Abstract

Introduction: Data from the Option B+ prevention of mother-to-child transmission (PMTCT) program in Malawi show considerable variation between health facilities in retention on antiretroviral therapy (ART). In a programmatic setting, we studied whether the “model of care,” based on the degree of integration of antenatal care (ANC), HIV testing and counselling (HTC) and ART service provision—influenced uptake of and retention on ART.

Methods: We conducted a retrospective cohort study of pregnant women seeking ANC at rural primary health facilities in Zomba District, Malawi. Data were extracted from national ANC registers, ART registers and ART master cards. The “model of care” of Option B+ service delivery was determined at each health facility, based on the degree of integration of ANC, HTC and ART. Full integration (Model 1) of HTC and ART service at ANC was compared with integration of HTC only into ANC services (Model 2) with subsequent referral to an existing ART clinic for treatment initiation.

Results and discussion: A total of 10,528 women were newly registered at ANC between October 2011 and March 2012 in 23 rural health facilities (12 were Model 1 and 11 Model 2). HIV status was ascertained in 8,572 (81%) women. Among 914/8,572 (9%) HIV-positive women enrolling at ANC, 101/914 (11%) were already on ART; of those not on treatment, 456/813 (56%) were started on ART. There was significantly higher ART uptake in Model 1 compared with Model 2 sites (63% vs. 51%; p = 0.001), but significantly lower ART retention in Model 1 compared with Model 2 sites (79% vs. 87%; p = 0.02). Multivariable analysis showed that initiation of ART on the same day as HIV diagnosis, but not model of care, was independently associated with reduced retention in the first six months (adjusted odds ratio 2.27; 95% CI: 1.34–3.85; p = 0.002).

Conclusions: HIV diagnosis and treatment on the same day was associated with reduced retention on ART, independent of the level of PMTCT service integration at ANC.

Keywords: PMTCT; Option B+; Malawi; service delivery model; ANC–ART integration; retention on ART.
integrated and observed associations between the organization of service delivery and both uptake of HIV testing and retention in care on ART [6].

Our aim was to evaluate early programmatic outcomes among newly diagnosed HIV-positive women who presented to rural primary health facilities for ANC services. Specifically, we assessed the impact of integration of HIV testing and ART at ANC clinics and the initiation of ART on the same day as HIV diagnosis on uptake and retention on ART.

Methods

Services for both ANC and ART were provided at 30 health facilities in Zomba District (population 670,000 [7]; HIV seroprevalence 16.5% [8]) in Southern Malawi. Urban health facilities and referral centres were excluded from the study, in the interest of gaining a clearer understanding of the primary care experience. Twenty-three primary health facilities were included in the study (21 rural, 2 peri-urban).

Using national guidelines, treatment protocols and monitoring and evaluation (M and E) tools [7], decentralized Option B+ services were coordinated by the Zomba District Health Office with the support of Dignitas International, a Canadian medical research and humanitarian organization that has supported HIV service provision in South East Malawi since 2004 [8]. Guidelines allow ART initiation on the same day as HIV diagnosis, after a single individual counselling session, with optional deferral of the recommended group counselling session to the first follow-up visit.

We conducted a retrospective cohort study of all consecutively HIV-positive women seeking ANC at 23 rural primary health facilities in Zomba District, Malawi, between 1 October 2011 and 31 March 2012 and collected data from standardized Malawi MOH monitoring and evaluation tools. At the time of study, all health facilities kept individual patient-level data on ANC service provision in ANC registers, and individual patient-level data on ART service provision in standardized ART master cards and ART registers. Facility-level data were aggregated at all health facilities every three months and entered into an electronic database for cohort reporting by the MOH Department of HIV and AIDS M&E team. Patient-level data on ANC and ART services were not linked as part of the MOH Department of HIV and AIDS M&E team. Patient-level data included timing and uptake of and retention on ART at three and six months from initiation. As per the national guideline, women on ART were counted as “lost to follow-up” if they were expected to have run out of ART for two or more months (based on the number of tablets given at the last visit) and were not known to have transferred out, stopped or died. Comparisons between models were made using chi-square tests and nonparametric independent sample median tests.

In order to consider a cascade of Option B+ services at each facility, we extrapolated all women who were projected to be defined as follows: (HIV prevalence observed in model x the number not tested in model) + new HIV positives in model.

To explore factors associated with being lost to follow up within the first six months from starting ART, binary logistic regression models were fitted with being lost to follow up by six months as the outcome variable. Crude odds ratios (OR) and adjusted odds ratios (aORs) with 95% CI’s were calculated and were controlled for all available variables in the model, namely, mothers’ age, parity, health facility model of care, health facility monthly number of ANC registrations and timing of ART initiation. A significance level of 0.05 was set for all statistical testing. Ethics approval was obtained from the Malawi National Health Science Research Committee (#1084) and the International Union Against Tuberculosis and Lung Disease Ethics Advisory Group (#71/12). As this was a retrospective record review, no consent was required.

Results

A total of 10,528 pregnant women were registered at ANC clinics during the study period, with 3,842 registered at Model 1 (n = 12) clinics and 6,686 at Model 2 (n = 11) clinics (Table 1).

In individual patient-level data analysis of the women who were found to be HIV positive and eligible for ART, there was a significantly higher rate of ART uptake in Model 1 compared with Model 2 sites (63% vs. 51%; p = 0.001). The median number of days between HIV diagnosis and ART start was 0 (IQR 0–28) in Model 1 sites and 26 (IQR 4–88) in Model 2 sites (p = 0.001). In Model 1 sites, 57% of women started ART on the same day as HIV diagnosis versus 19% (p = 0.001) in Model 2 sites.
Among HIV-positive women who actually started ART, there was a significantly higher loss-to-follow-up rate at six months in those initiating in Model 1 compared with Model 2 sites (22% vs. 8%; \( p < 0.001 \)). There was significantly higher retention at three and six months in Model 2 sites compared with Model 1 sites (Table 2).

To model a cascade of Option B+ services at health facilities by "model of care," we then considered all women who were projected to be eligible for Option B+ ART in Figure 1, combining facility-level and individual patient-level data. Because point estimates of HIV testing and of ART initiation were higher in Model 1 than in Model 2 facilities, the modelled percentages of ART eligible women who were retained on ART at three and six months were higher in Model 1 facilities (Figure 1a and b).

Multivariable analysis (Table 3) showed that only initiation of ART on the same day as the HIV diagnosis was independently associated with reduced retention in the first six months (aOR 2.27; 95% CI: 1.34–3.85; \( p < 0.002 \)).

Discussion
In this study of mainly rural health centres in Malawi, after the introduction of Option B+, uptake of ART was higher in health facilities where ANC clinics provided integrated HTC and ART initiation services (Model 1) compared with health facilities where ANC clinics only provide HTC and ART was initiated outside the ANC clinic (Model 2). However, pregnant women in Model 1 clinics had more than twice the risk of defaulting from care at six months. Defaulting was independently associated with starting ART on the same day as the HIV diagnosis. Losses from care were small between three and six months after ART initiation across both models. The negative effect of Model 1 on defaulting may be mitigated by a higher uptake of testing and ART initiation. This was suggested by a cascade of care projection showing that of women needing to start ART for PMTCT, the percentage remaining in care after six months may be higher in Model 1 clinics. The higher HIV testing coverage in Model 1 clinics has a large impact on this projection.

Among HIV-positive women who actually started ART, there was a significantly higher loss-to-follow-up rate at six months in those initiating in Model 1 compared with Model 2 sites (22% vs. 8%; \( p < 0.001 \)). There was significantly higher retention at three and six months in Model 2 sites compared with Model 1 sites (Table 2).

To model a cascade of Option B+ services at health facilities by "model of care," we then considered all women who were projected to be eligible for Option B+ ART in Figure 1, combining facility-level and individual patient-level data. Because point estimates of HIV testing and of ART initiation were higher in Model 1 than in Model 2 facilities, the modelled percentages of ART eligible women who were retained on ART at three and six months were higher in Model 1 facilities (Figure 1a and b).

Multivariable analysis (Table 3) showed that only initiation of ART on the same day as HIV diagnosis was independently associated with reduced retention in the first six months (aOR 2.27; 95% CI: 1.34–3.85; \( p < 0.002 \)).

Discussion
In this study of mainly rural health centres in Malawi, after the introduction of Option B+, uptake of ART was higher in health facilities where ANC clinics provided integrated HTC and ART initiation services (Model 1) compared with health facilities where ANC clinics only provide HTC and ART was initiated outside the ANC clinic (Model 2). However, pregnant women in Model 1 clinics had more than twice the risk of defaulting from care at six months. Defaulting was independently associated with starting ART on the same day as the HIV diagnosis. Losses from care were small between three and six months after ART initiation across both models. The negative effect of Model 1 on defaulting may be mitigated by a higher uptake of testing and ART initiation. This was suggested by a cascade of care projection showing that of women needing to start ART for PMTCT, the percentage remaining in care after six months may be higher in Model 1 clinics. The higher HIV testing coverage in Model 1 clinics has a large impact on this projection.

Early studies after the introduction of Option B+ in Malawi have shown a sharp increase of ART initiations amongst pregnant HIV-positive women, which has been acknowledged as a success of the national PMTCT programme [2,3]. Full integration of PMTCT services in ANC clinics may offer the best opportunity of achieving high ART uptake due to direct linkage of care [9]. However, the model of integration in high prevalence, low resource contexts may also have an impact on downstream retention. Our current analysis confirms the

| Lost to follow up at six months | 66 (15%) | 47 (22%) | 19 (8%) | 0.001 |
| Transferred out at six months | 13 (3%) | 5 (2%) | 8 (3%) | 0.58 |
| Stopped ART at six months | 7 (2%) | 3 (1%) | 4 (2%) | 0.58 |
| Died at six months | 2 (0.5%) | 0 | 2 (1%) | 0.5 |
finding from an earlier health facility-level analysis in an operational setting, where we observed that model of care had impact on retention in care [6], with worse program indicators in facilities in which women receive the first dose of ART at the ANC clinic and are then transferred to the ART clinic for ART follow-up. Importantly, with patient-level data we are now able to demonstrate that same day HIV diagnosis and ART initiation is associated with increased risk of defaulting independently from the model of care. The potential negative impact of same day HIV diagnosis and ART initiation in an operational setting has been described before in a study that did not consider model of care [3] and may have many reasons [10]. Antenatal women may experience considerable peer and/or staff pressure to initiate ART. But if they are referred from ANC to an ART clinic, this may create a non-confrontational opportunity to defer or avoid ART initiation if they have misgivings, need time to disclose to their partners or require more reflection on the implications of their HIV diagnosis [11,12]. Retention on ART may be improved through improved counselling by health care staff at ANC clinics, by avoiding initiation of ART on the same day as HIV testing and/or by peer support at health facilities and in the community. Some of these interventions are currently being studied [13,14]. Our findings are compatible with the assumption that women need time to adjust to their HIV diagnosis before initiation on ART, no matter where it is offered. The challenge of making optimal use of the direct linkage of care in an integrated ANC-PMTCT service whilst respecting the individual's need for unhurried ART initiation is considerable in circumstances where many women visit an ANC clinic only once during pregnancy and often at a late stage of gestation [15].

Figure 1. (a) Number and (b) proportion of women starting and retaining in ART care when extrapolating number of women eligible for Option B+ ART in cascade of care. *Number of women projected to be eligible for Option B+ ART = (HIV prevalence observed in model × the number not tested in model) ÷ new HIV positives in model.
that they implemented and how that choice might have factors on retention in care. A further limitation is that we did effects of health systems, health care worker and patient-level representative of health facilities outside Zomba District or of clinics, it is theoretically possible that women self-transferred to start ART at other health facilities. Results may not be representative of health facilities outside Zomba District or of larger, urban clinics, and we did not explore in great detail the effects of health systems, health care worker and patient-level factors on retention in care. A further limitation is that we did not study the reasons why health facilities chose the model that they implemented and how that choice might have affected the outcomes that were observed

Conclusions

In health facilities where ANC clinics provide integrated HTC and ART initiation services (Model 1), we observed significantly higher uptake of ART but lower retention on ART, compared with health facilities where ANC clinics only provide HTC and ART was initiated outside the ANC clinic (Model 2). Initiation of ART on the same day as HIV diagnosis was associated with reduced retention in the first six months after ART initiation, independent of model of care. Further context-specific, patient-level research is needed to evaluate how retention may be impacted on by a same-day “test and treat” strategy in high prevalence, low resource settings. Such research would have important implications beyond the prevention of vertical transmission, given the interest in adopting “test and treat” for all people living with HIV by the WHO in the near future.

*Adjusted for all variables in the models.

This operational research has utilized routine MOH data to provide insight into optimal implementation of Option B+ in a real-world setting. Some care needs to be taken with the interpretation of our findings. Although we checked names and registration numbers of pregnant women across the study clinics, it is theoretically possible that women self-transferred to start ART at other health facilities. Results may not be representative of health facilities outside Zomba District or of larger, urban clinics, and we did not explore in great detail the effects of health systems, health care worker and patient-level factors on retention in care. A further limitation is that we did not study the reasons why health facilities chose the model that they implemented and how that choice might have affected the outcomes that were observed
