Case report

Subacute thyroiditis associated with COVID-19

Shaikh Abdul Matin Mattar 1, 2, Samuel Ji Quan Koh, 1 Suresh Rama Chandran, 2 Benjamin Pei Zhi Cherng 3

SUMMARY
We report a case of a hospitalised patient with COVID-19 who developed subacute thyroiditis in association with SARS-CoV-2 infection. The patient presented with tachycardia, anterior neck pain and thyroid function tests revealing hyperthyroidism together with consistent ultrasonographic evidence suggesting subacute thyroiditis. Treatment with corticosteroids resulted in rapid clinical resolution. This case illustrates that subacute thyroiditis associated with viruses such as SARS-CoV-2 should be recognised as a complication of COVID-19 and considered as a differential diagnosis when infected patients present with tachycardia without evidence of progression of COVID-19 illness.

BACKGROUND
As of 1 May 2020, 17101 people with COVID-19 have been diagnosed in Singapore with migrant workers residing in dormitories forming the majority (n=14,776, 86.4%). We report a unique case of a migrant worker from Myanmar who developed subacute thyroiditis in association with COVID-19, which is the first case reported in Asia to our knowledge. On day 10 of illness, he developed anterior neck pain and sinus tachycardia with thyroid function tests revealing primary hyperthyroidism. Ultrasonography of his thyroid gland was consistent with subacute thyroiditis and he was administered oral corticosteroids, resulting in rapid clinical improvement. This case highlights the importance of good history taking and awareness of the diagnosis of thyroiditis in order to elicit the finding of anterior neck pain that can be conflated with upper respiratory tract symptoms in a persistently tachycardic patient with COVID-19.

CASE PRESENTATION
History and clinical findings
A 34-year-old man from Myanmar with no medical history or known COVID-19 exposure presented to the emergency department at Singapore General Hospital with a 4-day history of fever, dry cough, headache and anosmia. On admission, he had a temperature of 37.7°C, blood pressure of 120/90 mm Hg, heart rate of 89 beats/min, respiratory rate of 19 breaths/min and an oxygen saturation (SpO2) of 96% on room air. His oropharynx was not injected nor had any exudates. Auscultation of the lungs revealed no adventitious sounds. On examination of his neck, a diffuse asymmetric goitre was found with regions on both lobes that were hard and tender to palpation. There was no retrosternal extension or palpable bruit. Few cervical lymph nodes were palpable bilaterally. He did not have any eye signs of thyroiditis or thyroid eye disease, pretibial myxoedema or hand tremors. Additionally, examination of his skin revealed no exanthem.

Further relevant history to his thyroid status revealed no palpitations, diarrhoea, increased appetite, unintentional weight loss or heat intolerance on presentation or preceding this admission. He did not have history of thyroid disease in the past but had a positive family history for thyroid disease.

Clinical course and management
On the third day of admission, the patient complained of ongoing dry cough associated with sore throat. Vital signs remained stable and he remained afebrile. Symptomatic treatment with paracetamol and dequalinium lozenges were given. However, from the fifth day of the hospital stay (day 9 of illness), he had new complaints of an anterior neck pain with a score 5/10 that was refractory to symptomatic treatment and a new onset of tachycardia ranging from 90 to 120 beats/min. He remained afebrile with SpO2 > 96% on room air. His oropharynx was not injected nor had any exudates. Auscultation of the lungs revealed no adventitious sounds. On examination of his neck, a diffuse asymmetric goitre was found with regions on both lobes that were hard and tender to palpation. There was no retrosternal extension or palpable bruit. Few cervical lymph nodes were palpable bilaterally. He did not have any eye signs of thyrotoxicosis or thyroid eye disease, pretibial myxoedema or hand tremors. Additionally, examination of his skin revealed no exanthem.

INVESTIGATIONS
In view of tachycardia and a tender goitre found, a thyroid function test was done revealing primary hyperthyroidism with elevated free thyroxine 3 (13.4 pmol/L), free thyroxine 4 (41.8 pmol/L) and suppressed thyroid-stimulating hormone (TSH) (<0.01 mU/L). Thyrotropin receptor antibody using Roche Cobas SARS-CoV-2 test. The test for SARS-CoV-2 was positive. Initial laboratory tests on admission to the hospital showed a normal white cell count (9.8×109/L), haemoglobin level (14.3 g/dL) and platelet count (444,000/mm3). C reactive protein (CRP) level was mildly elevated at 11.3 mg/L, and lactate dehydrogenase (LDH) was within normal limits at 433 units/L. A chest X-ray (CXR) performed reported no pulmonary consolidation or pleural effusion. He was admitted to an isolation cohort ward for further management of COVID-19 upper respiratory tract infection (URTI) with consideration to transfer to a community isolation facility should he continue to remain stable without any progression of COVID-19.

C reactive protein (CRP) level was mildly elevated at 11.3 mg/L, and lactate dehydrogenase (LDH) was within normal limits at 433 units/L. A chest X-ray (CXR) performed reported no pulmonary consolidation or pleural effusion. He was admitted to an isolation cohort ward for further management of COVID-19 upper respiratory tract infection (URTI) with consideration to transfer to a community isolation facility should he continue to remain stable without any progression of COVID-19.
Oropharyngeal respiratory swab PCR: negative for respiratory viruses 1–4, metapneumovirus, rhinoviruses A/B/C, human coronavirus OC43, human coronavirus 229E, human coronavirus NL63, adenovirus, human enterovirus and human bocavirus 1/2/3/4.

Blood cultures: no bacterial growth in both aerobic and anaerobic.

Urine dipstick: negative for bilirubin, nitrite, leucocyte, glucose, ketone, blood and protein. Urobilinogen: 0.2 mg/L, while haemoglobin: 14.0–18.0 g/dL, sodium: 136–146 mmol/L, potassium: 3.6–5.0 mmol/L, creatinine: 0.65–3.70 µmol/L.

HIV: negative.

Mumps, measles and rubella IgG: positive.

Ultrasound of the neck (Figure 1) showed an enlarged thyroid gland with heterogeneous echotexture. Both lobes had hypoechoic areas with ill-defined margins corresponding to the hard regions palpable. Colour flow Doppler showed reduced blood flow in both lobes. There were no definite nodules seen in the thyroid gland. A few cervical lymph nodes with normal morphology were seen.

### DIFFERENTIAL DIAGNOSIS

Subacute thyroiditis is fundamentally a clinical diagnosis, and our patient presented with clinical manifestations that were sufficient to establish this as a leading differential diagnosis, given the new-onset neck pain, thyroid tenderness and a diffuse asymmetric goitre in the context of a preceding upper respiratory tract viral illness and hyperthyroidism. The classical ultrasound finding of hypoechoic and heterogenous enlarged thyroid gland with reduced blood flow was also supportive of the diagnosis. Furthermore, TRAb and TPOAb were negative, rendering the diagnoses of Grave’s disease and autoimmune thyroiditis unlikely. Investigations also did not support an acute infectious trigger of the subacute thyroiditis in this particular case. Hence, SARS-CoV-2 was the likely viral trigger of the subacute thyroiditis in this particular case.

### TREATMENT

In view of the significant pain and discomfort and hyperthyroidism with tachycardia, he was commenced on prednisolone at a dose of 20 mg. A steroid-tapering regimen was planned for him to decrease the dosage of prednisone to the minimum required for symptomatic relief with periodic monitoring of thyroid function. Beta-blocker treatment was also initiated with atenolol at a dosage of 25 mg every morning.

### Further investigations done upon diagnosis of thyroiditis

- Urine dipstick: negative for bilirubin, nitrite, leucocyte, glucose, ketone, blood and protein. Urobilinogen: 0.2 mg/L, specific gravity: 1.01, urine: pH 6.5.
- Blood cultures: no bacterial growth in both aerobic and anaerobic.
- Oropharyngeal respiratory swab PCR: negative for respiratory syncytial viruses A and B, influenza A and B, parainfluenza viruses 1–4, metapneumovirus, rhinoviruses A/B/C, human coronavirus OC43, human coronavirus 229E, human coronavirus NL63, adenovirus, human enterovirus and human bocavirus 1/2/3/4.

### Table 1  Summary of investigation findings on admission and after the onset of tachycardia

| Investigation (units) | Normal range | On admission | Onset of tachycardia |
|-----------------------|--------------|--------------|----------------------|
| LDH (U/L)             | 222–454      | 433          | 440                  |
| CK (U/L)              | 56–336       | –            | 45                   |
| CKMB (µg/L)           | 1.0–5.0      | –            | <1                   |
| Trop (ng/L)           | <30          | <13          | <13                  |
| Ur (mmol/L)           | 2.7–6.9      | 3.7          | 3.6                  |
| Na (mmol/L)           | 136–146      | 133          | 138                  |
| K (mmol/L)            | 3.6–5.0      | 4.4          | 4.7                  |
| Cl (mmol/L)           | 100–107      | 100          | 100                  |
| HCO3 (mmol/L)         | 19.0–29.0    | 22.6         | 27.3                 |
| Cr (µmol/L)           | 54–101       | 73           | 72                   |
| Alb (g/L)             | 40–51        | –            | 38                   |
| Bill (µmol/L)         | 7–32         | –            | 19                   |
| ALP (U/L)             | 39–99        | –            | 218                  |
| ALT (U/L)             | 6–66         | –            | 77                   |
| AST (U/L)             | 12–42        | –            | 44                   |
| GGT (U/L)             | 19–94        | –            | 234                  |
| CRP (mg/L)            | 0.2–9.1      | 11.3         | 122                  |
| Procal (µg/L)         | <0.50        | –            | 0.13                 |
| Hb (G/DL)             | 14.0–18.0    | 14.3         | 13.7                 |
| WCC (×10^9/L)         | 4.0–10.0     | 9.6          | 11.56                |
| Plt (×10^9/L)         | 140–440      | 73           | 592                  |
| Free T4 (pmol/L)      | 8.8–14.4     | –            | 41.8                 |
| Free T3 (pmol/L)      | 3.2–5.3      | –            | 13.4                 |
| TSH (µL)              | 0.65–3.70    | –            | <0.01                |
| TRAb (IU/L)           | <1.76        | –            | <1.10 (negative)     |
| TPOAb (IU/ML)         | <9.0         | –            | 2.0 (negative)       |
| COVID-19              | –            | Detected     | –                    |

**Note:** Alb, albumin; ALP, alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; Bill, bilirubin; CK, creatinine kinase; CKMB, creatinine kinase myocardial band; Cr, creatinine; CRP, C-reactive protein; GGT, gamma-glutamyl transferase; Hb, haemoglobin; HCO3, bicarbonate; K, potassium; LDH, lactate dehydrogenase; Na, sodium; Plt, platelet; Procal, procalcitonin; T3, thyroxine 3; T4, thyroxine 4; TPOAb, thyroid peroxidase antibody; TRAb, thyroid-stimulating hormone; Ur, urea; WCC, white cell count.
OUTCOME AND FOLLOW-UP

Two days after starting oral steroid treatment, the anterior neck pain had substantially reduced to a pain score of 2/10 from 5/10. The palpable hard swellings on either lobe of the thyroid gland that were found at diagnosis had rapidly disappeared after treatment, which supports the diagnosis of subacute thyroiditis.

On day 5 of treatment, the CRP level was noted to be down-trending markedly from 122 mg/L, which was documented on the diagnosis of thyroiditis to a much lower level of 16.5 mg/L. There was clinical commensuration with the down-trending inflammatory markers as the tachycardia had resolved with the neck pain.

He subsequently continued to remain well with supportive management for URTI symptoms and was discharged for follow-up with an endocrinologist after recovery from COVID-19.

He was reviewed after 10 weeks in the outpatient clinic. He had completed his tapering course of steroids and was clinically well with no symptoms. His thyroid function tests normalised with an FT4 level of 11.0 pmol/L and a TSH level of 2.10 mU/L. The thyroid gland was normal to palpation with no palpable cervical lymph nodes. His steroid therapy was stopped in view of complete resolution of his symptoms with a scheduled early follow-up.

DISCUSSION

We report the first case of subacute thyroiditis in an Asian population where the temporal sequence and the exclusion of other viral infections suggest COVID-19 as the causal factor. The importance of detailed history taking and physical examination of the neck is illustrated by our case. Capturing the distinctive history of neck pain which can often be conflated with symptoms of pharyngitis, a very common complaint in COVID-19 URTI, was key to the spearhead of the clinical reasoning process that led to the diagnosis.

Subacute thyroiditis is presumed to be caused by a viral infection or a postviral inflammatory process with clusters of disease reported during outbreaks of viral infections drawing much parallel to that of the current COVID-19 pandemic situation. This further highlights the importance for physicians to be vigilant of the diagnosis while treating patients with COVID-19 who may have multiple upper respiratory symptoms. Reviews of literature have shown that evidence for viral infection in subacute thyroiditis was linked to mumps virus, coxsackievirus, adenovirus, Epstein-Barr virus, rubella and cytomegalovirus, though a specific viral cause is not always found.\(^3\) In our case of a mild COVID-19 URTI, there was sufficient clinical and virological evidence within reasonable limits that failed to yield any other alternative viral trigger other than SARS-CoV-2.

From a pathophysiological standpoint, previous studies examining the pathology of the thyroid in Severe Acute Respiratory Syndrome proposed several mechanisms of thyroid organ damage that include host immune overreaction, immune deficiency related to infection, destruction of lymphocytes, inhibition of the innate immune response and direct cellular destruction with apoptosis playing a key role.\(^3\) Much as been discussed about ACE2, which is key to the mechanism of SARS-CoV-2 infection with the virus using it as a host cell receptor to invade human cells. More recent studies based on SARS-CoV-2 in 2020 have shown that ACE2 expression levels were highest in thyroid among other organs, such as the small intestine, kidneys, heart and adipose tissue, which does give insight into a plausible mechanism for pathophysiology of thyroiditis in COVID-19.\(^4,5\) We acknowledge similar cases reported in an 18-year-old woman in Italy and also in a middle-aged Caucasian woman in Turkey.\(^6,7\)

Given prior described literature by Ohsako et al on genetic aspects of subacute thyroiditis and certain human leuco-cyte antigens that predispose to subacute thyroiditis in a Japanese study,\(^8\) our case further sheds light onto possible research directions into gender, ethnic and therefore genetic predilection of viral subacute thyroiditis in the different populations demonstrated in reports so far.

In a hospitalised patient for mild to moderate COVID-19, a presentation of sinus tachycardia may lead to a differential diagnosis of worsening sepsis or progression of COVID-19 illness, which we agree should be dutifully ruled out as illustrated in our case report. Our case highlights the importance of being cognisant of the wide differentials in a patient with COVID-19 who develops tachycardia, such as cardiac, pulmonary, haematological and also thyroid dysfunctions, which eventually surfaced in our case. In an outbreak setting, we also note to consider physical deconditioning and anxiety as other causes of persistent unexplained tachycardia in the daytime, which has been described in prior cohort studies of SARS patients in 2004.\(^9\)

In summary, thyroiditis and resultant thyrotoxicosis should always be considered as a differential in patients with COVID-19. Though we acknowledge the wide array of differentials of tachycardia in a hospitalised patient with COVID-19, the eventual recognition of clinical, biochemical and radiological findings led to the diagnosis of a viral thyroiditis that was amenable to inexpensive treatment and rewarding outcomes of rapid symptom relief. Furthermore, the importance of clinically recognising thyroiditis transcends all levels of medical care from tertiary care providers in hospitals to primary care physicians holding the fort in the community for well and stable cases for which thyroiditis may present as a delayed complication of COVID-19.

Learning points

- COVID-19 is a novel disease for which its clinical presentation, potential complications and organ involvement are still being elucidated in literature.
- Anterior neck pain, which can be conflated with upper respiratory tract symptoms especially in the setting of COVID-19, should not be dismissed and warrants further examination and investigation as required.
- Subacute thyroiditis is a rare complication of COVID-19 that should be considered especially in the setting of persistent tachycardia without any suggestion of progression of COVID-19 and other common cardiorespiratory causes.

Acknowledgements We thank Dr Juliana Kan and Dr Tan Yuyang from the Department of Internal Medicine in Singapore General Hospital for their assistance in acquiring the ultrasound images of the thyroid gland.

Contributors SAMM, SJKQ, SRC and BPZC all contributed to the planning, conduct and reporting of the work described in the article. SAMM was the primary physician managing the patient with SJKQ. SRC was the endocrinologist consulted and assisted in acquiring the ultrasound images. BPZC was the infectious diseases consultant with an overview of the patients with COVID-19 admitted to Singapore General Hospital.

Funding The authors have not declared a specific grant for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests None declared.

Patient consent for publication Obtained.
