha' k_1 \cdot k_2)}{\alpha' k_1 \cdot k_2} e^{\alpha' k_1 \cdot k_2 \ln y_1} = 2\pi i + O(\alpha').$$  (5.4)

In other words the effect of the branch cut integration and the $\alpha'$ limit combine is equivalent to stripping off an exponential phase factor $e^{\alpha' k_1 \cdot k_2 \ln(y_1-y_2)}$ and picking up the $-1$ power term coefficient if we imagine the rest of the integrand $\left( -\alpha' \epsilon_2 \cdot k_1 \frac{y_2}{y_1-y_2} + \alpha' \epsilon_1 \cdot k_2 \frac{y_1}{y_1-y_2} \right) : V_1(y_1)V_2(y_2) :$ being expressed as a holomorphic

\(^5\)Note that the branch cut of $\ln y_2$ lies only along $y_2 < 0$, so that it can be safely expanded as well into a power series in $(y_2 - y_1)$ without producing any pole at $y_1$. In $y_2 = \ln(y_1 + (y_2 - y_1)) = \ln y_1 + \frac{1}{y_1}(y_2 - y_1) + \ldots$. 

- 15 -
whereas the $\epsilon$ and integrate further to compute higher point numerators. For these reasons in the discussion that follows we wish to incorporate more commutators and integrating the $y$ series in $(y_2 - y_1)$. The procedure just described can be recast in the language of a Cauchy integral if we would like, writing the commutator as

$$
\int_0^1 \frac{dy_2}{y_2} [V_1(y_1), V_2(y_2)]_{\alpha'} = \int_{y_1} dy_2 \alpha' (-\alpha' \epsilon_2 \cdot k_1 \frac{y_2}{y_1 - y_2} + \alpha' \epsilon_1 \cdot k_2 \frac{y_1}{y_1 - y_2}) : V_1(y_1)V_2(y_2) : |_{\text{linear in } \epsilon}
+ \text{scalars and tensors},
$$

(5.5)

up to $\alpha'$ corrections, and the result is the same as replacing all $y_2$ dependence in the numerator by $y_1$ (taking reference to Cauchy residue theorem). Plugging in the explicit form of vector (spin 1) vertex operator this gives

$$
(\alpha' \epsilon_2 \cdot k_1 \frac{y_2}{y_1 - y_2} + \alpha' \epsilon_1 \cdot k_2 \frac{y_1}{y_1 - y_2}) : \epsilon_1 \cdot \dot{X}(y_1)e^{ik_1 \cdot X(y_1)} \epsilon_2 \cdot \dot{X}(y_2)e^{ik_2 \cdot X(y_2)} ;
$$

(5.6)

and we see that the piece proportional to a vector (spin 1) vertex operator is indeed isomorphic to the diffeomorphism algebra as expected

$$
\int_0^1 \frac{dy_2}{y_2} [\epsilon_1 \cdot \dot{X}(y_1)e^{ik_1 \cdot X(y_1)}, \epsilon_2 \cdot \dot{X}(y_2)e^{ik_2 \cdot X(y_2)}]_{\alpha'} = -\epsilon_2^a \epsilon_1^b \epsilon_3^c f_{abc} \dot{X}_c(y_1) e^{i(k_1 + k_2) \cdot X(y_1)} + \text{scalars and tensors},
$$

(5.7)

where the structure constant $f_{abc}$ is given by (5.1).

### 5.2 Tensors and scalars contributions

We then proceed with rest scalar piece, 1, and tensor parts, $\epsilon_1 \cdot \epsilon_2$ and $(\epsilon_1 \cdot k_2)(\epsilon_2 \cdot k_1)$, in (5.2). As was explained earlier, the equation should be understood to represent only terms linear in all $\epsilon$'s, therefore when written explicitly the factor 1 term gives rise to a tensor operator

$$
\int_{\gamma_2^+ - \gamma_2^-} \frac{dy_2}{y_2} e^{\alpha' k_1 \cdot k_2 \ln(y_1 - y_2)} (\epsilon_1 \cdot \dot{X}(y_1) e^{ik_1 \cdot X(y_1)} \epsilon_2 \cdot \dot{X}(y_2) e^{ik_2 \cdot X(y_2)}),
$$

(5.8)

whereas the $\epsilon_1 \cdot \epsilon_2$ term corresponds to a scalar

$$
\int_{\gamma_2^+ - \gamma_2^-} \frac{dy_2}{y_2} e^{\alpha' k_1 \cdot k_2 \ln(y_1 - y_2)} \epsilon_2^a \epsilon_1^b \epsilon_3^c f_{abc} \dot{X}_c(y_1) e^{i(k_1 + k_2) \cdot X(y_1)}.
$$

(5.9)

As it happens, carrying out the integrals above can be a rather tricky task. Taylor expanding (5.8) and (5.9) and integrating the $y_2$ dependence term-wise leads to an infinite sum of vertex operators associated with all possible levels. On the other hand it is not clear whether such Taylor expansion would converge in the first place, which can become an important issue for example if we wish to incorporate more commutators and integrate further to compute higher point numerators. For these reasons in the discussion that follows
we shall leave these two operator as they were and perform the calculations directly on formulas (5.8) and (5.9) if needed.

As a double check, let us calculate the four-point s-channel numerator \( n(1234) \). In terms of commutators of vertex operators, this is given by

\[
\begin{align*}
n(1234) &= \lim_{\alpha', y_1, k_1^2 \to 0} \int_{\frac{1}{3} - \frac{1}{3}}^\frac{1}{2} \frac{dy_3}{y_3} \int_{\frac{1}{2} - \frac{1}{2}}^\frac{1}{2} \frac{dy_2}{y_2} \frac{1}{y_1} \left( f \left[ V_3(y_3), [V_2(y_2), V_1(y_1)]_{\alpha'} \right] _{\alpha'} \right) \bigg| _0, \tag{5.10}
\end{align*}
\]

where the final state is another level one vector (spin 1) particle, \( f = \epsilon_4 \cdot \alpha_1 e^{ik_1 \cdot x} \bigg| _0 \). In this case we need not only the diffeomorphism part of the algebra, but also the tensor and scalar described in (5.8) and (5.9). To evaluate the s-channel numerator, in principle we should include commutators of \( V_3 \) with these two operators before sandwich them with a vacuum and final state.

It might help better organise the derivation if we know what to expect. Recall that in [39, 40] the s-channel numerator was shown to be

\[
n(1234) = \epsilon_1^a \epsilon_2^b \epsilon_3^c \epsilon_4^d f_{ab} \sigma_{c, d} + \frac{1}{2} s_{12} \left[ (\epsilon_1 \cdot \epsilon_2) (\epsilon_2 \cdot \epsilon_4) - (\epsilon_1 \cdot \epsilon_4) (\epsilon_2 \cdot \epsilon_3) \right]
+ \frac{1}{2} \left( s_{23} - s_{13} \right)(\epsilon_1 \cdot \epsilon_2)(\epsilon_3 \cdot \epsilon_4). \tag{5.11}
\]

We will see that the second term in (5.11) can be produced by commutator of \( V_3 \) and the tensor operator (5.8), but has its value shifted; and similarly for the third term in the equation, which corresponds to that of a scalar (5.9). This difference between the two numerator prescriptions (5.10) and (5.11) can be explained by the analytic continuations introduced. We will see that the monodromy derived numerator (5.10) reproduces the correct scattering amplitude in the on-shell limit.

### 5.3 Structure constants and disc integrals

Consider first the operator product of \( V_3 \) with the tensor (5.8). In order to produce an \( \epsilon \cdot \epsilon \) term, operator \( \epsilon_3 \cdot \hat{X} \) has to Wick contract with either \( \epsilon_2 \cdot \hat{X} \) or \( \epsilon_1 \cdot \hat{X} \). Both options actually lead to similar integrations. As a demonstration of the derivation involved, let us focus on the \( \epsilon_2 \cdot \hat{X} \) contraction.

\[
\int_{\frac{1}{3} - \frac{1}{3}}^\frac{1}{2} \frac{dy_3}{y_3} \int_{\frac{1}{2} - \frac{1}{2}}^\frac{1}{2} \frac{dy_2}{y_2} \frac{1}{y_1} \left( f \left[ : \epsilon_1 \cdot \hat{X}(y_1) e^{ik_1 \cdot X} \epsilon_2 \cdot \hat{X}(y_2) e^{ik_2 \cdot X} : \right] \epsilon_3 \cdot \hat{X}(y_3) e^{ik_3 \cdot X} \right) \bigg| _0. \tag{5.12}
\]

Standard Wick contraction replaces the contracted pair by the factor \( \alpha' y_3 y_2 (\epsilon_3 \cdot \epsilon_2)/(y_3 - y_2)^2 \). We then Taylor expand the remaining operators \( \exp(ik_3 \cdot X(y_3)) \) and \( \exp(ik_2 \cdot X(y_2)) \) around \( y_1 \) to extract all the \( y_2 \) and \( y_3 \) dependence, in the hope that this manipulation simplifies the integration. At lowest order we simply have a vector (spin 1) vertex operator \( \epsilon_1 \cdot \hat{X}(y_1) e^{i(k_1 + k_2 + k_3) \cdot X(y_1)} \), so that in the \( y_1 \to 0 \) asymptotic limit this operator becomes a level one state, \( \lim_{y_1 \to 0} y_1^{-1} e^{i(k_1 + k_2 + k_3) \cdot X(y_1)} \bigg| _0 = e^{i(k_1 + k_2 + k_3) \cdot X(y_1)} \bigg| _0 \), which subsequently contracts with the final state, yielding a factor \( \epsilon_1 \cdot \epsilon_4 \). All higher power terms in the Taylor expansion can be argued to produce different asymptotic states, thereby giving no contribution to
the expectation value\(^6\). In other words, equation (5.12) yields

\[
\int_{\tilde{\gamma}_3}^{\tilde{\gamma}_2} dy_3 \int_{\tilde{\gamma}_2}^{\tilde{\gamma}_1} dy_2 e^{\alpha'k_2 k_3 \ln(y_2 - y_3)} e^{\alpha'k_1 k_3 \ln(y_1 - y_3)} e^{\alpha'k_1 k_2 \ln(y_1 - y_2)} \frac{e_2 \cdot e_3}{(y_2 - y_3)^2} \left( f \mid : e_1 \cdot \tilde{X} (y_1) e^{ik_1 X(y_1)} e^{ik_2 X(y_2)} e^{ik_3 X(y_3)} : \right) \]

\[
= (e_2 \cdot e_3)(e_1 \cdot e_4) \int_{\tilde{\gamma}_3}^{\tilde{\gamma}_1} dy_3 \int_{\tilde{\gamma}_2}^{\tilde{\gamma}_1} dy_2 e^{\alpha'k_2 k_3 \ln(y_2 - y_3)} e^{\alpha'k_1 k_3 \ln(y_1 - y_3)} e^{\alpha'k_1 k_2 \ln(y_1 - y_2)} \frac{1}{(y_2 - y_3)^2} \quad (5.13)
\]

Our remaining task is then to evaluate the above integral. At first sight a direct computation can be slightly difficult. However we can always resort to the derivation used to extract momentum kernel from monodromy relations [11] and apply the same reasoning to translate the double integral to something recognisable. Explicitly we write

\[
\int_{\tilde{\gamma}_3}^{\tilde{\gamma}_1} dy_3 \int_{\tilde{\gamma}_2}^{\tilde{\gamma}_1} dy_2 e^{\alpha'k_2 k_3 \ln(y_2 - y_3)} e^{\alpha'k_1 k_3 \ln(y_1 - y_3)} e^{\alpha'k_1 k_2 \ln(y_1 - y_2)} \frac{1}{(y_2 - y_3)^2} \]

\[= \sin(\pi \alpha' k_2 \cdot k_1) \sin(\pi \alpha' k_3 \cdot k_1) I(1324) + \sin(\pi \alpha' k_2 \cdot k_1) \sin(\pi \alpha' (k_3 \cdot k_1 + k_3 \cdot k_2)) I(1324), \quad (5.14)
\]

where

\[
I(1324) = \int_0^1 dy_3 \int_0^{y_3} dy_2 e^{\alpha'k_2 k_3 \ln(y_3 - y_2)} e^{\alpha'k_3 k_1 \ln(y_3 - y_1)} e^{\alpha'k_1 k_2 \ln(y_2 - y_1)} \frac{1}{(y_3 - y_2)^2} \quad (5.15)
\]

and

\[
I(1324) = \int_0^1 dy_2 \int_0^{y_2} dy_3 e^{\alpha'k_2 k_3 \ln(y_2 - y_3)} e^{\alpha'k_3 k_1 \ln(y_2 - y_1)} e^{\alpha'k_1 k_2 \ln(y_3 - y_1)} \frac{1}{(y_3 - y_2)^2}. \quad (5.16)
\]

From a simple change of integration variables we see that both \(I(1324)\) and \(I(1324)\) are actually proportional to beta functions.

\[
I(1324) = \int_0^1 dy_3 \frac{1}{y_3^3} e^{\alpha'(k_3 + k_2 + k_3 - k_1 + k_2 - k_1) \ln y_3} \int_{y_2 = 0}^{y_2 = y_3} y_3 d \left( \frac{y_2}{y_3} \right) \left( \frac{1}{1 - \left( \frac{y_2}{y_3} \right)^2} \right) e^{\alpha'k_2 k_3 \ln(1 - \left( \frac{y_2}{y_3} \right))} e^{\alpha'k_3 k_1 \ln(1 - \left( \frac{y_1}{y_3} \right))} e^{\alpha'k_1 k_2 \ln(1 - \left( \frac{y_1}{y_3} \right))} . \quad (5.17)
\]

Suppose if we introduce a new variable \(y'_2 = (y_2/y_3)\) and let \(y_1 \to 0\), this becomes

\[
\int_0^1 dy_3 y_3 \frac{1}{y_3^3} e^{\alpha'(k_3 + k_2 + k_3 - k_1 + k_2 - k_1) - 1} \int_0^1 dy'_2 (1 - y'_2) e^{\alpha'k_2 k_3 - 2y'_2} e^{\alpha'k_2 k_1} \]

\[
= \frac{1}{\alpha'k_2} B(\alpha' k_3 \cdot k_2 - 1, \alpha' k_2 \cdot k_1 + 1) \quad (5.18)
\]

where we used momentum conservation \(k_3 \cdot k_2 + k_3 \cdot k_1 + k_2 \cdot k_1 = k_4^2\) and the integral definition of beta function. This expression is an explicit realisation of the \(\alpha'\)-dependent Berends-Giele currents \(\phi_{AB}^{[57]}\).

---

\(^6\)Alternatively, higher power terms can be argued to contain higher powers of \(\alpha'\) as well, therefore not contributing. This is because the \(X(y)\) operator carries an overall \(\sqrt{\alpha'}\) factor.
In the $\alpha' \to 0$ limit the beta function yields
\[
\lim_{\alpha' \to 0} B(\alpha' k_3 \cdot k_2 - 1, \alpha' k_2 \cdot k_1 + 1) = \lim_{\alpha' \to 0} \frac{\Gamma(\alpha' k_3 \cdot k_2 - 1) \Gamma(\alpha' k_2 \cdot k_1 + 1)}{\Gamma(\alpha' k_3 \cdot k_2 + \alpha' k_2 \cdot k_1)} = (-1)^{k_3 \cdot k_2 + k_2 \cdot k_1} \frac{k_3 \cdot k_2}{k_3 \cdot k_2}.
\]
(5.19)

Repeating similar derivation on $I(1324)$ and plugging everything back shows that equation (5.14) gives
\[
\begin{align*}
(\epsilon_3 \cdot \epsilon_2)(\epsilon_1 \cdot \epsilon_4) \frac{s_{21}}{k_4^2} \left[ s_{31}(-1)s_{13} + s_{23} \right] + (s_{31} + s_{32})(-1)\frac{s_{23} + s_{12}}{s_{23}}
\end{align*}
\]
(5.20)

Generically an over all rescaling produces a $1/k_n^2$ as in the four-point example. The remaining integral can be identified with the $Z$-function in [57] when appropriately integrated by parts.

### 5.4 Jacobi identities and the four-point numerators

In the previous section we demonstrated that the $s$-channel numerator $n(1234)$ can be calculated from the expectation value of successive $\alpha'$-weighted commutators of vertex operators $[[V_1, V_2]_{\alpha'}, V_3]_{\alpha'}$. It is straightforward to see that the $u$-channel $n(1324)$ can be obtained by the same reasoning, and the result is that of the $s$-channel with legs 2 and 3 swapped. Note however, that the $t$-channel numerator on the other hand is not related to the other two by a simple relabelling. This is because the asymptotic state condition requires that the world-sheet coordinate $y_1 \to 0$ rather than being integrated, so that in our settings leg 1 and the rest of the legs were not placed on equal footing. Instead, the $t$-channel numerator \( \la 4 \left[ [[V_1, V_2]_{\alpha'}, V_3]_{\alpha'} \right] 0 \ra \) requires evaluating the following integrals.

\[
\begin{align*}
\int \prod_{i=1}^{3} \frac{dy_i}{y_i} V_1(y_1)V_2(y_2)V_3(y_3) - e^{-i\pi \alpha' k_1 \cdot k_2} \int \prod_{i=1}^{3} \frac{dy_i}{y_i} V_2(y_2)V_1(y_1)V_3(y_3)

- e^{-i\pi \alpha' k_3 \cdot (k_1 + k_2)} \int \prod_{i=1}^{3} \frac{dy_i}{y_i} V_3(y_3)V_1(y_1)V_2(y_2) + e^{-i\pi \alpha' (k_1 \cdot k_2 + k_2 \cdot k_3 + k_3 \cdot k_1)} \int \prod_{i=1}^{3} \frac{dy_i}{y_i} V_3(y_3)V_2(y_2)V_1(y_1),
\end{align*}
\]
(5.21)

where the integration contour of each term follows the convention described in section 4, and can be read off directly from the order of the original vertex operators. To carry out the integral above, we note that from the definition of the $\alpha'$-weighted commutator, we have

\[
[[V_1, V_2]_{\alpha'}, V_3]_{\alpha'} - [[V_1, V_3]_{\alpha'}, V_3]_{\alpha'}
\]
\[
= [V_1, [V_2, V_3]_{\alpha'}]_{\alpha'} + (e^{-i\pi \alpha' k_2 \cdot k_3} - 1) \left( V_1 V_3 V_2 + e^{-i\pi \alpha' k_2 \cdot k_2} V_2 V_1 V_3 - e^{-i\pi \alpha' k_3 \cdot k_3} V_3 V_1 V_2 - e^{-i\pi \alpha' (k_2 + k_3)} V_2 V_3 V_1 \right).
\]
(5.22)
we follow this line of thoughts and exploit the $\alpha$-

After obtaining new classes of string theory tree-level amplitudes. It is reasonable to expect that some Feynman diagram-like description of the open string amplitude exists if we follow this line of thoughts and exploit the $\alpha'$-weighted commutators or its generalisations. We then showed that the string of structure constants is given by hypergeometric functions from disc integrals. This result mirrors the colour structure of open string and semi-Abelian $Z$-theory [43, 45] obtained by employing monodromy relations in the colour decomposition formulas. As a comparison to previous discussions on algebraic interpretation of the Yang-Mills numerator, we reproduced the algebra of diffeomorphism as the vector $\times$ vector $\to$ vector part of the vertex operator algebra. We showed at four points the numerator is restored when the full algebra is taken into account. We showed in general, that the string of structure constants is given by hypergeometric functions from disc integrals.

Our newly obtained string analogue numerator, when plugged into the KLT monodromy relation produces a string version of the BCJ dual Del Duca-Dixon-Maltoni formula. Comparing the results with [43, 45] it is apparent that one can write down string generalisation of many double-copied field theory amplitudes by replacing all the commutators by the $\alpha'$-weighted and the field theory amplitudes with the corresponding open string ones. Therefore obtaining new classes of string theory tree-level amplitudes. It is reasonable to expect that some Feynman diagram-like description of the open string amplitude exists if we follow this line of thoughts and exploit the $\alpha'$-weighted commutators or its generalisations. It would be
interesting to see if the double copy expression also came from a string origin, which might shed light on loop level structures.

From the vertex operator viewpoint it is not clear to us why the kinematic numerator derived in this paper corresponds to field theory amplitudes (namely Yang-Mills) given by Feynman rules that are limited to three and four point interactions only. It is also not entirely clear whether the cubic graph organisation leads to the same decomposing of the Yang-Mills quartic vertex as the recent prescription developed in the context of CHY formulation [58–60]. We leave these interesting questions to future work.

Acknowledgements

We would like to thank N.E.J. Bjerrum-Bohr, Donal O’Connell, Yi-Jian Du, Bo Feng, Song He, Kirill Krasnov and Oliver Schlotterer, for valuable discussions and comments on the manuscript. CF is particularly grateful for Kirill Krasnov for suggesting this project. The research of CF is supported by the Fundamental Research Funds for the Central Universities (GK201803018). P. Vanhove has received funding the ANR grant “Amplitudes” ANR-17-CE31-0001-01, and is partially supported by Laboratory of Mirror Symmetry NRU HSE, RF Government grant, ag. № 14.641.31.0001. Yihong Wang is supported by MoST grant 106-2811-M-002-196. Both CF and YW are thankful for the Institute of Theoretical Physics, CAS in Beijing for hospitality during this work.
