Prevalence and severity of genu valgum among school children aged 6-12 years in rural South India

Sharankumar Holyachi, Mallikarjun K. Biradar*, Ravindranath A. Bhovi

ABSTRACT

Background: Fluorine is the most abundant element in nature, and about 96% of fluoride in the human body is found in bones and teeth. Fluorosis is caused by exposure to a continuous high level of fluoride for a long time leads to dental and skeletal deformities. Study was done to assess the prevalence and severity of genu valgum among the school children in rural Koppal.

Methods: The present cross-sectional study was carried out among all the students, in the age group 6-12 years in Koppal taluk from August 2016 to December 2016. Data was compiled, tabulated and analyzed using proportions and chi-square test.

Results: The total school children enrolled in study 1722, the mean age group was 9.24. 31.4 % were in the age group of 10-11, Male students constituted about 45.1%. Majority of the students had nuclear family in their house (59.8%). Almost half of the study subjects were in class III socio-economic status (42.7%). The prevalence of genu valgum was 11.2%.

Conclusions: The study finding interprets the prevalence of genu valgum is high in the community.

Keywords: School children, Genu valgum, Prevalence, Fluorosis

INTRODUCTION

Fluorosis is an important public health problem in 24 countries across the globe.1 Fluoride in water and eatables is mostly of geological origin.2 A continuous levels of fluoride more than 1.5 ppm and above in drinking water is considered hazardous for the health.1,2 In India, the disease is endemic in about 275 districts of 20 states and UT’s, and about 62 million people in India suffer from dental, skeletal and non-skeletal fluorosis. Out of these; 6 million are children below the age of 14 years.3,4 Skeletal fluorosis clinically manifests in the form of various deformities viz. Genu varum, Genu valgum and Kyphosis.3 The disease severity depends on many factors like age, nutritional status and response of the individual to exposure.6

World Health Organization (WHO) has set the upper limit of fluoride concentration in drinking water at 1.5 mg/L, and The Bureau of Indian Standards, has therefore, laid down Indian standards as 1.0 mg/L as maximum permissible limit of fluoride with further remarks as “lesser the better”.7,8 Exposure to very high fluoride over a prolonged period of time results in acute to chronic skeletal fluorosis. It was stated in 1993 that crippling skeletal fluorosis might occur in people who have ingested 10 to 20 mg of fluoride per day for over 10 to 20 years. Early stages of skeletal fluorosis start with pain in bones and joints, muscle weakness, sporadic pain, stiffness of joints and chronic fatigue. During later stages, calcification of the bones takes place, osteoporosis in long bones, and symptoms of osteosclerosis where the bones become denser and develop abnormal crystalline structure. General skeletal fluorosis directly affects the economy of villagers as it causes illness and debilitation.
not only in humans but, also in their domestic animals, on which they depend for their basic income. Skeletal fluorosis leads to impairment, disability and subsequently makes the affected subject handicap. Therefore, they are unable to get employment or labour for their daily livelihood, lead their life as dependents on others.¹

METHODS

The present cross-sectional study was conducted from August 2016 to December 2016 using the method of population proportionate to size sampling in the age group of 6 to 12 years children. Using the list of villages as per the 2011 census report of Koppal district and by cluster interval 15 villages were selected. Permission from the authorities of education department was obtained. In the selected villages, the primary school visit was done and children in the age group of 6 to 12 years were selected and examined. Total of 1722 students (776 boys and 946 girls) were interviewed and examined. They were interviewed through oral questionnaire method and desired information was collected using pre-designed and pre-tested proforma.

Genu valgum was measured with the help of a divider and a plastic scale. The degree of genu valgum is measured by the distance between the medial malleoli at the ankle when the child stands or lies down with the knees touching each other and accordingly it is graded as Mild (<5 cm), Moderate (5-10 cm) and Severe (>10 cm).⁹ Operationally those with moderate and severe degree of genu valgum were considered as having genu valgum.

RESULTS

Our study subjects constituted about 1722; the mean age group was 9.24. 31.4% were in the age group of 10-11, and 16.7% were 12 years and equal. Male students constituted about 45.1% and 54.9% were female. Majority of the students had nuclear type of family in their house (59.8%), while only 12.9% were 3 generation family. Almost half of the study subjects were in class III socio-economic status (42.7%), while only 1.4% was in class I SES (Table 1).

Table 1: Socio-demographic indicators of study participants.

| Indicators                | Frequency | Percentage (%) |
|---------------------------|-----------|----------------|
| **Age in years**          |           |                |
| 6-7                       | 492       | 28.6           |
| 8-9                       | 402       | 23.3           |
| 10-11                     | 540       | 31.4           |
| ≥12                       | 288       | 16.7           |
| **Gender**                |           |                |
| Male                      | 776       | 45.1           |
| Female                    | 946       | 54.9           |
| **Type of family**        |           |                |
| Nuclear                   | 1030      | 59.8           |
| Joint                     | 470       | 27.3           |
| 3-generation              | 222       | 12.9           |
| **Socio-economic status** |           |                |
| I                         | 24        | 1.4            |
| II                        | 238       | 13.9           |
| III                       | 736       | 42.7           |

| Total | 193(100.0) | 106 (100.0) | 1722 (100.0) |       |

χ² = 5.477, df=4, P=0.242.

The prevalence of the genu valgum was 11.2%. There is statistically significant associations was observed between various age group with occurrence of fluorosis (p<0.05) (Table 2).

There is no statistical significant associations was observed between gender with occurrence of fluorosis (p=0.536) (Table 3).

There was no statistical significant associations was observed between families with occurrence of fluorosis (p=0.715) (Table 4).

There is no statistical significant associations was observed between socio-economic status with occurrence of fluorosis (p<0.05) (Table 5).

DISCUSSION

The prevalence of genu valgum in our study was 11.2%. A study by Arjunan et al in Kaiwara village, Karnataka showed the prevalence of genu valgum to be 11.0% among the school children, and study by NIN in Nawada district of Bihar showed the prevalence of genu valgum to be 20.5% in 1 to 5 year age group in Fluorosis affected village and 14.0% in the age group of 6 to 11 years. Bharati et al studied showed a prevalence of 5.4% in neighboring Gadag district. Bharati et al study showed a prevalence of 5.4% in neighboring Gadag district. Our study findings shows almost similar results when compared with gender distribution whereas study done by NIN in Nawada district of Bihar showed no perceivable difference in genu valgum among males and females and study done by Chakma et al in Mandla district of Madhya Pradesh showed that genu valgum is more among males as compared to females.

CONCLUSION

The study relates the occurrence of skeletal fluorosis to high levels of fluoride in prime drinking water sources, mainly deep tube wells. An immediate change in water supply to common water source along with health education to the community is highly desirable. The simple interventions include provision of surface water, rainwater and consumption of Low-fluoride groundwater. Other interventions are defluoridation of water through flocculation and adsorption. Similarly, health education
and better nutrition are the some of the cost-effective intervention measures.

**ACKNOWLEDGEMENTS**

Authors would like to thank the Director KIMS, Koppal and BEO, Koppal taluk for permitting us to conduct the study. Authors express sincere gratitude to all the participants of study. Authors also acknowledge the immense help received from the head masters and teaching staff of all the schools. The authors are also grateful to authors, editors and publishers of all those articles, journals and books from where the literature for this article has been reviewed and discussed.

Funding: No funding sources
Conflict of interest: None declared
Ethical approval: The study was approved by the Institutional Ethics Committee
