1. Introduction

Increasing evidences have revealed that oxidative stress is closely related to neurodegenerative diseases, such as Parkinson’s disease and Alzheimer’s disease. In the body, excessive reactive oxygen species (ROS) is commonly considered the main cause corresponding to oxidative stress [1–3]. ROS, such as hydrogen peroxide (H$_2$O$_2$), superoxide anions, and hydroxyl radicals, can stimulate cells which cause structural damage including lipid peroxidation and DNA and protein oxidation, promote oxidative stress, and disrupt the redox balance of the body, as well as change the normal function and morphology of cells [4]. There are a variety of antioxidant systems in cells, while the synergistic antioxidant effect is mainly achieved by eliminating intracellular ROS to prevent oxidative damage to the body [5]. In fact, oxidant/antioxidant levels are critical for neurodegeneration or neuroprotection, in which enzymes such as superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GSH-Px) constitute the key antioxidant defenses [6]. Excessive ROS not only is closely related to mitochondrial dysfunction but also can increase intracellular Ca$^{2+}$ concentration and activate some intracellular apoptotic pathways. Among them, the PI3K/Akt signaling pathway is closely correlated to it, which is also involved in the changes of Bcl-2 family proteins and the activation of caspase family proteins [7].

It is no doubt that herbal medicines are beneficial for treating various diseases with low toxic and side effects. Zanthoxylum bungeanum, belonging to the Rutaceae family, is a known medicinal plant widely distributed in China. Z. bungeanum pericarp is a known spice in China and widely used in cooking because of its unique fragrance and taste...
2. Materials and Methods

2.1. Materials and Chemicals. Hydroxy-α-sanshool (HAS) (purity was higher than 98%) used in the present study was isolated from the Z. bungeanum pericarps and supplied by the PUSH Bio-Technology (Chengdu, China). Fetal bovine serum (FBS) and horse serum (HS) were purchased from the Hyclone Co. (Logan, UT, USA). H$_2$O$_2$ was purchased from the Nanjing Jiancheng Bioengineering Institute (Nanjing, China). The assay kits for LDH, CAT, and GSH-PX were purchased from ImmunoWay Biotechnology Co. (Suzhou, China). The assay kits for DCFH-DA, MDA, and SOD and horseradish peroxidase (HPR-) conjugated secondary antibody were purchased from the Beyotime Institute of Biotechnology (Haimen, China). The assay kits for LDH, CAT, and GSH-PX were purchased from the Nanjing Jiancheng Bioengineering Institute (Nanjing, China). The 5,5′,6,6′-tetrachloro-1,1′,3′,3′-tetraethyl-imidacarbocyanine iodide (JC-1) was obtained from the Jiangsu KeyGen Biotech. (Nanjing, China). All other reagents used in the experiments were of analytical grade.

2.2. Cell Culture and Treatment. The PC12 cells were purchased from Wuhan Pu-nuo-sai Life Technology Co. Ltd. (Wuhan, China) and used throughout the study. PC12 cells were cultured in RPMI-1640 medium containing 5% FBS (v/v), 5% horse serum, penicillin (100 units/mL), and streptomycin (100 μg/mL) at 37°C in a humidified atmosphere of 5% CO$_2$. Cells were subcultured twice a week, and only those in the exponential growth phase were used in experiments.

PC12 cells were pretreated with different concentrations of HAS (15, 30, and 60 μM) for 2 hours and then incubated with 90 μM H$_2$O$_2$ for another 4 hours. The control group was administered with the same amount of 1640 medium and then stimulated with H$_2$O$_2$. HAS was solubilized with DMSO and subsequently diluted in culture medium with the final concentration of DMSO less than 0.1% (v/v).

2.3. Determination of Cell Viability. Cell counting kit-8 was used to test cell activity. Before the formal experiment, the cytotoxicity of HAS on PC12 cells was first investigated. Briefly, PC12 cells were cultured in 96-well plates with 1 × 10⁴ cells per well and incubated with PC12 cells with 6.5-120 μM of HAS for 24 hours. Subsequently, CCK-8 solution was added to each well and cells were kept in a humidified atmosphere of 5% CO$_2$ at 37°C for 1 hour. Finally, the optical density (OD) values at 450 nm were measured by a microplate reader (Bio-Rad, Hercules, CA, USA). After that, PC12 cells were pretreated with different concentrations of HAS (7.5-120 μM) for 1-4 hours and then incubated with 90 μM H$_2$O$_2$ for another 4 hours to select the optimal working concentration of HAS for the further experiments.

After selecting the optimal time and concentration of HAS, the cells were incubated at 37°C for 24 hours, pretreated with HAS (final concentrations in the well were 15, 30, and 60 μM) for 2 hours, and then stimulated with H$_2$O$_2$ (final concentration was 90 μM) for 4 hours. The control group was administered with the same amount of 1640 medium, while the positive group was incubated with 100 μM vitamin C and then stimulated with H$_2$O$_2$.

2.4. Nuclear Staining with DAPI. PC12 cells were seeded in 6-well plates with a density of 1 × 10⁵ per well. The cells were incubated at 37°C for 24 hours and pretreated with HAS (final concentrations in the well were 15, 30, and 60 μM) or 100 μM vitamin C for 2 hours and then stimulated with H$_2$O$_2$ (final concentration was 90 μM) for 4 hours. Subsequently, the cells were washed twice with PBS and then fixed with 10% paraformaldehyde in each well. After fixation, the cells were stained with DAPI solution, incubated at room temperature for 5 min, and then washed three times with PBS. Finally, the staining of the cells was observed under a fluorescence microscope (Olympus, IX-83, Tokyo, Japan).

2.5. Apoptosis Assay by Flow Cytometer. For the apoptosis of PC12 cells, the Annexin V/FITC kit was used. The cells were incubated in 6-well plates with a density of 1 × 10⁵ per well and given different concentrations of HAS (final concentrations in well were 15, 30, and 60 μM) or 100 μM vitamin C and H$_2$O$_2$ as described above. Subsequently, cells were collected and washed twice with PBS at 4°C, while the supernatant was removed by centrifugation. At the final concentration, the cells were suspended with 500 μL binding buffer and incubated with 5 μL Annexin V-FITC and 5 μL PI for 15 minutes at room temperature; then a FACS Canto II Flow cytometer (BD Company, New York, NY, USA) was used to detect cell apoptosis.

2.6. Assessment of Mitochondrial Membrane Potential. The decrease of intracellular mitochondrial membrane potential (MMP, ΔΨ$_{m}$) can be used as an important indicator of mitochondrial dysfunction, JC-1 is commonly considered as an...
ideal probe to evaluate $\Delta \Psi_m$. At a hyperpolarized membrane potential, JC-1 aggregates in the mitochondrial matrix to form polymers that emit red fluorescence; while when it is at the depolarized membrane potential, JC-1 only emits green fluorescence as a monomer. Therefore, the fluorescence transformation will directly reflect the $\Delta \Psi_m$ changes. Consequently, in our present study, PC12 cells were seeded in 6-well plates and treated as described in the individual experiment, then incubated with JC-1 at 37°C in the dark for 15 min. After washing the cells twice with PBS, the cells’ fluorescence was measured by a using a laser confocal microscopy (Leica, SP8 SR, Wetzlar, Germany).

2.7. Detection of Intracellular ROS Accumulation in PC12 Cells. In an oxidized environment, DCFH-DA can be transformed into green fluorescent DCF in the cell and the intracellular ROS could be monitored by fluorescent probe DCFH-DA. Briefly, cells were incubated in 6-well plates with different pretreatment or stimulation. Subsequently, the supernatant was removed and cells were incubated with DCFH-DA (10 μM) for 20 min at 37°C in a dark environment and followed by washing for three times with PBS. Intracellular ROS was analyzed by measuring the fluorescence intensity of DCF with a FACSCanto II Flow cytometer (BD Company, New York, NY, USA).

2.8. Determination of MDA, SOD, GSH-Px, and CAT in H$_2$O$_2$-Induced PC12 Cells. The cells were incubated in 6-well plates and given different concentrations of HAS and H$_2$O$_2$ as described above. The supernatants were removed; then cells were washed with PBS for three times. Subsequently, the cells were lysed by lysis buffer, which was collected and centrifuged to obtain the total cell protein. Protein concentrations, MDA level, and activities of SOD, GSH-Px, and CAT were determined using commercial assay kits according to the manufacturer’s instructions.

2.9. Western Blotting Assay. After treating as described in the individual experiment, cells were harvested and total proteins were extracted using RIPA lysis buffer. The protein concentrations were determined using BCA protein assay reagents; subsequently, the total protein (30 μg) was separated by 12% SDS-PAGE, then transferred to the PVDF membrane. After blocking by sealing fluid (5% skimmed milk), the PVDF membrane was incubated overnight with diluted primary antibodies of C-caspase-3, Bax, Bcl-2, PI3K, p-PI3K, Akt, and p-Akt (dilution 1:1000), respectively, at 4°C. Subsequently, the PVDF membrane was incubated with HPR-conjugated secondary antibody (1:5000) at room temperature for 1 hour. Finally, the protein bands were stained with ECL detection kits, and β-actin was used as the internal reference. Image analysis software ImageJ (version 1.51, National Institutes of Health, MD, USA) was used for gray analysis.

2.10. Determination of Cell Viability after the Inhibition of Signaling Pathway. To further examine the role of the PI3K/Akt signaling pathway in HAS protecting PC12 cells from H$_2$O$_2$ stimulation, we used a chemical inhibitor LY294002 to inhibit the expression of the PI3K/Akt signaling pathway by CCK-8. In this part, the HAS group was incubated with 60 μM HAS and 90 μM H$_2$O$_2$, and the HAS +LY294002 group was pretreated with 20 μM LY294002 for 1 hour and then incubated 60 μM HAS and 90 μM H$_2$O$_2$, while the LY294002 group was only treated with LY294002 and H$_2$O$_2$.

2.11. Statistical Analysis. Data are presented as the mean ± standard deviations (SD). Statistical comparisons except the seizure rate were made by Student’s t-test or one-way analysis of variance (ANOVA) using GraphPad Prism 5 software (GraphPad Software Inc., La Jolla, CA). $P < 0.05$ was considered the significant level.

3. Results

3.1. HAS Protects the Cell Viability of H$_2$O$_2$-Stimulated PC12 Cells. As can be seen from the Figure 1(b), HAS at the concentration ranging from 7.5 to 120 μM had no obvious effects on the viability of PC12 cells and the viability of all groups was approximate. In addition, CCK-8 assay results showed that 90 μM H$_2$O$_2$ treatment could significantly decrease the viability of PC12 cells, making them 40% lower than the normal group ($P < 0.01$) (Figures 1(a) and 1(d)). What is more, it can be seen from Figure 1(c) that the optimal working time for HAS was 2 hours. Importantly and interestingly, pretreatment with HAS (15, 30, 60, and 120 μM) for 2 hours could significantly concentration-dependently increase the cell viability of H$_2$O$_2$-stimulated PC12 cells, compared to the control PC12 cells ($P < 0.01$) (Figures 1(a) and 1(d)).

3.2. HAS Suppresses Apoptosis in H$_2$O$_2$-Stimulated PC12 Cells. To evaluate the apoptosis of PC12 cells, DAPI staining and flow cytometric assay with Annexin V-FITC/PI staining were utilized. As shown in Figure 2(a), nuclear morphological changes of the H$_2$O$_2$-stimulated PC12 cells were examined by staining with cell permeable DNA dye DAPI. For normal PC12 cells, PC12 cells were alive and the cell nucleus was round and intact with faint DAPI staining. However, after stimulation with 90 μM H$_2$O$_2$ for 2 h, nuclear shrinkage or condensation and improved brightness could be obviously observed in the cell nucleus, indicating characteristic apoptotic features appeared. Interestingly, pretreatment with 100 μM vitamin C or HAS (15, 30, and 60 μM) significantly attenuated the apoptosis induced by H$_2$O$_2$ in PC12 cells, compared to the control PC12 cells. Besides that, we also found the protective effect of 60 μM HAS was approximated to 100 μM vitamin C.

Moreover, the further results of flow cytometric assay also confirmed the DAPI staining experiment. After induction with 90 μM H$_2$O$_2$, the apoptosis rate of PC12 cells sharply increased to 48.74% compared with the normal group 2.21% ($P < 0.01$). However, pretreatment with 100 μM vitamin C or different concentrations of HAS (15, 30, and 60 μM) for 2 hours significantly improved the apoptosis induced by H$_2$O$_2$ stimulation ($P < 0.01$) with an obvious concentration-dependent manner, compared to the control PC12 cells (Figure 2(b)).

Besides, we also used JC-1 probe to detect the loss of $\Delta \Psi_m$ in PC12 cells exposed to H$_2$O$_2$. $\Delta \Psi_m$ was determined according to the green/red fluorescence ratio in PC12 cells. As shown...
in Figure 3, after incubation with 90 μM H₂O₂ for 2 h, the green fluorescence of the PC12 cells increased sharply, and the ratio of green/red fluorescence became more than 80%. All of these indicated an obvious decline of ΔΨₘ. However, pretreatment with 100 μM vitamin C or HAS (15, 30, and 60 μM) reversed the green/red ratio significantly, while 60 μM H₂A Sc o u l d exploit the advantages to the full (Figure 3). All the above results suggested that HAS could significantly suppress H₂O₂-stimulated apoptosis in PC12 cells.

3.3. HAS Decreases the H₂O₂-Stimulated ROS Generation in PC12 Cells. Results of the above studies revealed that HAS could suppress H₂O₂ stimulation-induced apoptosis in PC12 cells. Importantly, cells stimulated by H₂O₂ will produce excessive ROS, which is also an important cause of cell apoptosis [5, 21]. To investigate the possible mechanisms for the antiapoptotic effects of HAS on H₂O₂-induced PC12 cells, we determined the ROS generation in PC12 cells. We used the fluorescence probe DCFH-DA to further explore whether HAS could prevent H₂O₂-stimulated ROS generation and resulting oxidative stress. As can be seen from the Figure 4, it was found that when the cells were exposed to 90 μM H₂O₂, the ROS produced in the cells increased sharply, compared to the normal cells (P < 0.01). However, pretreatment with 100μM vitamin C or HAS (15, 30, and 60 μM) significantly reduced the intracellular ROS accumulation in H₂O₂-induced PC12 cells, compared to the control cells (P < 0.01).

3.4. HAS Enhances the Activities of ROS Scavenging Enzymes in H₂O₂-Stimulated PC12 Cells. Intracellular MDA, SOD, GSH-Px, and CAT are commonly used biomarkers for the evaluation of the oxidative stress level of cells or tissues [21–23]. Thus, to clarify whether HAS protects PC12 cells from H₂O₂ induced damage through antioxidant action or not, we studied the effect of HAS on MDA production and activities of ROS scavenging enzymes (SOD, GSH-Px, and CAT) in H₂O₂-stimulated PC12 cells. As shown in Figure 5, an extremely significant increase in MDA was observed in PC12 cells exposed to 90 μM H₂O₂ for 2 hours (P < 0.01), compared to the normal cells. However, this growth trend was greatly alleviated by pretreatment with 100 μM vitamin C or HAS (15, 30, and 60 μM) for 2 hours (P < 0.01), compared to the control cells. On the other hand, the amount of antioxidant enzymes including SOD, GSH-Px, and CAT is reduced sharply in H₂O₂-stimulated PC12 cells.
At the same time, the content of the three enzymes can be increased to different degrees by incubating the cells with HAS for 2 hours \((P < 0.01)\). All the above results indicate that HAS treatment might be beneficial for protecting PC12 cells from the \(\text{H}_2\text{O}_2\)-caused damage through enhancement of activities of ROS scavenging enzymes.

**3.5. HAS Regulates the Expressions of Caspase-3, Bax, and Bcl-2 in \(\text{H}_2\text{O}_2\)-Stimulated PC12 Cells.** In order to explore the molecular mechanism for antiapoptotic effects of HAS on \(\text{H}_2\text{O}_2\)-stimulated PC12 cells, western blotting assays were carried out to detect the expressions of caspase-3, Bax, and Bcl-2 in cells. The Bcl-2 family proteins are key regulatory factors in mitochondrial-mediated apoptosis, which are compared with the normal cells. At the same time, the content of the three enzymes can be increased to different degrees by incubating the cells with HAS for 2 hours \((P < 0.01)\). All the above results indicate that HAS treatment might be beneficial for protecting PC12 cells from the \(\text{H}_2\text{O}_2\)-caused damage through enhancement of activities of ROS scavenging enzymes.

divided into two categories: proapoptotic proteins (Bax, Bim, Bak, etc.) and antiapoptotic proteins (Bcl-2, Bcl-xl, Mcl-1, etc.) [24]. As shown in Figure 6(a), compared to the normal cells, 90 μM H₂O₂ stimulation significantly downregulated the antiapoptotic protein of Bcl-2 in PC12 cells (P < 0.01), while upregulating the proapoptotic proteins of Bax and cleaved caspase-3 (P < 0.01). However, the present results also showed that HAS (15, 30, and 60 μM) and 100 μM vitamin C could reverse abovementioned changes and upregulated Bcl-2 (P < 0.01), whereas they could downregulate caspase-3 in H₂O₂-stimulated PC12 cells (P < 0.01), compared to the control cells. Besides these, Bax could be downregulated by treatment with 100 μM vitamin C or HAS at the concentrations of 30 and 60 μM in H₂O₂-stimulated PC12 cells (P < 0.01), compared to the control cells.

3.6. HAS Regulates the Expressions of PI3K, p-PI3K, Akt, and p-Akt in H₂O₂-Stimulated PC12 Cells. The PI3K/Akt signal pathway is essential for the survival of neurons related to suppression of apoptosis [25]. In our present results as shown in Figure 6(b), it was found that expressions of Akt, p-Akt, and p-PI3K in PC12 cells were significantly decreased after stimulation with H₂O₂ for 2 hours (P < 0.01), compared to the normal cells. However, pretreatment with HAS (15, 30, and 60 μM) and 100 μM vitamin C significantly upregulated the p-Akt and p-PI3K in PC12 cells (P < 0.01), compared to the control cells. Besides, pretreatment with HAS (30 and 60 μM) could also significantly upregulate Akt in H₂O₂-stimulated PC12 cells (P < 0.01), compared to the control PC12 cells, while PI3K expression difference was not statistically significant. These results suggested that HAS may possess protective potentials on H₂O₂-stimulated PC12 cells via the PI3K/Akt pathway.

To further explore whether the PI3K/Akt pathway is the key in the protective effect of HAS, we used a chemical inhibitor LY294002 to inhibit the expression of the PI3K/Akt signaling pathway. As shown in Figure 7, after incubation with 90 μM H₂O₂, the viability of PC12 cells dropped to nearly 40%; the LY294002 group was approximated to it. Besides that, the HAS group could increase the viability of PC12 cells to 60%, while the HAS/LY294002 group just increased a little. All of these data showed that HAS possessed protective potentials on H₂O₂-stimulated PC12 cells via the PI3K/Akt pathway.

Figure 5: Effects of HAS on SOD, GSH-Px, MDA, and CAT in H₂O₂-stimulated PC12 cells. The levels of MDA and activities of SOD, CAT, and GSH-Px were determined by commercial assay kits. PC12 cells were treated with vitamin C (100 μM) or HAS (15, 30, and 60 μM) for 2 h, subsequently subjected to H₂O₂ (90 μM) for 4 h. The values were represented as the mean ± SD (n = 3). **P < 0.01 vs. the control group.
4. Discussion

Hydroxy-α-sanshool (HAS) is a promising natural monomer of unsaturated fatty acid amide isolated from the *Z. bungea-num* pericarps with lots of bioactivities, such as hypolipidemic and hypoglycemic effects, improving learning and memory effects. As part of our continuing research on this compound, to the best of our knowledge, the present study provides the first evidence that HAS can protect PC12 cells from H$_2$O$_2$-induced damage through the suppression of apoptosis.

**Figure 6**: Effects of HAS on protein expressions of caspase-3, Bax, Bcl-2, PI3K, p-PI3K, Akt, and p-Akt in H$_2$O$_2$-stimulated PC12 cells. PC12 cells were treated with HAS (15, 30, and 60 μM) or 100 μM vitamin C for 2 h, subsequently subjected to H$_2$O$_2$ (90 μM) for 4 h. Protein expressions of caspase-3, Bax, Bcl-2, PI3K, p-PI3K, Akt, and p-Akt were determined by western blotting, and β-actin was used as the internal reference. The values were represented as the mean ± SD (n = 3). **P < 0.01 vs. the control group.
Previous researches revealed that PC12 cell, a rat photochromogenic cell line, has some neuronal characteristics and similar physiology and pathology of the nerve cells, and in addition, H$_2$O$_2$ possesses high cell membrane transmittance; consequently, H$_2$O$_2$-stimulated PC12 cells commonly considered an ideal cell model for studying pathology and screening candidate drugs of neurodegenerative diseases, such as Alzheimer’s disease (AD) and epilepsy [26–28]. Thus, the PC12 cell line was selected as the experimental cell model in our present study. According to relevant research, many free radicals are generated during the development of neurodegenerative diseases, and some of the reactive oxygen species (ROS) can cause oxidative damage to nerve tissues and eventually lead to apoptosis or even necrosis of neurons [29, 30]. Therefore, ROS play an important role in the apoptosis caused by oxidative stress. As an important member of the ROS family, H$_2$O$_2$ can easily cross cell membranes to generate hydroxyl radicals, which are highly toxic and can cause serious damage to cells and attack biomolecules, ultimately leading to apoptosis or necrosis [31–33]. Therefore, in this study, H$_2$O$_2$ was used to stimulate PC12 cells to simulate the occurrence and development of neurodegenerative diseases caused by oxidative stress. According to CCK-8 assay, after stimulation with H$_2$O$_2$, cell viability of the PC12 cells decreased by 60%; however, pretreatment with HAS reversed the decrease of cell viability induced by H$_2$O$_2$.

For the neurodegenerative diseases, the excessive ROS can lead to direct oxidative damage of molecules, followed by cell dysfunction and apoptosis [5, 34]. Our present investigation found that H$_2$O$_2$ stimulation resulted in excessive ROS accumulation in PC12 cells, and interestingly, HAS pretreatment could decrease the excessive ROS in PC12 cells caused by H$_2$O$_2$. Malondialdehyde (MDA), a product of lipid peroxidation, would be significantly increased when exposed to oxidative stimulation, which is also considered a biomarker of oxidative stress and also causes damage to the cell membrane [22, 23]. In addition, there are various ROS scavenging enzymes in living organisms, among which the most important are the superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GSH-Px). Under physiological conditions, they jointly maintain the redox balance in the body [35]. In vivo, SOD can catalyze the conversion of superoxide anions into H$_2$O$_2$, GSH-Px can reduce toxic peroxides to nontoxic hydroxyl compounds, and CAT can promote the further conversion of H$_2$O$_2$ into oxygen and water [36, 37]. According to our results, H$_2$O$_2$-stimulated PC12 cells produced excessive MDA, accompanied by significantly decreased activity of SOD, GSH-Px, and CAT. Interestingly, pretreatment with HAS can decrease the MAD level whereas it can increase the activities of SOD, GSH-Px, and CAT in stimulated PC12 cells. In previous reports, excessive intracellular ROS produced by mitochondria could also lead to mitochondrial dysfunction through oxidative stress-induced apoptosis, and MMP is a sensitive indicator of mitochondrial function [38, 39]. In our results, after H$_2$O$_2$ stimulation, significant apoptosis and reduced cell survival as well as declined ΔΨ$_{m}$ can be found in PC12 cells. In addition, intracellular ROS accumulation increased after H$_2$O$_2$ stimulation, which further promoted the loss of ΔΨ$_{m}$. Besides, as expected, H$_2$O$_2$-induced cell apoptosis events in PC12 cells can be blocked by pretreatment with HAS. All these results suggested that HAS might be beneficial for protecting H$_2$O$_2$-stimulated PC12 cells from ROS-induced apoptosis.

Currently, increasing evidences have suggested that the PI3K/AKT signal pathway plays a crucial role in cell survival and development as well as ROS-induced cell apoptosis [40, 41]. In addition, the PI3K/AKT pathway shows significant antioxidant activity in central and peripheral neurons and can be considered a potential therapeutic target for neurodegenerative diseases, participating in the cellular protective mechanism of ROS-induced cell damage [39]. AKT is a

**Figure 7:** Effects of PI3K inhibitor LY294002 on the viability of PC12 cells (×100). The PC12 cells were pretreated with LY294002 (20 μM) or not for 1 hour; then cells were treated with HAS (60 μM) for 2 h, subsequently subjected to H$_2$O$_2$ (90 μM) for 4 h. HAS: hydroxy-α-sanshool; Norm.: normal. The values were represented as the mean ± SD (n = 3). **P < 0.01 vs. the control group.
serine/threonine kinase activated by recruitment to the plasma membrane and is a key mediator of PI3K-mediated signal transduction [42, 43]. As is shown in Figure 8, the direct results of PI3K phosphorylation is the phosphorylation of AKT, which further affects the expression of Bcl-2 and Bax proteins. Bcl-2 and Bax are a group of proteins closely related to mitochondrial mediated apoptosis, among which the anti-apoptotic protein Bcl-2 is a channel protein located on the mitochondrial membrane, which can inhibit the proapoptotic effect of Bax [44]. Activated p-AKT increased the expression of Bcl-2 and decreased the expression of Bax. In normal PC12 cells, these entire proteins in this signal pathway would be in a dynamic balance [45]. Our results showed that HAS pretreatment could upregulate the proteins of PI3K/Akt signaling (p-PI3K, Akt, and p-Akt) and antiapoptotic proteins of Bcl-2, whereas it could downregulate the apoptotic proteins (caspase-3 and Bax), compared to the PC12 without HAS treatment.

5. Conclusion
In summary, our study suggested that the hydroxy-α-san-shool (HAS) possesses protective potentials on H₂O₂-stimulated PC12 cells by suppression of oxidative stress-induced apoptosis through the regulation of the PI3K/Akt signal pathway. Our results provide scientific evidences that HAS might be considered in the development of a new drug for treating neurodegenerative diseases related to excessive apoptosis induced by oxidative stress.
