Abstract In this paper, I introduce a new generalization of the concept of an operad, further generalizing the concept of an opetope introduced by Baez and Dolan (1998), who used this for the definition of their version of non-strict $n$-categories. Opetopes arise from iterating a certain construction on operads called the + construction, starting with monoids. The first step gives rise to plain operads, i.e., operads without symmetries. The permutation axiom in a symmetric operad, however, is an additional structure resulting from permutations of variables, independent of the structure of a monoid. Even though we can apply the + construction to symmetric operads, there is the possibility of introducing a completely different kind of permutations on the higher levels by again permuting variables without regard to the structures on the previous levels. Defining and investigating these structures is the main purpose of this paper. The structures obtained in this way are what I call $n$-actads. In $n$-actads with $n > 1$, the permutations on the different levels give rise to a certain special kind of $n$-fold category. I also explore the concept of iterated algebras over an $n$-actad (generalizing an algebra and a module over an operad), and various types of iterated units. I give some examples of algebras over 2-actads, and show how they can be used to construct certain new interesting homotopy types of operads. I also discuss a connection between actads and ordinal notation.

Keywords operads, actads, infinite loop spaces, universal algebra, ordinals

1 Introduction

Operads are a central concept of modern algebraic topology. The term was coined by May [26]. Operads are used as an approach to infinite loop space theory. They are a more streamlined alternative to the PROPs (the commonly used abbreviation PROP stands for “product and permutation category”) of Adams and MacLane, Lawvere theories, and the concepts of Boardman and Vogt. An operad $\mathcal{C}$ consists of sets (or spaces) $\mathcal{C}(n)$ where $\mathcal{C}(n)$ is the set of all the operations in $n$ variables in a type of algebraic structure, which it describes. The basic operations of an operad correspond to substituting the results of operations (in different variables) for the input variables of another operation. One also typically includes a unit (identity) operation and commutativity in the broader sense, which means a symmetric group action by permuting variables. This entire structure is included in May’s original definition of an operad (see [26, Definition 1.1], which also included the assumption that $\mathcal{C}(0) = *$). The concept without commutativity was defined by May [26, Definition 3.12] as non-$\Sigma$ operads. Some authors also speak of
plain operads. In contrast, operads where permuting variables is allowed are sometimes called symmetric operads. Another variant is an $S$-sorted operad (or multicategory), which is defined in the same way as an operad, but with an “object set” $S$.

In the original context of infinite loop space theory, May [26] used the little $n$-cube operad which naturally acts on an $n$-fold loop space. By passing to the limit, an infinite loop space is shown to be an $E_{\infty}$-space, which means an algebra over an operad $C$ where each $C(n)$ is a contractible space with a free $\Sigma_n$-action. This is one way of capturing the notion of a commutative monoid “up to all the possible homotopies”.

In a completely different context, operads also later appeared in algebra, where instead of operations on a set or a space, we axiomatize multilinear operations on a vector space. In this fashion, for example, commutative and associative algebras, as well as Lie and Poisson algebras can be axiomatized. Ginzburg and Kapranov [17] discovered a striking phenomenon of Koszul duality of operads and their algebras, analogous to the previously known concept of Koszul duality of algebras and modules (see [32]).

Passing from vector spaces to their chain complexes, we can also talk about chain-level $E_{\infty}$-operads and their algebras. Hinich and Schechtman [21] noticed that the cochain complex of a topological space has the structure of an $E_{\infty}$-algebra (which they called a May algebra). Mandell [24] proved that for well-behaved spaces (for example, simply connected with finitely generated homotopy groups), their $p$-completed homotopy type can be recovered from their $E_{\infty}$ cochain complex with coefficients in $\mathbb{F}_p$.

In some sense, the ideas of the topological and algebraic contexts are combined in multiplicative infinite loop space theory (see [13, 29]), which generalizes certain structures of multilinear algebra to stable homotopy theory, i.e., to the context of spectra (see [2, Part III]).

Baez and Dolan [3] introduced the $+$-construction (unrelated to Quillen’s $+$-construction), which is a procedure used to pass from monoids to plain operads. Essentially, for an $S$-sorted operad $\mathcal{O}$, there is an operad $\mathcal{O}^+$ sorted over the set of operations of $\mathcal{O}$, whose algebras are operads over $\mathcal{O}$. Applying this procedure to monoids defines plain operads, and iterating defines opetopes, which Baez and Dolan [3] used to axiomatize non-strict $n$-categories. Variants and generalizations of these concepts were introduced by Hermida et al. [18–20], Cheng [8–10] and Palm [30,31]. Additional references include Zawadowski [38–40] and Fiore and Saville [15].

The $+$-construction was further generalized to Cartesian monads by Leinster [23], and interpreted combinatorially by Kock et al. [22], using the calculus of polynomial functors of Gambino and Hyland [16]. An even more conceptual interpretation in this direction was given by Szumiłow and Zawadowski [34–36]. For another approach using syntactic methods, see Curien et al. [12]. Computer implementations of polytopes are given in [14,22].

However, opetopes do not explain how symmetric operads arise from monoids. While the $+$-construction can be applied to symmetric operads, there is an additional possibility of introducing permutations on each higher level by permuting variables without regard to the structures on the previous levels. The interplay of these permutations is the concept I explore in this paper. I call the resulting structures actads. Note that the possibility of permuting variables randomly does not fit within the picture of any reasonable concept of a higher category: it is a truly new element. Perhaps for that reason, actads have so far defied the conceptual approaches described above, and the only rigorous definition I was able to make starts from scratch.

As it turns out, the higher permutations must be handled quite carefully. We must specify a delicate order of variables on the previous levels which must be preserved for the higher permutations to work. Permutations on the different levels cannot just be mixed into an ordinary category, but must form a special kind of $n$-fold category. Because of this, a particularly canonical model of the structure without permutations (which I call plain actads) must be introduced. Plain $n$-actads form a category equivalent to a version of $n$-opetopes (see [3]), a combinatorial model of which was given in [22]. However, we need an ordered model which will be introduced from scratch.

In this paper, I index the actads so that monoids are 0-actads and operads are 1-actads. The operations of an actad are indexed by an $n$-base. The 0-base is just 1 point, and the 1-base is the set of natural numbers. Elements of the 2-base are, roughly speaking, based trees. Drawing, in the place of each node of
a tree, a triangle whose vertex is the node, and whose base contains the successor nodes, one can visualize a 3-base as a tree drawn in this fashion, where each triangle can be, recursively (but only finitely many times), subdivided into a tree drawn in a similar fashion. Remembering all these subdivisions is a key part of the structure of an element of the 3-base. For $n > 3$, $n$-bases are more difficult to visualize.

To explain how the induction procedure works in more detail, I find it easier to first only discuss associativity. I call the concept only encoding associativity a plain actad. Plain actads are not categories, but merely sets. I define a plain $n$-actad using an indexing set $B_n$ called the plain $n$-base. For example, the elements of $B_2$ are planar trees, which means that the successors to each node are linearly ordered. In addition to the $B_n$’s, there are maps $F_n$, which map $B_n$ into the set of non-empty finite sequences in $B_{n-1}$ and $G_n$, which simply maps $B_n$ into $B_{n-1}$. Now, $F_n$’s can be thought of as assigning to an element of $B_n$ the “set of its entries”. For example, $F_2$ can be visualized as giving the degrees of internal nodes of a planar tree. In addition, $G_n$ can be thought of as assigning to an element of $B_n$ its “total arity”, which is an element of $B_{n-1}$. Finally, we can define a composition operation by taking an element $x \in B_n$ and replacing one of its “entries” (i.e., one of the terms $z$ of $F_n(x)$) with some $y \in B_n$ such that $G_n(y) = z$.

For example, we begin with $B_0 = \{\ast\}$ and $B_1 = \mathbb{N}$ (where we identify a natural number $n$ with a planar tree with 1 triangle and $n$ prongs). The composition of $n, m \in \mathbb{N} = B_1$ is then defined to always give $n + m - 1$ and can be visualized in the diagram (2.1) below. Note that we always have

$$F_1(n) = (\ast, \ldots, \ast) \quad \text{and} \quad G_1(n) = \ast \quad \text{for every } n,$$

so all $n, m \in B_1$ are composable in all the ways.

Now, a plain $n$-actad is a system $C(z)$ indexed by $z \in B_n$. The structure of a plain $n$-actad is defined by composition operations in $C$ “fibered over $B_n$”, i.e., where the indices are elements involved in a composition in $B_n$. Finally, we can derive the associativity axioms from associativity properties of the composition in $B_n$.

To advance the induction, I define $B_{n+1}$ as the free plain $n$-actad on $B_n$. In other words, we no longer “execute” the composition operations on $B_n$, but simply keep track of which ones were made, subject to the associativity axiom. In this fashion, we can inductively define $B_n$’s, and thus we can define plain $n$-actads. I treat plain $n$-actads below in Section 2.

Just as in the case of operads, capturing a commutativity axiom complicates the structure substantially. In the case of an operad $\mathcal{C}$, a commutativity property is expressed by introducing a $\Sigma$-action on $\mathcal{C}(n)$. Then this turns $B_1$ into a groupoid $\mathcal{B}_1$, by making $\Sigma_n$ the automorphism group of $n \in \mathbb{N}$. From a philosophical point of view, $n$ really stands for the word

$$a^n = a \cdots a \quad (1.1)$$

in the free monoid on one element $a$, and the permutations interchange (independently of the monoid structure) the $n$ copies of $a$. In this paper, I develop the corresponding additional structure $\mathcal{B}_2$, and eventually $\mathcal{B}_n$. Recall that the elements of $B_2$ are planar trees. $\mathcal{B}_2$ should incorporate the “1-permutations” induced from $\mathcal{B}_1$ by (1.1), which are isomorphisms of trees. Notice that a 1-permutation can change the tree, so it may no longer be an automorphism, although it is always an isomorphism (so 1-permutations form a groupoid). For example, see the picture of a 1-permutation in $\mathcal{B}_2$ in (3.6). But now it seems that any natural generalization should introduce permutations of nodes of the tree of the same arity (call them 2-permutations), regardless of the structure of the tree (just as in (1.1), the permutations are completely independent of the product operation of the free monoid). For example, see (3.7).

We need to answer the question of how the 1-permutations and 2-permutations interact. Putting them both together into a single category seems to fail. In other words, a random permutation of nodes of the same arity in a tree does not seem to induce, in any meaningful way, a permutation on leaves. Nor does there really seem to be a natural structure of a 2-category: both 1-permutations and 2-permutations act on objects. Thus, we are led to a bicategory structure (see [4]), where the $\{1,2\}$-morphisms are permutations of nodes of equal arity, on which we have prescribed the same permutation
of successors. This, fortunately, is a rather special type of bicategory. In addition to the \( \{1\}\)-morphisms and \( \{2\}\)-morphisms (we may in the future omit the braces to simplify notation) forming groupoids, every \( 1\)-morphism and \( 2\)-morphism with the same source together make up a unique \( \{1,2\}\)-morphism. In this paper, I call this type of bicategory cube-like, and generalize it to all \( n \). Then, \( \mathcal{B}_n \) is, in particular, a cube-like \( n\)-fold category. Along with the appropriate axioms expressing compatibility with the composition, this is my implementation of the commutativity axiom. Cube-like \( n\)-fold categories fibered over \( \mathcal{B}_n \) with the composition satisfying the properties of \( \mathcal{B}_n \)’s composition are what I call \( n\)-actads. I treat this in Section 3.

The question of units is another issue. There is, of course, a natural concept of unit that can be considered a part of associativity, which generates two unit axioms. However, there is more to the story. Even in operads (which, recall, are \( 1\)-actads), we encounter another concept, namely that of a based operad, which also contains a manifestation of the unit of a monoid (which is a 0-actad). More precisely, a based operad \( \mathcal{C} = (\mathcal{C}(n)) \) is indexed by \( n \in \mathbb{N}_0 \), and we are given a base point \( * \in \mathcal{C}(0) \). Based operads play a crucial role in infinite loop space theory (for example, in the approximation theorem [26]).

Similarly, for \( n\)-actads, beside the “ordinary” unit notion there is a notion which includes carry-overs from \( k\)-actad units for \( k < n \). I call this “recursive” unit axiom \( R\)-unitality. It is interesting to note that in the case of \( n\)-actads, the commutativity axiom becomes substantially richer in the \( R\)-unital case. This is because for \( n \geq 3 \), in the non-unital case, an element of an \( n\)-actad can be only non-trivially composed with elements of lower arity, with which it cannot be permuted by an \( \{n\}\)-morphism. In the \( R\)-unital context, this is not necessarily the case. I treat the \( R\)-unital case in Section 7 below.

The original application of operads comes from their algebras. In addition, the notion of algebras prompted the notion of a module over an operad and its algebras, which was invented by May [26], and is treated, for example, in [5]. We would like to generalize these notions to \( n\)-actads. Indeed, there are directly analogous notions for \( n\)-actads, and I treat these concepts in Section 4. An important example is the commutative (in the narrower sense) \((n+1)\)-actad \( \mathcal{A}_{n+1} \) whose algebras can be thought of as strictly commutative \( n\)-actads. By “freeing up” the \((n+1)\)-morphisms, we are able to obtain the associative \((n+1)\)-actad \( \mathcal{A}_{n+1} \), whose algebras are precisely \( n\)-actads.

For \( n \geq 2 \), the immediate thought is that this idea should be “iterated”. However, implementing that idea is not obvious. Before we can iterate, we must for example answer the question of what happens to \( n \) in the iterated algebras. The answers to these questions are given in Section 6, and are summarized as follows.

For an \( n\)-actad \( \mathcal{C} \), it turns out that there exists a notion of an iterated \( \mathcal{C}\text{-I}\)-algebra for every subset \( I \subseteq \{0, \ldots, n\} \), which consists of \(|I|\) cube-like \((n-1)\)-fold categories. An axiomatization of these notions is made by using multisorted algebras (a definition of which can be found in [6]). The concept essentially allows one to label the entries of a tree with the elements of \( I \) (for example, see (6.1)). In the cases of \( I = \{0\} \) and \( I = \{0, n\} \), the concept gives the notions of algebras and modules, respectively. I treat this in Section 6.

What are some interesting examples and applications of \( n\)-actads? So far, we have been working in the ground category of sets when discussing actads and their algebras. One can of course also work with spaces or simplicial sets without any difficulties (as is done with operads in [26]). This is where one may expect the most interesting topological examples to reside. At present, finding such examples is restricted by the fact that, for \( n \geq 2 \), the structures are unfamiliar, but we do present some examples of the new structure here. One interesting example is the \( E_{\infty}\text{-n-actad } \mathcal{A}_n \), which is the \( \check{C}ech \) resolution of the associative \( n\)-actad \( \mathcal{A}_n \). Note that since we have a canonical map of \( n\)-actads

\[
\mathcal{A}_n \to E\mathcal{A}_n,
\]  

\( E\mathcal{A}_n \)-algebras are, in particular, \((n-1)\)-actads.

For \( n = 2 \), I give some concrete examples related to this case. I describe the free \( E\mathcal{A}_2 \)-algebra \( A_{E\mathcal{A}_2}(X_2) \) on the groupoid \( X_2 \) fibered over \( \mathcal{B}_2 \), where \( X_2(2) \) is the groupoid given by \( S_2 \) acting on itself freely and \( X_2(n) \) is empty over \( n \neq 2 \). I also give a sufficient condition for the classifying space of a groupoid to be algebras over the operad \( A_{E\mathcal{A}_2}(X_2) \). In some sense, this is an analogue of the result of May [28] that
the classifying space of a permutative category is an algebra over the Barratt-Eccles $E_\infty$-operad, which is $E\mathcal{S}_2$.

In Section 9, I actually construct $E\mathcal{S}_2$-algebras which are new operads (in the sense that they, as far as I know, are not equivalent to operads which have been previously studied). For a spectrum $E$ (see [2] for an introduction of the concept of spectra in algebraic topology) with a map $E \to H\mathbb{Z}$ (the Eilenberg-Mac Lane spectrum), we can obtain a map of $E_\infty$-spaces $E_0 \to \mathbb{Z}$. I show that this structure (also when $E_0$ is replaced with any $E_\infty$-space), in particular, leads to a structure of an $E\mathcal{S}_2$-algebra, and show that in certain cases, the resulting example is non-trivial even as an operad (via (1.2)), in the sense that an $E_\infty$-operad does not map into it.

In fact, algebras over a based version $\Xi_{E_0}$ of this operad can be characterized as follows: for a map of spectra $E \to F \to H\mathbb{Z}$, let $\psi : F_0 \to \mathbb{Z}$ be the corresponding map of $E_\infty$-spaces. Then $\Xi_{E_0}$-algebras are canonically equivalent to spaces of the form $\psi^{-1}(-1)$. Note that $\psi^{-1}(-1)$ is homotopy equivalent to $\psi^{-1}(0)$, which is an infinite loop space, but the homotopy equivalence is non-canonical when the map of spectra $E \to H\mathbb{Z}$ does not split.

While this is only one example of a homotopical structure obtained from the 2-morphisms of actads, its non-triviality can be thought of as higher-categorical in nature (since it comes from a lack of canonicity). Thus, our example may provide a clue to the nature of the kinds of applications the new structure of an $n$-actad may have.

There is yet an entirely different aspect of the story of plain actads. Kock et al. [22] discussed a machine interpretation and also a “fixed point” of the $\psi$-construction. It is possible to pursue this further. Our particular model of plain actads suggests a close connection with the Veblen hierarchy of ordinal notation. From this point of view, it is possible to iterate the opetope construction transfinitely and we show that the level of complexity of the first fixed point of that construction is the Feferman-Schütte ordinal $\Gamma$.

More specifically, recalling the fact that the elements of $B_2$ can be identified with planar trees, one is reminded of the Veblen hierarchy of ordinals, where, if we let $\varphi_\beta$ denote the Veblen functions (see [37]), $\varphi_1(\alpha) = \omega^\alpha$ and $\varphi_\beta(\alpha)$ is the $\alpha$-th fixed point of $\varphi_\beta$ for $\beta' < \beta$. (This is shifted by 1 from the usual convention, which is more natural from my point of view. The shift disappears for $\beta \geq \omega$.) The first fixed point of this hierarchy (the first ordinal with $\varphi_1(0) = \Gamma$) is the Feferman-Schütte ordinal $\Gamma$ (see [37]). It is particularly well known that trees can be used for the notation of ordinals below $\varepsilon = \varphi_2(0)$ which suggests a connection with plain actads. In Section 11, I indeed construct an onto function

$$B_n \to \varphi_n(0).$$

This prompts the idea of generalizing $B_n$ to the case where $n$ is an ordinal, which is carried out readily. Thus, we can also use $B_\alpha$ for $\alpha < \Gamma$, as notation for countable ordinals below $\Gamma$. The map I constructed is not a bijection (for example even for trees, we have $1 + \omega = \omega$). This could be remedied by taking a proper subset of $B_n$, but we do not undertake this task in the present paper. Since actads are algebraic structures, even the map (1.3) adds to visualization of ordinals between $\varepsilon$ and $\Gamma$.

2 Plain bases and actads

In this section, we introduce plain actads. By the results of [22] (following the concept of Gambino and Hyland [16]), the category of plain $n$-actads is equivalent to $n$-operads without units (a unital version of this statement also holds (see Section 7)). However, plain actads give a canonical ordered model of the category which we need when introducing actads. As we described in Section 1, in the process of defining plain $n$-actads, we must also define the plain $n$-base and the maps $F_n$’s and $G_n$’s. We define a set $B_n$, also called the plain $n$-base and plain $n$-actads inductively. Plain $n$-actads are universal algebras sorted on $B_n$.

In general (see [6]), for a set $S$, an $S$-sorted universal algebra is defined to be the collection of the data of a set $X$ with a map $X \to S$ together with a set $O_n$ for each $n \geq 0$ of $n$-ary operations (specific to the type of algebra we are considering) together with a map $O_n \to S^{n+1}$ (specifying which operations
are allowed with the given sources and target), that is required to satisfy certain prescribed identities (also specific to the kind of algebra considered), where in compositions, the output of an operation is plugged into an input over the same \( s \in S \) (i.e., compositions are \( O_n \times S^n \rightarrow 0_{k_1} \times \cdots \times O_{k_n} \rightarrow O_{k_1 + \cdots + k_n} \)). Homomorphisms of a given kind of \( S \)-sorted algebras are maps over \( S \) (i.e., commuting with the given maps to \( S \)) which are compatible with the operations. For example, a group acting on a set forms a \( S \)-sorted universal algebra by allowing those operations and identities which are allowed after \( f \) is applied. For a finitary monad \( M \) in \( \text{Set} \), \( M \) is its right adjoint, given by \( M(X) = \text{colimit in } \text{Set} \) of \( M(K) \rightarrow S \) with \( K \subseteq X \) finite.

For a map \( f : S \rightarrow T \), a \( T \)-sorted algebra specifies an \( S \)-sorted algebra by allowing those operations and identities which are allowed after \( f \) is applied. For a finitary monad \( M \) in \( \text{Set} / T \), we can describe the monad \( f_* M \) in \( \text{Set} / S \) as \( RML \) where \( L : \text{Set} / S \rightarrow \text{Set} / T \) is the forgetful functor and \( R : \text{Set} / T \rightarrow \text{Set} / S \) is its right adjoint, given by \( R(X) = X \times_T S \). In particular, an unsorted universal algebra can be made \( S \)-sorted by pulling back along the map \( S \rightarrow * \). Thus \( S \)-sorted operads (or multicategories) are defined. Of course, in multicategories, we often consider multifunctors, which are more general morphisms over a map of sets \( S_1 \rightarrow S_2 \) preserving the operations in the obvious sense. In general, for an \( S \)-sorted universal algebra pulled back via a map \( f : S \rightarrow T \), we have a notion of a morphism over any map \( S_1 \rightarrow S_2 \) over \( T \).

Plain \( n \)-actads are universal algebras sorted in \( B_n \), which means that a plain \( n \)-actad is a set \( X \) over \( B_n \) (i.e., a map \( X \rightarrow B_n \)) with certain operations (which, as it will turn out, are binary) applicable to elements that are mapped to certain elements of \( B_n \), specific to the operation, and certain identities among iterated operations. For \( n = 0 \), the plain 0-base is just a point:

\[
B_0 = \{ * \}.
\]

To describe the operations in more detail, we must also say more about the maps. For \( n \geq 1 \), the additional structure on \( B_n \) is needed, which we define inductively. Write

\[
T_{B_{n-1}} = \{ (a_1, \ldots, a_k) \mid a_i \in B_{n-1}, k \geq 1 \}.
\]

We have maps

\[
F_n : B_n \rightarrow T_{B_{n-1}}
\]

(\( m_x \) be the length of the sequence \( F_n(x) \) for \( x \in B_n \), and write \( F_n(x) = (f_1(x), \ldots, f_{m_x}(x)) \)) and

\[
G_n : B_n \rightarrow B_{n-1}.
\]

Suppose that \( B_{n-1} \) and \( (n - 1) \)-actads have already been defined. We then have the following structure: we have an operation

\[
x \circ^n y
\]

for \( x, y \in B_n \), \( 1 \leq i \leq m_x \), and \( G_n(y) = f_i(x) \), such that

\[
m_x \circ^n y = m_x + m_y - 1.
\]

To illustrate what we are after, before making exact definitions, let us consider what these structures look like for \( n = 0, 1, 2 \). For \( n = 0 \), \( B_0 \) only consists of a single point, so one can only compose an element with itself leading to the picture that is not very interesting:

\[
\bullet
\]

However, for \( n = 1 \) and \( n = 2 \), the pictures are much more revealing. I will use the following pictures to express 1- and 2-compositions. For \( n = 1 \), \( B_1 \) is the set of all natural numbers, and we see the standard
composition picture for planar trees (identifying a natural number $n$ with the planar tree with $n$ prongs). Here, we are replacing one of the “prongs” of a planar tree at the end of one of the trees with the “stem” of a different tree. The “prongs” are visualized in a “left to right” order.

$$x \circ y.$$  

(2.1)

It is important to note that, for operads, any two trees can be composed. This is because for every tree $x$, we have $G_1(x) = *$ and $F_1(x) = (*, \ldots, *)$. So for every $1 \leq i \leq m_x$, $f_i(x) = G_1(x) = *$. So for every two trees, every possible $f_i$ will agree with $G_1$.

For $n = 2$, though, the composition is quite different. In the picture, I express the 2-composition by putting a tree with the same arity inside one of the “triangles”. Letting

$$x = \begin{array}{c} 1 \\ 2 \\ \vdots \end{array}, \quad y = \begin{array}{c} 1 \\ 2 \end{array}$$

(where the numbers denote the ordering of the entries of $x$ and $y$), we can compose the two trees via $x \circ^2 y$ (see the below picture)

The induction data of $B_n$ also includes increasing functions

$$\phi^{(x,y)}_n : \{1, \ldots, m_x\} \setminus \{i\} \to \{1, \ldots, m_x + m_y - 1\},$$

$$\psi^{(x,y)}_n : \{1, \ldots, m_y\} \to \{1, \ldots, m_x + m_y - 1\}$$

expressing how the elements of the two objects of $B_n$ involved in the composition are shuffled in the resulting object. The purpose of these functions is to formulate an analogue of the associativity axiom.
For example, we see that for $n = 1$, where the elements are prongs, the prongs of $y$ “stay together” in the shuffle even though the indexing is shifted. For $n = 2$, instead of prongs, the elements are triangles. They are also ordered “left to right” (and in the case of a tie, “top to bottom”), but we see that in this ordering, both shuffles $\varphi$ and $\psi$ are non-trivial, i.e., the “triangles” of $y$ do not “stay together” after the composition.

The associativity property for the composition we require states that for $1 \leq i < j \leq m_x$ and $G_n(z) = f_j(x)$,

$$\left( x \circ_n^i y \right) \circ_n^{i,j}(y)(j) z = (x \circ_n^i z) \circ_n^j y. \quad (2.2)$$

For $n = 1$, we have

$$\varphi_1^{(x,i,y)}(j) = j + m_y - 1 \text{ for } i < j \leq m_x,$$

$$\psi_1^{(x,i,y)}(j) = j + i - 1 \text{ for } 1 \leq j \leq m_y. \quad (2.3)$$

To make a rigorous definition of plain $n$-actads, we need to formulate a few more properties of the composition and these functions. For $j < i$, we must have

$$\varphi_n^{(x,i,y)}(j) = j. \quad (2.4)$$

(We shall sometimes omit the subscript $n$ when it is clear.) We also have, for $i < j < k$ and any $n$, the additional axioms

$$\psi_n^{(x,i,y)}(j) = \varphi_n^{(x,a_1,i,y)}(j) \quad (2.5)$$

Suppose that we have defined $B_n$ (and all the associated structure).

**Definition 2.1.** A plain $n$-actad has the data of a set $C$ with a map

$$C \to B_n,$$

and, if we write $C(x)$ for the inverse image of an element $x \in B_n$, composition operators

$$\gamma_{n,i} : C(x) \times C(y) \to C(x \circ_n^i y)$$

for $x, y \in B_n$ satisfying $1 \leq i \leq m_x$ and $G_n(y) = f_j(y)$. We require that these composition operators satisfy the condition that for $1 \leq i < j \leq m_x, z \in B_n$ and $G_n(z) = f_j(x)$, the following diagram commutes:

$$C(x) \times C(y) \times C(z) \xrightarrow{\gamma_{n,i} \times \text{Id}} C(x \circ_n^i y) \times C(z)$$

$$\xrightarrow{T} C(x) \times C(z) \times C(y) \xrightarrow{\gamma_{n,j} \times \text{Id}} C(x \circ_n^j z) \times C(y)$$

$$\xrightarrow{\gamma_{n,j} \times \text{Id}} C(x \circ_n^j z) \times C(y) \xrightarrow{\gamma_{n,i}} C((x \circ_n^i y) \circ_n^{i,j}(y)(j) z) \quad (2.5)$$

where $T : C(x) \times C(y) \times C(z) \to C(x) \times C(z) \times C(y)$ is the permutation switching the coordinates of $C(z)$ and $C(y)$. (We shall also sometimes write $\gamma_i$ instead of $\gamma_{n,i}$ when the value of $n$ is clear.)

We shall now inductively define $B_n$. For $n = 1$, let $B_1 = \mathbb{N}$. In addition, define

$$F_1 : B_1 \to \{(a_1, \ldots, a_k) \mid a_i \in B_0 = \{\ast\}\},$$

$$F_1 : B_1 \to \{(a_1, \ldots, a_k) \mid a_i \in B_0 = \{\ast\}\},$$
for every $i$. We have a canonical map 

$$G_1 : B_1 \rightarrow B_0$$

by

$$F_1(n) = \{*, *, \ldots, *\}, \quad G_1(n) = \{*\}.$$ 

Then for $x, y \in B_1$, let 

$$x \circ^1_1 y = x + y - 1.$$ 

Note again that this works for every $i$ because the coordinates of $F_1(x)$ are all $*$, and 

$$G_1(y) = *$$

for every $y$.

Suppose that we have $B_n$ and all the maps associated with it. By Definition 2.1 above, we have the notion of plain $n$-actads. Given this, define 

$$B_{n+1} = \{(x_1, x_2, \ldots, x_{k}) \mid k \geq 1, x_i \in B_n, \quad G_n(x_i) = f_{ij-1}(\cdots (x_1 \circ^0_{i_1} x_2) \circ^0_{i_2} x_3 \cdots) \circ^0_{i_{j-2}} x_{j-1}), \\ 1 \leq i_j \leq m_{\cdots ((x_1 \circ^0_{i_1} x_2) \circ^0_{i_2} x_3 \cdots) \circ^0_{i_{j-2}} x_{j-1}} = m_{x_1} + \cdots + m_{x_j} - (j - 1), \\ i_1 \leq i_2 \leq \cdots \leq i_{k-1}\}. $$

In addition, define 

$$G_{n+1}((x_1, x_2, \ldots, x_{k}), (i_1, i_2, \ldots, i_{k-1})) = (\cdots ((x_1 \circ^0_{i_1} x_2) \circ^0_{i_2} x_3) \cdots) \circ^0_{i_{k-1}} x_{k},$$

$$F_{n+1}((x_1, x_2, \ldots, x_{k}), (i_1, i_2, \ldots, i_{k-1})) = (x_1, x_2, \ldots, x_{k})$$

and 

$$m((x_1, x_2, \ldots, x_{k}), (i_1, i_2, \ldots, i_{k-1})) = k.$$ 

Then we have the following lemma.

**Lemma 2.2.** $B_{n+1}$ is the free plain $n$-actad on $\text{Id} : B_n \rightarrow B_n$, where 

$$(x_1, x_2, \ldots, x_{k}), (i_1, i_2, \ldots, i_{k-1}) = \gamma_{n,i_{k-1}}(\gamma_{n,i_{k-2}}(\cdots \gamma_{n,i_2}(\gamma_{n,i_1}(x_1, x_2), x_3), x_4) \cdots, x_{k}).$$

**Proof.** The free plain $n$-actad on $B_n$ is 

$$T_n = \{\gamma_{n,i_1}(\gamma_{n,i_2}(\cdots \gamma_{n,i_2}(x, y_k), \ldots, y_2), y_1) \mid i_k, \ldots, i_1 \in \mathbb{N}, \\ x, y_1, \ldots, y_k \in B_n \text{ composable}\}/\sim,$$

where $\sim$ is the smallest equivalence relation containing compositions of $\gamma$'s differing only in one pair of consecutive $\gamma$'s, replaced by another according to the diagram (2.5). We have, by definition,

$$B_{n+1} = \{\gamma_{n,j_1}(\gamma_{n,j_2}(\cdots \gamma_{n,j_k}(x, x_k), \ldots, x_2), x_1) \mid j_k \leq \cdots \leq j_1, \\ x, x_1, \ldots, x_k \in B_n \text{ composable}\}.$$ 

We want 

$$B_{n+1} = T_n.$$ 

We have a canonical map 

$$B_{n+1} \rightarrow T_n.$$ 

Suppose $i < j$. Then we have, by the diagram (2.5), 

$$\gamma_i(\gamma_j(x, z), y) = \gamma_{\gamma^{(x,i)}_{n,i,j}^{(x,j)}(y)}(\gamma_i(x, y), z).$$
and $\varphi_n^{(x,i,y)}(j) \geq j > i$. So for every
\begin{equation}
\gamma_n, i_1, \gamma_n, i_2, (x, y_k, \ldots, y_2), y_1) \in T_n,
\end{equation}
we can use $\varphi_n^{(x,i,y)}(i_\ell+1)$ to “switch” the order of $i_\ell$ and $i_\ell$ whenever $i_\ell < i_{\ell+1}$. So there exist $j_1 \geq \cdots \geq j_k$ such that
\begin{align*}
\gamma_n, i_1, \gamma_n, i_2, (x, y_k, \ldots, y_2), y_1) \\
= \gamma_n, j_1, \gamma_n, j_2, (x, y_{\sigma(k)}, \ldots, y_{\sigma(2)}, y_{\sigma(1)}),
\end{align*}
where $\sigma$ is a suitable permutation. Though we note that it is not necessarily true that \{i_1, \ldots, i_k\} = \{j_1, \ldots, j_k\}, this gives a left inverse of (2.6), so (2.6) is onto. However, then we need to know that we get the same answer regardless of the order of “switches”. In the proof of this, the axioms (2.3) and (2.4) will come into play.

Suppose $i < j < k$. Performing switches in two different ways, we get
\begin{align*}
\gamma_i(\gamma_j(\gamma_k(x, t), z), y) &= \gamma_i(\gamma_j^{(x,j-1,i,y)}(j)(\gamma_k(x, t), z)) \\
&= \gamma_i(\gamma_j^{(x,j-1,i,y)}(j)(\gamma_i(x, y), t, z)) \\
&= \gamma_i(\gamma_j^{(x,j-1,i)y}(j)(\gamma_i(x, y), t, z), t)
\end{align*}
and
\begin{align*}
\gamma_i(\gamma_j(\gamma_k(x, t), z), y) &= \gamma_i(\gamma_j^{(x,j-1,i,y)}(j)(\gamma_j(x, z), t), y) \\
&= \gamma_i(\gamma_j^{(x,j-1,i,y)}(j)(\gamma_i(x, z), t), y) \\
&= \gamma_i(\gamma_j^{(x,j-1,i,y)}(j)(\gamma_i(x, z), t), t).
\end{align*}
Thus, we must have
\begin{align*}
\varphi_n^{(x,i,y)}(\gamma_j^{(x,j-1,i,y)}(j)(k)) &= \varphi_n^{(x,i,y)}(\gamma_j^{(x,j-1,i,y)}(j)(\gamma_i(x, t), z)(k)), \\
\varphi_n^{(x,i,y)}(j) &= \varphi_n^{(x,i,y)}(\gamma_i(x, t), z)(j),
\end{align*}
which are (2.3) and (2.4). Conversely, (2.3) and (2.4) guarantee that two switches have the same result, i.e.,
\begin{align*}
\varphi_n^{(x,i,y)}(\gamma_i(x, t), z)(k) &= \varphi_n^{(x,i,y)}(\gamma_i(x, t), z)(k).
\end{align*}

Now, we use induction to prove that we always get the same result regardless of the order we perform switches of consecutive pairs $\gamma_i \gamma_j$ for $i < j$. Let $i = \min\{i_1, \ldots, i_k\}$, where $i_1, \ldots, i_k$ are as in (2.7). If $i$ occurs only once in the sequence $(i_1, \ldots, i_k)$, then let $n_i$ be the distance from $i$ to the end of the sequence. If there exist $\ell_1 < \cdots < \ell_m \in \{1, \ldots, k\}$ such that $i = i_{\ell_1}, \ldots, i_{\ell_m}$, then let $n_i$ be the distance from $i_{\ell_m}$ to the end of the sequence.

If $i$ is at the end of the sequence (i.e., $i = i_k$ and $n_i = 0$), then repeat this process for $(i_1, \ldots, i_{k-1})$. If the smallest $i$ in every sequence is at the end, $(i_1, \ldots, i_k)$ is already in order. So, then we are done.

Suppose that we know that the result is independent of the order we take the switches if $n_i = p$. Then suppose $n_i = p + 1$.

The strategy is to show that without loss of generality, all the possible switches from $j < k$ to $j > k$ to the right of $i$ can be done first before $i$ is moved to the right. Then the order of the switches to the right of $i$ does not matter by the induction hypothesis.

First, let us consider the position when the last switch to the right of $i$ before $i$ is moved to the right has been performed. Assume first that the situation immediately to the right of $i$ is
\begin{equation}
i < j > k.
\end{equation}
Thus, the next position will be
\[ j' > i < k. \] (2.12)

Now if any more switches to the right of \( i \) happen before \( i \) is moved again, then equivalently, those switches could have been made first, followed by the move from (2.11) to (2.12).

Thus, either all the possible switches to the right of \( i \) have been performed before (2.11) was reached (which is what we were trying to assume), or the position right before \( i \) was moved to the right was
\[ i < j < k. \] (2.13)

Now \( i \) is moved to the right producing
\[ \bar{j} > i < k. \]

By the induction hypothesis, the order of the remaining moves does not matter, so we may as well continue to
\[ \bar{j} < \bar{k} > i, \]
\[ \bar{k} > \bar{j} > i. \]

But by axioms (2.3) and (2.4), those are equivalent to
\[ i < k' > j, \]
\[ k'' > i < j, \]
\[ k'' > j'' > i. \] (2.14)

In the sequence (2.14), one more move was executed to the right of \( i \) before \( i \) was moved. \( \square \)

Note that this proof is analogous to the proof of the presentation of \( \Sigma_n \) by the “Yang-Baxter relations”
\[ a_i a_{i+1} a_i = a_{i+1} a_i a_{i+1} \]
(along with \( a_i a_j = a_j a_i \) for \( j > i + 1 \), where \( a_i = (i, i + 1) \) in the cycle notation.

Then the functions \( \varphi^{(x,j,y)}_{n+1} \) and \( \psi^{(x,j,y)}_{n+1} \) for
\[ x = ((x_1, x_2, \ldots, x_k), (i_1, i_2, \ldots, i_{k-1})) \]
\[ y = ((y_1, y_2, \ldots, y_\ell), (\iota_1, \iota_2, \ldots, \iota_{\ell-1})) \]
are determined as follows.

For a plain \( n \)-actad \( C \), and for \( \zeta_s \in C(x_s) \) and \( \zeta_t \in C(y_t) \), we have
\[ \gamma_{n,i_{k-1}}(\cdots \gamma_{n,i_j} \gamma_{n,i_{j-1}}(\cdots \gamma_{n,i_2} \gamma_{n,i_1}(\zeta_1, \zeta_2), \zeta_3), \ldots, \zeta_{j-1}), \]
\[ \gamma_{n,i_{\ell-1}}(\cdots \gamma_{n,i_2} \gamma_{n,i_1}(\zeta_1, \zeta_2), \zeta_3), \ldots, \zeta_{\ell-1})) \]
\[ = \gamma_{n,\lambda_{k+\ell-1}}(\cdots \gamma_{n,\lambda_2} \gamma_{n,\lambda_1}(\mu_1, \mu_2), \mu_3), \ldots, \mu_{\lambda_{k+\ell-1}}) \]
with
\[ \lambda_1 \leq \cdots \leq \lambda_{k+\ell-1}, \]
\[ \zeta_s = \mu_{\varphi^{(x,j,y)}_{n+1}(s)}, \]
\[ \zeta_t = \mu_{\psi^{(x,j,y)}_{n+1}(t)} \]
for \( s \in \{1, \ldots, k\} \) and \( t \in \{1, \ldots, \ell\} \). Finally, also define
\[ ((x_1, \ldots, x_k), (i_1, \ldots, i_{k-1})) \circ_{J}^{n+1} ((y_1, \ldots, y_\ell), (i_1, \ldots, i_{\ell-1})) \]
\[ = \gamma_{n,i_{k-1}}(\cdots \gamma_{n,i_j} \gamma_{n,i_{j-1}}((x_1, \ldots, x_k), (i_1, \ldots, i_{k-1}))), \]
\[
((y_1, \ldots, y_t), (t_1, \ldots, t_{t-1})), x_{j+1}, \ldots, x_k).
\] (2.15)

Axioms (2.2) and (2.3) then follow from the fact that one can similarly define, directly analogously, a composition of \(((x_1, \ldots, x_k), (i_1, \ldots, i_{k-1}))\) with two appropriate elements

\[
((y_1, \ldots, y_t), (t_1, \ldots, t_{t-1}))
\]

and

\[
((z_1, \ldots, z_{t_2}), (\kappa_1, \ldots, \kappa_{t_2-1}))
\]

at \(1 \leq j_1 < j_2 \leq m_x\). Observe that it is equal, by definition, to the compositions in the two different orders, and similarly for the shuffles.

Axiom (2.4) follows from the fact that by Lemma 2.2, applying composition at a \(j\), as in (2.15), does not affect the shuffles of compositions at \(j' < j\).

### 3 Actads and bases

Using the material of the previous section, we shall now define the \(n\)-base \(B_n\), and then \(n\)-actads. Unlike \(B_n\)'s, \(B_n\)'s are not sets. \(B_n\) and \(n\)-actads are \(n\)-fold categories. (Recall that these are more general than \(n\)-categories. For example, \(n = 2\) gives the notion of bi-categories (see [4]), which strictly contains the notion of 2-categories.) One can define an \(n\)-fold category inductively as a category internal in \((n-1)\)-fold categories (i.e., where both objects and morphisms are \((n-1)\)-fold categories, and the maps involved in the axioms of the category are morphisms of \((n-1)\)-fold categories, i.e., \((n-1)\)-fold functors). We start the induction with 1-fold categories. Note that \(n\)-fold categories still have pullbacks.

This means that it involves sets of “S-morphisms” for \(S\), any subset of \(\{1, \ldots, n\}\). In particular, “\(\emptyset\)-morphisms” are actually the objects, which for \(B_n\) are the plain \(n\)-bases, and for \(n\)-actads, they are the plain \(n\)-actads. To discuss this further, let us introduce some notation.

Suppose that \(C\) is an \(n\)-fold category and \(S \subseteq \{1, \ldots, n\}\). For

\[
\mathbb{I} : S \to \{0, 1\},
\] (3.1)

we have the source-target map

\[
\mathcal{I}_C : S - \text{Mor}(C) \to (\emptyset - \text{Mor}(C)) =: \text{Obj}(C).
\] (3.2)

(Then \(0\) stands for the source and \(1\) stands for the target.) In addition, let \(\mathbb{0} : S \to \{0, 1\}\) be the constant \(0\) function.

More generally, for \(T \subseteq S\) and \(\mathbb{I} : S \setminus T \to \{0, 1\}\), we have a source-target map

\[
\mathcal{I}_T : S - \text{Mor}(C) \to T - \text{Mor}(C).
\]

Call an \(n\)-fold category \(C\) cube-like if for all \(S \subseteq \{1, \ldots, n\}, x \in \text{Obj}(C)\) and

\[
\phi_i \in \{i\} - \text{Mor}(C)
\]

(for any \(i \in S\)) such that \(\mathcal{I}_0(\phi_i) = x\), there exists a unique \(\phi \in S - \text{Mor}(C)\) such that \(\mathcal{I}_0^\{i\}(\phi) = \phi_i\).

Being cube-like is a very substantial restriction on \(n\)-fold categories, essentially still a concept of \((1\)-fold\) categories, since the condition only involves morphisms between objects. In this paper, all \(n\)-fold categories we will deal with will be cube-like, unless specified otherwise. Also, in all of our examples of cube-like \(n\)-fold categories, the 1-subcategories of \(\{i\}\)-morphisms will be groupoids. We shall call such cube-like categories invertible cube-like. In particular, \(B_n\) and the \(n\)-actads will be invertible cube-like \(n\)-fold categories. An \(n\)-fold functor \(F : C \to D\) is called fibered if for every \(x \in \text{Obj}(C)\), and for every \(\phi \in S - \text{Mor}(D)\) with \(\mathcal{I}_0(\phi) = F(x)\), there exists a unique \(\psi \in S - \text{Mor}(C)\) such that \(\mathcal{I}_0(\psi) = x, F(\psi) = \phi\), and all \(S\)-morphisms of \(C\) are given in this way. (Note that other variants of this concept exist.)

Also, we have the following definition.
Definition 3.1. Define the category $I$ by
\[
\begin{align*}
\text{Obj}(I) &= \{0, 1\}, \\
\text{Mor}(I) &= \{(0 \to 0), (0 \to 1), (1 \to 1)\}.
\end{align*}
\]

Then let $\text{Set}_{(n)}$ be the $n$-fold category of sets, defined as follows: for a subset $S \subseteq \{1, \ldots, n\}$, let the set of $S$-morphisms be
\[
S - \text{Mor}(\text{Set}_{(n)}) = \{F \mid F \text{ is a functor } I^S \to \text{Set}\}.
\]

Now, we have a lemma.

Lemma 3.2. (1) Let $\mathcal{D}$ be an $n$-fold category. A fibered $n$-fold functor $F : \mathcal{C} \to \mathcal{D}$ produces (in a bijective fashion) an $n$-fold functor $\Phi : \mathcal{D} \to \text{Set}_{(n)}$: for some $S \subseteq \{1, \ldots, n\}$ and $\psi \in S - \text{Mor}(\mathcal{D})$,
\[
\Phi(\psi)(i) = \mathcal{D}(F^{-1}(\psi))
\]
(recall (3.1) for the definition of $\mathcal{I}$) with
\[
\Phi(\psi) : \text{Mor}(I^{|S|}) \to \text{Mor}(\text{Set})
\]
defined by the fibered property of $F$.

(2) If $F : \mathcal{C} \to \mathcal{D}$ is a fibered $n$-fold functor and $\mathcal{D}$ is cube-like, then $\mathcal{C}$ is cube-like.

Proof. First, we discuss (1). Starting with a fibered $n$-fold functor $F : \mathcal{C} \to \mathcal{D}$, we define $\Phi$ by (3.3). Then the fact that $\Phi$ is an $n$-fold functor follows directly from the properties of the composition in an $n$-fold category.

Given an $n$-fold functor $\Phi : \mathcal{D} \to \text{Set}_{(n)}$, define, for $S \subseteq \{1, \ldots, n\}$,
\[
S - \text{Mor}(\mathcal{C}) = \bigsqcup_{\psi \in S - \text{Mor}(\mathcal{D})} \Phi(\psi)
\]
(3.4)
with $F : \mathcal{C} \to \mathcal{D}$ given by projection. Then $F$ is a fibered $n$-fold functor by the functoriality properties of $F$. Additionally, the constructions of $\Phi$ from $F$ and $F$ from $\Phi$ are obviously inverse to each other.

(2) is immediate from (3.4), since in a fibered $n$-fold functor, for $S \subseteq \{1, \ldots, n\}$, we can lift the $\{i\}$-morphisms with $i \in S$ with a common source uniquely to $\{i\}$-morphisms with a given common source, which then uniquely make up an $S$-morphism both downstairs and upstairs.

We also need a way to construct an $n$-fold category from sequences of morphisms of an $(n-1)$-fold category for the induction step from $\mathcal{B}_n$ to $\mathcal{B}_{n+1}$. (This is a generalization of $T_{B_{n-1}}$ from the case of plain $n$-actads and $n$-bases.)

Definition 3.3. Suppose that $C$ is an $(n-1)$-fold category. Define the $n$-fold category $T_C$ in the following way: suppose $S \subseteq \{1, \ldots, n-1\}$. Then define the $S$-morphisms by
\[
S - \text{Mor}(T_C) = \{(\alpha_1, \ldots, \alpha_k) \mid k \geq 1, \alpha_i \in S - \text{Mor}(C)\}
\]
and
\[
(S \cup \{n\}) - \text{Mor}(T_C) = \{f = ((\alpha_1, \ldots, \alpha_k), \sigma, (\beta_1, \ldots, \beta_k)) : \\
(\alpha_1, \ldots, \alpha_k) \mapsto (\beta_1, \ldots, \beta_k) \mid k \geq 1, \alpha_i \in S - \text{Mor}(C), \sigma : \{1, \ldots, k\} \to \{1, \ldots, n\} \text{ is a permutation, } \forall i, \beta_i = \alpha_{\sigma(i)}. \}
\]
(3.5)

For $f \in S \cup \{n\} - \text{Mor}(T_C)$ in (3.5), we sometimes denote the permutation $\sigma$ by $\sigma_f$. It suffices to have $\mathcal{B}_n$ as an $(n-1)$-fold category with an $(n-1)$-fold functor
\[
\mathcal{F}_n : \mathcal{B}_n \to T_{\mathcal{B}_{n-1}}.
\]
Then the $n$-fold category structure of $\mathcal{B}_n$ is induced by $\mathcal{F}_n$. Explicitly, for $S \subseteq \{1, \ldots, n-1\}$ and $x, y \in S - \text{Mor}(\mathcal{B}_n)$,

$$\text{(S \cup \{n\}) - \text{Mor}(\mathcal{B}_n)(x, y) = (S \cup \{n\}) - \text{Mor}(\mathcal{B}_{n-1})(\mathcal{F}(x), \mathcal{F}(y)).}$$

Then for $S \subseteq \{1, \ldots, n\}$ and $x \in S - \text{Mor}(\mathcal{B}_n)$, denote again the length of $\mathcal{F}_n(x) \,$ by $m_x$ and

$$\mathcal{F}_n(x) =: (f_1(x), \ldots, f_{m_x}(x)).$$

Thereby, $\mathcal{F}_n$ becomes an $n$-fold functor. We also have an $(n-1)$-fold functor $\mathcal{G}_n : \mathcal{B}_n \to \mathcal{B}_{n-1}$ given by applying the $\mathcal{B}_{n-1}$-composition, similar to that in our definition of $G_n$.

An example of a $\{1\}$-morphism in $\mathcal{B}_2$ is the map that takes the tree on the left to the tree on the right by

![Diagram](3.6)

Call it $\vartheta$. An example of a $\{2\}$-morphism in $\mathcal{B}_2$ is the map that takes the tree on the left to the tree on the right by

![Diagram](3.7)

Call it $\varrho$. Then we have a $\{1, 2\}$-morphism in $\mathcal{B}_2$ given by the following diagram:

![Diagram](Diagram)

where the maps on the left are $\varrho$, and the maps on the bottom are $\vartheta$. 
To capture the properties of the composition, define cube-like $n$-fold categories $\text{Comp}_n$ and $\text{Comp}_n^2$ as follows: for $S \subseteq \{1, \ldots, n-1\}$, define

$$S - \text{Mor}(\text{Comp}_n) = \{(x, i, y) \mid x, y \in S - \text{Mor}(\mathcal{B}_n), 1 \leq i \leq m_x, \mathcal{G}_n(y) = f_i(x)\} \quad (3.8)$$

$$(S \cup \{n\}) - \text{Mor}(\text{Comp}_n) = \{((x, i, y) \to (x, i', y), f,g) \mid 1 \leq i \leq m_x,$n

$$x, y \in S - \text{Mor}(\mathcal{B}_n), \mathcal{G}_n(y) = f_i(x), f : x \to x, g : y \to y, f, g \in (S \cup \{n\}) - \text{Mor}(\mathcal{B}_n), \ i' = \sigma_f(i)\}$$

$$(S \cup \{n\}) - \text{Mor}(\text{Comp}_n^2) = \{(x, i, j, y, z) \mid x, y, z \in S - \text{Mor}(\mathcal{B}_n), 1 \leq i \neq j \leq m_x,$n

$$x, y, z \in S - \text{Mor}(\mathcal{B}_n), \mathcal{G}_n(y) = f_i(x), \mathcal{G}_n(z) = f_j(x), f : x \to x, g : y \to y, h : z \to z, f, g, h \in S \cup \{n\} - \text{Mor}(\mathcal{B}_n), \ i' = \sigma_f(i), j' = \sigma_f(j)\}.$$n

Note that we then have, by definition, projection $n$-fold functors

$$\text{Comp}_n \to \mathcal{B}_n \times \mathcal{B}_n,$n

$$\text{Comp}_n^2 \to \mathcal{B}_n \times \mathcal{B}_n \times \mathcal{B}_n.$$n

We are also given (as a part of the induction data) increasing functions

$$\varphi_n^{(x,i,y)} : \{1, \ldots, m_x\} \to \{1, \ldots, m_x + m_y - 1\},$$

$$\psi_n^{(x,i,y)} : \{1, \ldots, m_x\} \to \{1, \ldots, m_x + m_y - 1\}$$

for $(x, i, y) \in S - \text{Mor}(\text{Comp}_n)$ for some $S \subseteq \{1, \ldots, n-1\}$, and a composition $n$-fold functor

$$\Phi_n : \text{Comp}_n \to \mathcal{B}_n.$$ (3.9)

Then define

$$\Phi_n^1, \Phi_n^2 : \text{Comp}_n^2 \to \text{Comp}_n$$

with

$$\Phi_n^1(x, i, j, y, z) = (\Phi_n(x, i, y), \varphi_n^{(x,i,y)}(j), z),$$

$$\Phi_n^2(x, i, j, y, z) = (\Phi_n(x, j, y), \psi_n^{(x,i,y)}(i), z).$$

On $(S \cup \{n\}) - \text{Mor}(\text{Comp}_n^2)$, $\Phi_n$, $\Phi_n^1$, and $\Phi_n^2$ are defined by the wreath products of the permutations such that

$$\text{Comp}_n^2 \xrightarrow{\Phi_n^1} \text{Comp}_n \xrightarrow{\Phi_n^2} \text{Comp}_n$$

$$\text{Comp}_n \xrightarrow{\Phi_n} \mathcal{B}_n$$ (3.10)

commutes strictly. (Note that then the $\{n\}$-morphisms of $\mathcal{B}_n$ are permutations.)

We construct the $\mathcal{B}_n$'s inductively. Suppose that we are given $\mathcal{B}_n$ and all of the associated maps. Then take a cube-like $n$-fold category $\mathcal{C}$ with a fibered $n$-fold functor

$$\mathcal{C} \to \mathcal{B}_n.$$n

For $S \subseteq \{1, \ldots, n\}$, denote the preimage of an $S$-morphism $x$ by $\mathcal{C}(x)$. Then let

$$\text{Comp}_{\mathcal{C}} = (\mathcal{C} \times \mathcal{C}) \times (\mathcal{B}_n \times \mathcal{B}_n) \text{ Comp}_n,$$n

$$\text{Comp}_{\mathcal{C}}^2 = (\mathcal{C} \times \mathcal{C} \times \mathcal{C}) \times (\mathcal{B}_n \times \mathcal{B}_n \times \mathcal{B}_n) \text{ Comp}_n.$$
Definition 3.4. A cube-like $n$-fold category $\mathcal{C}$ with a fibered $n$-fold functor $\mathcal{C} \to \mathcal{B}_n$ is called an $n$-actad provided that there exist $n$-fold functors
\[ \Gamma : \text{Comp}_\mathcal{C} \to \mathcal{C}, \]
\[ \Gamma^1, \Gamma^2 : \text{Comp}_\mathcal{C}^2 \to \text{Comp}_\mathcal{C} \]
such that the following axioms hold:

1. \[ \Gamma^1 = (\Gamma \times \text{Id}_\mathcal{C}) \times \text{Comp}_\mathcal{B}_n \Phi^1. \]

2. \[ \Gamma^2 = (\text{Id}_\mathcal{C} \times \Gamma) \times \text{Comp}_\mathcal{B}_n \Phi^2. \]

3. \[ \text{Comp}_\mathcal{C}^2 \Gamma^1 \to \text{Comp}_\mathcal{C} \Gamma^2 \]

strictly commutes.

Let $\mathcal{C}_n$ be the category of $n$-actads, and let $\mathcal{D}_n$ be the category of $n$-fold fibered categories over $\mathcal{B}_n$. Then we have a forgetful fibered functor
\[ \mathcal{C}_n \to \mathcal{D}_n. \]
Then the left adjoint to this functor is called a free $n$-actad.

Suppose that we are given $\mathcal{B}_n$, the $n$-actads and all of the associated maps. Suppose that $\mathcal{C}$ is an $n$-fold category and $S \subseteq \{1, \ldots, n\}$. Recall that for $I : S \to \{0, 1\}$, we have the source-target map (3.2).

We then define the $(n + 1)$-base $\mathcal{B}_{n+1}$ as a cube-like $n$-fold category by letting, for $S \subseteq \{1, \ldots, n\}$, $S - \text{Mor}(\mathcal{B}_{n+1})$ be the free plain $n$-actad on $\text{Mor}(\mathcal{B}_{n+1}) \to \mathcal{B}_n$.

It is tempting to conclude that $\mathcal{B}_{n+1}$ is the free $n$-actad on $\mathcal{B}_n$, but that is false because for $S \subseteq \{1, \ldots, n\}$, not all $S$-morphisms of $\mathcal{B}_n$ can be lifted to $\mathcal{B}_{n+1}$ via $\mathcal{B}_n$. This is due to the fact that an additional structure is being introduced, where not all the isomorphisms downstairs will preserve it: for example, for $n = 2$, not every 1-permutation of the prongs of a planar tree comes from an actual isomorphism of trees. Thus, $\mathcal{B}_{n+1}$ is, in fact, not a fibered $n$-fold category over $\mathcal{B}_n$ (via $\mathcal{B}_n$), and consequently not an $n$-actad. On the other hand, $\mathcal{B}_{n+1} : \mathcal{B}_n \to \mathcal{B}_n$ satisfies the uniqueness axiom of a fibered $n$-fold category, and in fact, the following is true (see also Section 8 below).

Lemma 3.5. Let $\mathcal{V}$ be the forgetful functor from the category of fibered $n$-fold categories over $\mathcal{B}_n$ to the category of $n$-fold categories over $\mathcal{B}_n$ (and $n$-fold functors). Let $\mathcal{V}$ be the left adjoint to $\mathcal{V}$ ("left Kan extension"). Then $\mathcal{B}_{n+1} = \mathcal{V} \mathcal{B}_{n+1}$ is the free $n$-actad on $\mathcal{B}_n$ on $\text{Id} : \mathcal{B}_n \to \mathcal{B}_n$.

(Note that in the case of $n = 1$, 1-actads are simply operads.)
4 Algebras over an \( n \)-actad

The next thing we will discuss is algebras over an \( n \)-actad \( \mathcal{C} \). For operads, which are 1-actads, an algebra over an operad \( \mathcal{C} \) is an \( X \) with
\[
\mathcal{C}(n) \times X^n \to X
\]
satisfying the appropriate axioms (associativity, and, if we choose, commutativity in the broader sense and unitality), and a module over an operad \( \mathcal{C} \) and an algebra \( X \) is a \( Y \) with
\[
\mathcal{C}(n) \times X^{n-1} \times Y \to Y
\]
satisfying similar axioms.

Now, take an \( (n-1) \)-fold category \( X \). Suppose that we also have a fibered \( (n-1) \)-fold functor \( \Xi: X \to \mathcal{B}_{n-1} \) (then, in particular, \( X \) is cube-like). For \( S \subseteq \{1, \ldots, n-1\} \) and \( a \in S - \text{Mor}(\mathcal{B}_{n-1}) \), let the inverse image of \( \Xi \) of \( a \) again be called \( X(a) \).

Suppose that we have \( S \subseteq \{1, \ldots, n-1\} \). Then define the extra structure for \( X \) needed to be an \( n \)-fold category, by insisting that the map
\[
(S \cup \{n\} - \text{Mor}(X)) \xrightarrow{\text{Id}} (S - \text{Mor}(X))
\]
(4.1) be a bijection.

Let \( \mathcal{C} \) be an \( n \)-actad. Then by definition, we have an \( n \)-fold functor
\[
\mathcal{C} \rightarrow \mathcal{B}_n \xrightarrow{\mathcal{F}_n} T_{\mathcal{B}_{n-1}}.
\]

Also, we have
\[
T_\Xi: T_X \rightarrow T_{\mathcal{B}_{n-1}}.
\]

So we can form the pullback \( \mathcal{C} \times_{\mathcal{B}_{n-1}} T_X \).

**Definition 4.1.** \( X \) is called an algebra over \( \mathcal{C} \) provided that the following holds: there exists an \( (n-1) \)-fold functor
\[
\Theta: \mathcal{C} \times_{\mathcal{B}_{n-1}} T_X \rightarrow X
\]
(4.2) such that the diagram
\[
\begin{array}{ccc}
\mathcal{C} \times_{\mathcal{B}_{n-1}} T_X & \xrightarrow{\Theta} & X \\
\pi \downarrow & & \downarrow \Xi \\
\mathcal{C} & \xrightarrow{\mathcal{F}_n} & \mathcal{B}_n \xrightarrow{T_\Xi} \mathcal{B}_{n-1}
\end{array}
\]

commutes, where \( \pi \) is the projection, and the map \( \mathcal{C} \rightarrow \mathcal{B}_n \) is the fibered \( n \)-functor given by definition. Note that though some of the functors in this diagram are \( n \)-fold functors, this diagram is of \( (n-1) \)-fold functors. We require the following conditions to hold:

1. **Equivariance.** By the above comment on the \( n \)-fold categorical structure of \( X \), we have that \( \mathcal{C} \times_{\mathcal{B}_{n-1}} T_X \) is already an \( n \)-fold category. Then we require (4.2) to be an \( n \)-fold functor.

2. **Associativity.** First, fix \( x, y \in S - \text{Mor}(\mathcal{B}_n), S \subseteq \{1, \ldots, n-1\} \) and \( i \in \{1, \ldots, m_x\} \) with \( f_i(x) = \mathcal{G}_n(y) \). Or, in other words, \( (x, i, y) \in \text{Comp}_n \). Then write \( x_j = f_j(x) \) and \( y_k = f_k(y) \).
Suppose that we have\[\xi \in \mathcal{C}(x) \times \mathcal{C}(y) \times \{(x,i,y)\}\].

Recall that elements of \(\mathcal{C}(x)\) are \(S\)-morphisms of \(\mathcal{B}_n\) over \(x\). Then define \(\Omega(\xi) = (z_1, \ldots, z_{m_x+m_y-1})\) by \(z_{\varphi_n(x,i,y)}(j) = x_j\) and \(z_{\psi_n(x,i,y)}(k) = y_k\). Then
\[
\Omega : \mathcal{C}(x) \times \mathcal{C}(y) \times \{(x,i,y)\} \to T_{\mathcal{B}_n-1}.
\]

We also have \(T_{\Xi} : T_X \to T_{\mathcal{B}_n-1}\). So we can write \((\mathcal{C}(x) \times \mathcal{C}(y) \times \{(x,i,y)\}) \times T_{\mathcal{B}_n-1} T_X\)

Then define
\[
\tilde{\Theta}_{(x,i,y)} : (\mathcal{C}(x) \times \mathcal{C}(y) \times \{(x,i,y)\}) \times T_{\mathcal{B}_n-1} T_X \to \mathcal{C}(x) \times T_{\mathcal{B}_n-1} \prod_{1 \leq j \leq m_x} X(x_j)
\]

by
\[
\tilde{\Theta}_{(x,i,y)} = (\varpi, \text{Id}_{\mathcal{C}(x) \times \prod_{1 \leq j \leq m_x} x(x_j)} \times \Theta |_{\mathcal{C}(y) \times T_{\mathcal{B}_n-1} \prod_{1 \leq k \leq m_y} y(y_k)}),
\]

where, again,
\[
\varpi : (\mathcal{C}(x) \times \mathcal{C}(y) \times \{(x,i,y)\}) \times T_{\mathcal{B}_n-1} T_X \to \mathcal{C}(x)
\]
is the projection to the first coordinate.

Now, let
\[
\tilde{\Theta} = \prod_{(x,i,y) \in \text{Comp}_n} \tilde{\Theta}_{(x,i,y)}.
\]

Then, since
\[
\text{Comp}_n = (\mathcal{C} \times \mathcal{C}) \times (\mathcal{B}_n \times \mathcal{B}_n) \text{ Comp}_n,
\]
we have
\[
\tilde{\Theta} : \text{Comp}_n \times T_{\mathcal{B}_n-1} T_X \to \mathcal{C} \times T_{\mathcal{B}_n-1} T_X.
\]

Then
\[
\text{Comp}_n \times T_{\mathcal{B}_n-1} T_X \xrightarrow{\Gamma \times \text{Id}} \mathcal{C} \times T_{\mathcal{B}_n-1} T_X
\]

must strictly commute. Actually, \(\tilde{\Theta}\) can be extended uniquely and naturally to \(S \cup \{n\}\)-morphisms, and (4.4) is automatically a diagram of \(n\)-fold functors.

Again, at \(n = 1\), this simply corresponds to the concept of algebras over an operad.

**Example 4.2.** Let \(\mathcal{A}_n\) be the \(n\)-actad given by taking, for \(S \subseteq \{1, \ldots, n-1\}\),
\[
S - \text{Mor}(\mathcal{A}_n) = (S \cup \{n\}) - \text{Mor}(\mathcal{B}_n),
\]
and \((S \cup \{n\}) - \text{Mor}(\mathcal{A}_n)\) consists of the \(n\)-composable pairs of \((S \cup \{n\}) - \text{Mor}(\mathcal{B}_n)\), i.e., the pairs
\[
(\sigma, \tau) \in ((S \cup \{n\}) - \text{Mor}(\mathcal{B}_n))^2
\]
such that \(S_n \tau = T_n \sigma \in S - \text{Mor}(\mathcal{B}_n)\), where \(S_n\) and \(T_n\) denote the \(n\)-source and the \(n\)-target of an \(S \cup \{n\}\)-morphism, respectively. Then there is an equivalence of categories between \(\mathcal{A}_n\)-algebras and \((n-1)\)-actads. More specific examples of \(\mathcal{A}_n\)-algebras will be given in later sections.

**Example 4.3.** Note that, of course, \(\mathcal{B}_n\) is an \(n\)-actad via \(\text{Id} : \mathcal{B}_n \to \mathcal{B}_n\). We call \(\mathcal{B}_n\)-algebras \(n\)-commutative \((n-1)\)-actads (in the narrower sense).
5 Modules of algebras over n-actads

Suppose that $X$ and $M$ are $(n-1)$-fold categories and we have fibered $(n-1)$-fold functors $\Xi_X : X \to \mathcal{B}_{n-1}$ and $\Xi_M : M \to \mathcal{B}_{n-1}$. Then let, again, $X(x)$ and $M(x)$ denote the inverse images under $\Xi_X$ and $\Xi_M$ of $x \in \mathcal{B}_{n-1}$, respectively. For $S \subseteq \{1, \ldots, n-1\}$, define $T_{X,M}$ by

\[
S - \text{Mor}(T_{X,M}) = \{( (t,k),(x_1,\ldots,x_{i-1},m,x_{i+1},\ldots,x_k) ) \mid 1 \leq t \leq k \in \mathbb{N}, x_j \in S - \text{Mor}(X), m \in S - \text{Mor}(M) \},
\]

\[
(S \cup \{n\}) - \text{Mor}(T_{X,M}) = \{ ( (\sigma, t,k),(x_1,\ldots,x_{i-1},m,x_{i+1},\ldots,x_k) ) \mid 1 \leq t \leq k \in \mathbb{N}, x_j \in S - \text{Mor}(X), m \in S - \text{Mor}(M), \sigma \in \Sigma_k \}.
\]

For an $\eta = ((t,k),(x_1,\ldots,x_{i-1},m,x_{i+1},\ldots,x_k)) \in S - \text{Mor}(T_{X,M})$, write $t_0 = t$.

**Definition 5.1.** Suppose that $\mathcal{C}$ is an $n$-actad and $X$ is a $\mathcal{C}$-algebra. Then $M$ is a $(\mathcal{C},X)$-module provided that the following holds: there exists an $(n-1)$-fold functor

\[
\Theta : \mathcal{C} \times T_{\mathcal{B}_{n-1}} T_{X,M} \to M
\]

such that

\[
\begin{array}{ccc}
\mathcal{C} \times T_{\mathcal{B}_{n-1}} T_{X,M} & \xrightarrow{\Theta} & M \\
\downarrow \pi & & \downarrow \Xi_M \\
\mathcal{C} & \xrightarrow{\mathcal{C}} & \mathcal{B}_{n-1}
\end{array}
\]

where $\pi$ is the projection, and the map $\mathcal{C} \to \mathcal{B}_n$ is the $n$-functor given by the definition. Note that though some of the functors in this diagram are $n$-fold functors, this diagram is of $(n-1)$-fold functors. We also require the following conditions to hold:

(1) **Equivariance.** Suppose that we have $S \subseteq \{1, \ldots, n-1\}$. Then define the extra structure for $M$ needed to be an $n$-fold category, by insisting that the map

\[
(S \cup \{n\}) - \text{Mor}(M) \xrightarrow{\text{id}} (S - \text{Mor}(M))
\]

be an isomorphism. With this extra structure, $M$ is an $n$-fold category. We have that $\mathcal{C} \times T_{\mathcal{B}_{n-1}} T_{X,M}$ is already an $n$-fold category. Then (5.2) must be an $n$-fold functor.

(2) **Associativity.** We will use the symbols $x, y, S, i, x_j, y_k$ and $\Omega$ in the same way as in Axiom (2) in Section 4. We have

\[
T_{\Xi_X} : T_X \to T_{\mathcal{B}_{n-1}}.
\]

We define

\[
\Upsilon : T_{X,M} \to T_{\mathcal{B}_{n-1}}
\]

by

\[
\Upsilon(x_1,\ldots,x_{i-1},m,x_{i+1},\ldots,x_k) = (\Xi_X(x_1),\ldots,\Xi_X(x_{i-1}),\Xi_M(m),\Xi_X(x_{i+1}),\ldots,\Xi_X(x_k)).
\]

So we can write

\[
(\mathcal{C}(x) \times \mathcal{C}(y) \times \{(x,i,y)\}) \times T_{\mathcal{B}_{n-1}} T_{X,M}.
\]

Then define

\[
\Theta_{(x,y)} : (\mathcal{C}(x) \times \mathcal{C}(y) \times \{(x,i,y)\}) \times T_{\mathcal{B}_{n-1}} T_{X,M} \to \mathcal{C}(x) \times T_{\mathcal{B}_{n-1}} \bigotimes_{1 \leq j \leq m_x} M(x_j)
\]
by

\[ \tilde{\Theta}_{(x,y)} = (\pi, \text{Id}_{\mathcal{C}(x)} \times \prod_{j \in m(y)} X M_j (x_i) \times \Theta | \mathcal{C}(y) \times \prod_{k \in m(y)} X M_k (y_k)), \]

where, for \( \eta \in T_{X,M} \) on \( \mathcal{C}(x) \times \mathcal{C}(y) \times \{(x,i,y)\} \times T_{\mathcal{B}^{n-1}} \{\eta\}, \)

\[ XM_j = X \quad \text{for } j \neq i, \]
\[ XM_j = M \quad \text{for } j = i. \]

Then

\[ \text{Comp}_{\mathcal{C}} \times T_{\mathcal{B}^{n-1}} T_{X,M} \xrightarrow{\Gamma \times \text{Id}} \mathcal{C} \times T_{\mathcal{B}^{n-1}} T_{X,M} \]

must strictly commute.

We can also define a concept of a \((\mathcal{C}, X)\)-algebra \( M \) analogously by modifying the definition so as to allow multiple \( m_j \)'s in (5.1).

6 Iterated algebras

There is a concept of an \( I \)-iterated algebra over an \( n \)-actad for any subset \( I \in \{0, \ldots, n\} \), of which the concepts of algebra and algebra with a module introduced in the last two sections are special cases for \( I = \{n\} \) and \( I = \{0, n\} \), respectively. We will use these constructions later to define unital actads and \( R \)-units. An \( I \)-iterated algebra consists of \(|I|\)-cube-like \((n-1)\)-fold categories, with rules about where they can be “plugged into an element of a given \( n \)-actad”. The ways of plugging in the \( \alpha \)-th model, for an \( \alpha \in I \), follow, roughly, the pattern of the definition of an \( \alpha \)-actad algebra. However, the precise axiomatization is delicate, in particular, on morphisms. The only axiomatization I could work out uses multisorted algebras [6]. One must also design an appropriate multisorted version of the \( n \)-base, to keep track of the structure describing how the different models are being plugged in.

In the below picture, I illustrate how the 0-, 1-, and 2-models are plugged in for the composition for the 0-, 1-, and 2-models of a \( \{0, 1, 2\} \)-iterated algebra over a 2-actad (the solid nodes mark the places where trees that will be labeled a number \( \geq 0 \) are composed).

We shall start with the concept of the \( I \)-pointed \( n \)-base \( \mathcal{R}^I_n \), a cube-like \( n \)-fold category, which will be defined inductively.
We start the induction with $B_0^{[0]} = B_0 = B_0$. For $k \geq 0$, $0 \leq \alpha_1 < \cdots < \alpha_k \leq n$ and $I = \{\alpha_1, \ldots, \alpha_k\}$, $B_n^{I} = B_n^{\alpha_1, \ldots, \alpha_k}$ is an $n$-fold category with an $n$-fold functor

$$B_n^{\alpha_1, \ldots, \alpha_k} \to B_n$$

and with some additional maps. First, $B_n^{\alpha_1, \ldots, \alpha_k}$ comes with additional data of the $n$-fold functor

$$\varphi_n : B_n^{\alpha_1, \ldots, \alpha_k} \to \{1, \ldots, k\}$$

as part of the induction data, where on the right-hand side, all the morphisms are identities. We shall also write

$$B_n^I(i) = B_n^{\alpha_1, \ldots, \alpha_k}(i) = \varphi_n^{-1}(i).$$

We will construct $B_n^{\alpha_1, \ldots, \alpha_k}$ (and the associated structure) inductively on $n$. The induction step from $(n-1)$ to $n$ depends in a crucial way on whether $\alpha_k < n$ or $\alpha_k = n$. Essentially, if $\alpha_k < n$, the induction step from $B_{n-1}^{\alpha_1, \ldots, \alpha_k}$ is similar to that for $B_n$. If $\alpha_k = n$, the induction step to $B_n^{\alpha_1, \ldots, \alpha_k}$ will be from $B_{n-1}^{\alpha_1, \ldots, \alpha_k}$ to $B_n^{\alpha_1, \ldots, \alpha_k}$. The rules for plugging in the new model are essentially to plug into one of the places of the previous one, but the $(S \cup \{n\})$-morphisms must remember their positions.

In more detail, if $\alpha_k < n$, then we have an $(n-1)$-fold functor over $\{1, \ldots, k\}$:

$$F_n^{\alpha_1, \ldots, \alpha_k} : B_n^{\alpha_1, \ldots, \alpha_k} \to T_{B_{n-1}^{\alpha_1, \ldots, \alpha_k}}$$

where in the vertical arrow, an $S$-morphism $(x_1, \ldots, x_n)$ with $S \subseteq \{1, \ldots, n-1\}$ is mapped to

$$\max_{i \in \{1, \ldots, m\}} \varphi_{n-1}(x_i).$$

(6.2)

Then, like in the case of $n$-bases, $F_n^{\alpha_1, \ldots, \alpha_k}$ induces an $n$-fold category structure on $B_n^{\alpha_1, \ldots, \alpha_k}$, and thus becomes an $n$-fold functor. Again, we will also have an $(n-1)$-fold functor

$$\vartheta_n : B_n^{\alpha_1, \ldots, \alpha_k} \to B_{n-1}^{\alpha_1, \ldots, \alpha_k}$$

as part of the induction data.

Definitions of $\text{Comp}_{n}^{\alpha_1, \ldots, \alpha_k}$ and $\text{Comp}_{n}^{2,\alpha_1, \ldots, \alpha_k}$ then proceed precisely analogously to the definitions of $\text{Comp}_n$ and $\text{Comp}_n^2$ in Section 3, except for the fact that we are working over $\{1, \ldots, k\}$. The analogue of the diagram (3.10) becomes a diagram of the form

$$\begin{array}{ccc}
\text{Comp}_n^{2,\alpha_1, \ldots, \alpha_k} & & \text{Comp}_n^{\alpha_1, \ldots, \alpha_k} \\
\phi_n^{2,\alpha_1, \ldots, \alpha_k} & & \phi_n^{1,\alpha_1, \ldots, \alpha_k} \\
\text{Comp}_n^{\alpha_1, \ldots, \alpha_k} & & \text{Comp}_n^{\alpha_1, \ldots, \alpha_k}
\end{array}$$

(6.3)

over $\{1, \ldots, k\}$.

Now, suppose $\alpha_k = n$. This case must be treated in more detail. Define a map

$$\varpi : \{1, \ldots, k\} \to \{1, \ldots, k-1\}$$

by

$$\varpi(i) = i \quad \text{for } i < k,$$

$$\varpi(k) = k - 1.$$
**Definition 6.1.** Suppose that \( \mathcal{C} \to \{1, \ldots, k - 1\} \) is an \((n - 1)\)-fold category over \( \{1, \ldots, k - 1\}\). Then define an \(n\)-fold category \( T^*_\mathcal{C} \to \{1, \ldots, k\} \) over \( \{1, \ldots, k\} \) as follows: for \( i \in \{1, \ldots, k - 1\} \),

\[
T^*_\mathcal{C}(i) = T_{\mathcal{C}(i)}.
\]

For \( S \subseteq \{1, \ldots, n - 1\} \),

\[
S - \text{Mor}(T^*_\mathcal{C}(k)) = \{((x_1, \ldots, x_\ell), b) \mid \ell \geq 1, b \in \{1, \ldots, \ell\}, \forall j, \exists i_j \in \{1, \ldots, k - 1\} \text{ such that } x_j \in S - \text{Mor}(\mathcal{C}(i_j)), i_b = k - 1\}
\]

and

\[
(S \cup \{n\}) - \text{Mor}(T^*_\mathcal{C}(k)) = \{f = (((x_1, \ldots, x_\ell), b), \sigma, (y_1, \ldots, y_\ell)) : \quad \\
((x_1, \ldots, x_\ell), b) \to ((y_1, \ldots, y_\ell), \sigma(b)) \mid \ell \geq 1, \\
b \in \{1, \ldots, \ell\}, \sigma : \{1, \ldots, \ell\} \to \{1, \ldots, \ell\} \text{ is a permutation}, \\
\sigma(b) = b, \forall i, y_i = x_{\sigma(i)}\}.
\]

We have an obvious forgetful \(n\)-fold functor

\[
\begin{array}{ccc}
T^*_\mathcal{C} & \rightarrow & T_{\mathcal{C}} \\
\downarrow & & \downarrow \\
\{1, \ldots, k\} & \xrightarrow{\mathcal{F}_n} & \{1, \ldots, k - 1\}
\end{array}
\]

forgetting \( b \).

Then we are also given an \((n - 1)\)-fold functor

\[
\mathcal{F}_n^I : \mathcal{B}_n^I = \mathcal{B}_n^\alpha_1 \cdots \alpha_k \to T^*_\mathcal{B}_n^{\alpha_1 \cdots \alpha_k - 1}
\]

(6.4)

as part of the induction data. Like in the previous cases, \( \mathcal{F}_n^I \) becomes an \(n\)-fold functor. In addition, like in the previous cases, we have an \((n - 1)\)-fold functor

\[
\mathcal{G}_n^I : \mathcal{B}_n^I \to \mathcal{B}_n^{\alpha_1 \cdots \alpha_k - 1}
\]

with the following diagram:

\[
\begin{array}{ccc}
\mathcal{B}_n^I & \rightarrow & \mathcal{B}_n^{\alpha_1 \cdots \alpha_k - 1} \\
\downarrow & & \downarrow \\
\{1, \ldots, k\} & \xrightarrow{\mathcal{F}_n^I} & \{1, \ldots, k - 1\}. 
\end{array}
\]

Then for \( S \subseteq \{1, \ldots, n - 1\} \) and \( x \in S - \text{Mor}(\mathcal{B}_n^I) \), let

\[
\mathcal{F}_n^I(x) = : (f_1(x), \ldots, f_m(x)).
\]

Now, we use these functors to define the \(n\)-fold categories \(\text{Comp}^{\alpha_1 \cdots \alpha_k}_n\) and \(\text{Comp}^{\alpha_1 \cdots \alpha_k}_n\), similar to the case of \(n\)-bases: for \( S \subseteq \{1, \ldots, n - 1\} \), define

\[
S - \text{Mor}(\text{Comp}^{\alpha_1 \cdots \alpha_k}_n) = \{(x, i, y) \mid x, y \in S - \text{Mor}(\mathcal{B}_n^{\alpha_1 \cdots \alpha_k}), 1 \leq i \leq m_x, \mathcal{B}_n(y) = f_i(x)\},
\]

\[
(S \cup \{n\}) - \text{Mor}(\text{Comp}^{\alpha_1 \cdots \alpha_k}_n) = \{((x, i, y) \to (x, i', y), f, g) \mid 1 \leq i \leq m_x, \\
x, y \in S - \text{Mor}(\mathcal{B}_n^{\alpha_1 \cdots \alpha_k}), \mathcal{B}_n(y) = f_i(x), \\
f : x \to x, g : y \to y, f, g \in (S \cup \{n\}) - \text{Mor}(\mathcal{B}_n), i' = \sigma_f(i)\}.
\]
$S = \text{Mor}(\text{Comp}_n^{2;\alpha_1,\ldots,\alpha_k}) = \{(x, i, j, y, z) \mid x, y, z \in S - \text{Mor}(\mathcal{B}_n^{1;\ldots,\alpha_k})\},$

$1 \leq i \neq j \leq m_x, \mathcal{F}_n(y) = f_i(x), \mathcal{G}_n(z) = f_j(x),$

$(S \cup \{n\}) - \text{Mor}(\text{Comp}_n^{2;\alpha_1,\ldots,\alpha_k}) = \{((x, i, j, y, z) \rightarrow (x, i', j', y, z), f, g, h) \mid 1 \leq i \neq j \leq m_x,$

$x, y, z \in S - \text{Mor}(\mathcal{B}_n^{1;\ldots,\alpha_k}), \mathcal{F}_n(y) = f_i(x), \mathcal{G}_n(z) = f_j(x),$

$f : x \rightarrow x, g : y \rightarrow y, h : z \rightarrow z, f, g, h \in S \cup \{n\} - \text{Mor}(\mathcal{B}_n), i' = \sigma_f(i), j' = \sigma_f(j)\}.$

Then define maps

$\Pi_1 : \text{Comp}_n^{\alpha_1,\ldots,\alpha_k} \rightarrow \{1, \ldots, k\},$

$\Pi_2 : \text{Comp}_n^{2;\alpha_1,\ldots,\alpha_k} \rightarrow \{1, \ldots, k\}$

by

$\Pi_1(x, i, y) = \varpi(x),$

$\Pi_2(x, i, j, y, z) = \varpi(x).$

Also, like before, we have

$\text{Comp}_n^{\alpha_1,\ldots,\alpha_k} \rightarrow \mathcal{B}_n^{1;\ldots,\alpha_k} \times \mathcal{B}_n^{1;\ldots,\alpha_k},$

$\text{Comp}_n^{2;\alpha_1,\ldots,\alpha_k} \rightarrow \mathcal{B}_n^{1;\ldots,\alpha_k} \times \mathcal{B}_n^{1;\ldots,\alpha_k} \times \mathcal{B}_n^{1;\ldots,\alpha_k},$

$\mathcal{F}_n^{(x, i, y)} : \{1, \ldots, m_x\} \rightarrow \{1, \ldots, m_y + m_y - 1\},$

$\Phi_n : \text{Comp}_n^{\alpha_1,\ldots,\alpha_k} \rightarrow \mathcal{B}_n^{1;\ldots,\alpha_k}$

and

$\Phi_n^1, \Phi_n^2 : \text{Comp}_n^{2;\alpha_1,\ldots,\alpha_k} \rightarrow \text{Comp}_n^{\alpha_1,\ldots,\alpha_k},$

where the diagram analogous to (6.3) commutes.

Then suppose that we are given $\mathcal{B}_n^{1;\ldots,\alpha_k}$ and all of their associated structure described above.

To construct, for $\{\alpha_1, \ldots, \alpha_k\} \subseteq \{0, \ldots, n\}$, $\mathcal{B}_n^{1;\ldots,\alpha_k}$ from $\mathcal{B}_n^{1;\ldots,\alpha_k}$, we can proceed precisely analogously to the end of Section 3: for $S \subseteq \{1, \ldots, n\}$, $S - \text{Mor}(\mathcal{B}_n^{0;\ldots,\alpha_k})$ is the $(n + 1)$-dimensional free plain actad sorted over $\{1, \ldots, k\}$ (i.e., the plain actad in the category of sets over $\{1, \ldots, k\}$) on

$\mathcal{F}_n : S - \text{Mor}(\mathcal{B}_n^{1;\ldots,\alpha_k}) \rightarrow B_n \times \{1, \ldots, k\}.$

Again, this is an invertible cube-like category and $0$ could be equivalently replaced by any $I : S \rightarrow \{0, 1\}$. We let

$\mathcal{F}_n^{1;\ldots,\alpha_k, n + 1} = \mathcal{B}_n^{1;\ldots,\alpha_k} \times \mathcal{B}_n \times \mathcal{B}_n^{1;\ldots,\alpha_k} \times \mathcal{F}_n^{1;\ldots,\alpha_k}.$

(In particular, by definition, $\mathcal{B}_n^0 = \mathcal{B}_n$ for all $n$.)

Now, we define iterated algebras. Let $\mathcal{C}$ be an $n$-actad. Let $0 \leq \alpha_1 < \cdots < \alpha_k \leq n$. Let

$\mathcal{C}^{\alpha_1,\ldots,\alpha_k} = \mathcal{C} \times \mathcal{B}_n \mathcal{B}_n^{1;\ldots,\alpha_k},$

$\text{Comp}_n^{\alpha_1,\ldots,\alpha_k} = (\mathcal{C} \times \mathcal{C}) \times (\mathcal{B}_n \times \mathcal{B}_n) \text{Comp}_n^{\alpha_1,\ldots,\alpha_k}.$

(Note that we have a forgetful $n$-fold functor $\mathcal{B}_n^{1;\ldots,\alpha_k} \rightarrow \mathcal{B}_n$.)

Definition 6.2. Suppose that $\mathcal{D}$ is an $(n - 1)$-fold category over $\mathcal{B}_n^{-1} \times \{1, \ldots, k\}$. Then for $i = 1, \ldots, k$, let $\mathcal{D}(i)$ be the sub-$(n - 1)$-fold categories that are fibered over $\mathcal{B}_n^{-1} \times \{i\}$. Then let $T^{k}_{\mathcal{D}}$ be the $n$-fold category with

$S - \text{Mor}(T^{k}_{\mathcal{D}}) = \{(x_1, \ldots, x_k) \mid \forall j, \exists i_j \in \{1, \ldots, k - 1\} \text{ such that } x_j \in S - \text{Mor}(\mathcal{D}(i_j))\},$
A unit axiom can be added to the concept of an \( R \)-actad where

\[
\forall j, x_j \in S - \text{Mor}(\mathcal{P}(i_j)), y_j \in S - \text{Mor}(\mathcal{P}(\sigma(i_j))) \text{ and } y_j = x_{\sigma(i_j)}
\]

for \( S \subseteq \{1, \ldots, k-1\} \).

An iterated \((\alpha_1, \ldots, \alpha_k) - \mathcal{C}\) algebra is a \( k \)-tuple of fibered \((n-1)\)-fold categories \( X = (X_1, \ldots, X_k) \) over \( \mathcal{R}_{n-1} \) together with an \((n-1)\)-fold functor

\[
\Theta : \mathcal{C}^{\alpha_1, \ldots, \alpha_k} \times T^k_{\mathcal{R}_{n-1} \times \{1, \ldots, k\}} \rightarrow X
\]

with

\[
\mathcal{C}^{\alpha_1, \ldots, \alpha_k} \times T^k_{\mathcal{R}_{n-1} \times \{1, \ldots, k\}} \xrightarrow{\Theta} X
\]

Again, there are equivariance and associativity axioms. Equivariance, again, says that \( \Theta \) is an \( n \)-fold functor if we let (4.1) be a bijection. Associativity is expressed by the commutativity of a diagram of \( n \)-fold:

\[
\begin{array}{ccc}
\text{Comp}^{\alpha_1, \ldots, \alpha_k} \times T^k_{\mathcal{R}_{n-1} \times \{1, \ldots, k\}} & \xrightarrow{\Gamma \times Id} & \mathcal{C}^{\alpha_1, \ldots, \alpha_k} \times T^k_{\mathcal{R}_{n-1} \times \{1, \ldots, k\}} \\
\tilde{\Theta} & \downarrow & \Theta \\
T^k_{\mathcal{R}_{n-1} \times \{1, \ldots, k\}} & \xrightarrow{\Theta} & X,
\end{array}
\]

where \( \tilde{\Theta} \) is defined analogously to (4.3).

As an example, note that the cases of \( \mathcal{R}_n^{(n)} \) and \( \mathcal{R}_n^{(0,n)} \) give the notions of algebras and modules, respectively, over \( n \)-actads.

\section{R-unital actads and bases}

A unit axiom can be added to the concept of an \( n \)-actad (or a plain \( n \)-actad) without difficulty. Perhaps the most surprising aspect of units is how diverse they become for \( n > 1 \): in the plain case, the unit is expressed by the natural inclusion

\[
B_{n-1} \subseteq B_n, \quad n \geq 1,
\]

given by the fact that \( B_n \) is the free plain \((n-1)\)-actad on \( \text{Id} : B_{n-1} \rightarrow B_{n-1} \).

We introduce the notation \( 1^n_x \in B_n \) for the image of every \( y \in B_{n-1} \). Then \( \forall x = (x_1, \ldots, x_n), (i_1, \ldots, i_{n-1}) \),

\begin{enumerate}
\item \( x \circ^n_{i_1} 1^n_{i_k} = x \); \\
\item \( \forall y \in B_n \) such that \( G_n(y) = x \), \( 1^n_x \circ^n_1 y = y \).
\end{enumerate}

Then, we can define a unital plain actad as follows.

\textbf{Definition 7.1.} Suppose we are given a plain \( n \)-actad \( \mathcal{C} \). Then \( \mathcal{C} \) is a unital plain actad provided that for \( x \in B_{n-1}, y \in B_n \) and \( z \in \mathcal{C}(y) \), we are given an element \( 1_{n,z} \in \mathcal{C}(1^n_x) \) such that

\begin{enumerate}
\item \( \gamma_{n,j}(z, 1_{n,z}) = z \); \\
\item \( \gamma_{n,j}(1_{n,z}, z) = z \) if \( G_n(y) = x \).
\end{enumerate}

For \( n = 0 \), there is also a unit \( 1_{0,z} \), even though there is no \(-1\) base.
A unital 0-actad is a monoid (instead of just a semigroup). For actads, the story is analogous. Here, only the case of $n > 0$ is new. By the definition of $B_{n+1}$ from $B_n$ at the end of Section 3, we also obtain a canonical inclusion $(n-1)$-fold functor of $(n-1)$-fold categories

$$\mathcal{I}_n : B_{n-1} \to B_n.$$  \hspace{1cm} (7.2)

In fact, it becomes an $n$-fold functor if we define all the $\{n\}$-morphisms to be identities in the source. In fact, (7.2) is a section of the $(n-1)$-fold functor $\mathcal{I}_n$. (In particular, in the $n$-actad case, note that units have $\{i\}$-automorphisms for $i < n$.)

The left unit property for $B_n$ then can be expressed by introducing a left unit functor

$$\mathcal{H}_n : B_n \to \text{Comp}_n$$

by

$$x \mapsto (\mathcal{I}_n x, 1, x)$$

(see (3.8)). Then the diagram

$$\begin{array}{ccc}
B_n & \xrightarrow{\mathcal{H}_n} & \text{Comp}_n \\
\downarrow{\text{Id}} & & \downarrow{\Phi_n} \\
B_n & \xrightarrow{\Phi_n} & B_n
\end{array}$$  \hspace{1cm} (7.3)

commutes, and we call it the left unit property. For the right unit axiom, we must remember where the unit is being inserted. Recalling the notation of the last section, we may define a right unit $n$-fold functor

$$\mathcal{K}_n : B_0^n \to \text{Comp}_n$$

by

$$\mathcal{K}_n(x, b) = (x, b, \mathcal{I}_n f_b(x)).$$

Then the right unit axiom is the commutativity of the diagram

$$\begin{array}{ccc}
B_0^n & \xrightarrow{\mathcal{K}_n} & \text{Comp}_n \\
\downarrow{\Phi_n} & & \downarrow{\Phi_n} \\
B_n & \xrightarrow{\Phi_n} & B_n
\end{array}$$  \hspace{1cm} (7.4)

where the diagonal $n$-fold functor is the projection.

**Definition 7.2.** For an $n$-actad $\mathcal{C}$, let $\mathcal{C}^0 = \mathcal{C} \times B_n B_0^n$. Then $\mathcal{C}$ is called a unital $n$-actad if there exists an $n$-fold functor lift

$$\mathcal{H}_n^\mathcal{C} : \mathcal{C} \to \text{Comp}_n^\mathcal{C}$$
be defined by

\[ x \mapsto (\mathcal{F}_n^x[|x|], 1, x), \]

where \(|x|\) denotes the projection of \(x\) to \(\mathcal{B}_n\), and

\[ \mathcal{K}_n^\mathcal{F} : \mathcal{F}^0 \to \text{Comp}_n^\mathcal{F} \]

be defined by

\[ \mathcal{K}_n^\mathcal{F} = (x, b, \mathcal{F}_n^x[f_b(x)]), \]

the following diagrams above (7.3) and (7.4) commute:

\[ \begin{array}{ccc}
\mathcal{F} & \xrightarrow{\mathcal{K}_n^\mathcal{F}} & \text{Comp}_n \\
\downarrow & & \downarrow \Gamma \\
\mathcal{F}, & & \mathcal{F},
\end{array} \]

\[ \begin{array}{ccc}
\mathcal{F}^0 & \xrightarrow{\mathcal{K}_n^\mathcal{F}} & \text{Comp}_n \\
\downarrow & & \downarrow \Gamma \\
\mathcal{F}, & & \mathcal{F},
\end{array} \]

where \(\pi\) is the projection.

But now there is also a version of unitality of \(n\)-actads (or plain \(n\)-actads) which includes units coming from \(i\)-actads (or plain \(i\)-actads) for all \(i < n\). I call this concept \(R\)-unitality, where \(R\) stands for “recursive”.

To give an example, a based operad (which, recall, is over \(\mathbb{N}_0\) instead of \(\mathbb{N}\)) is a unital operad \(\mathcal{C}\) with a base point \(* \in \mathcal{C}(0)\). In a way, this comes from the monoid unit, since the free monoid on one generator contains \(1 = a^0\), corresponding to the 0 index. It is interesting to note that the base point of an operad is not subject to any axioms. Yet, it is an important feature, adding a rich structure of “degeneracies” given by plugging in the base point. This structure is crucial in the approximation theorem in infinite loop space theory [26].

To define \(R\)-unital plain actads, we define, simultaneously, the \(R\)-unital plain \(n\)-base \(B^R_n \supset B_n\) with maps

\[ F_n^R : B_n^R \to T_{B_{n-1}^R}, \]

\[ G_n^R : B_n^R \to B_{n-1}^R \]

and the composition \(\circ^n\). Here, \(T_n^X\) is defined in the same way as \(T_X\) (recall Definition 3.3), except that an empty sequence is allowed. In fact, there is a distinguished subset

\[ B^{R,0}_n \subseteq B_n^R \]

such that

\[ x \in B^{R,0}_n \Rightarrow m_x = 0. \]

Now an \(R\)-unital plain actad \(\mathcal{C}\) is defined the same as a unital plain \(n\)-actad with \(B_n\) replaced by \(B_n^R\), together with a section

\[ B^{R,0}_n \to \mathcal{C} \]

over \(B_{n-1}^R\) (by using \(G_n^R\)).
Then $B^R_{n+1}$ is defined as the free plain $R$-unital $n$-actad over $\text{Id}: B^R_n \to B^R_n$, modulo the relations
\[
\gamma_{n,i}(x,y) = x \circ_i^n y \quad \text{for } x \in B^R_n, \ y \in B^R_{n,0}.
\] (7.5)

One defines, inductively,
\[
B^R_{n+1} = B^R_n \amalg \{ 1^n_x | x \in B^R_{n-1} \} \tag{7.6}
\]
(we want to begin the induction with $B^R_0 = \{ *, * \}$ and $B^R_1 = \mathbb{N}_0$). Note that $m_x$ in $B^R_{n+1}$ does not necessarily equal $m_x$ in $B^R_n$. We emphasize that in the second term on the right-hand side of (7.6) we mean the $R$-unital $n$-actad units, not the units $1^n_x \in B^R_n$.

The reason to keep these units separate is to be able to plug into $1^n_x$ when $\circ^{n+1}$ is applied: we have $1^n_x \in B^R_{n+1}$ via the inclusion $B^R_n \subseteq B^R_{n+1}$ with $m_{1^n} = 1$. To explain this, in our definition of trees in $B^R_n$, there is no reason to prohibit plugging a tree with 1 prong into the triangle with one prong (“lozenge”) $1^1_1$ via $\circ^2$. However, plugging in the $R$-unit $1^1_1$ via $\circ^2$ eliminates the lozenge from the tree, which is a new operation.

The structure of $B^R_n$ is not as complicated as it may seem. In fact, one readily proves the following lemma by induction.

**Lemma 7.3.** The canonical inclusion $B_n \subseteq B^R_n \setminus B^R_{n,0}$ is a bijection.

Now $\mathcal{R}^R_n$, $R$-unital $n$-actads (and all the associated functors) can be defined completely analogously to, $\mathcal{R}_n$, $n$-actads, via an inductive definition of $\mathcal{R}^R_n$ (and the associated functors) and then replacing $\mathcal{R}^R_n$ while extending the formula (6.2) to $S$-morphisms with $S \subseteq \{1, \ldots, n\}$. This is then a generalization of (unital) $n$-actads.

In this approach, we keep permutations as the $\{n\}$-morphisms; it is possible to create a larger category generated by these morphisms and $n$-compositions with the various $i$-units ($i < n$), but then we no longer have an invertible cube-like $n$-fold category.

Note that an $R$-unital 1-actad is the same thing as a based operad. 1-morphisms in $\mathcal{R}_2$ together with $\circ_1^n 2^n_1$ and $\circ_2^n 1^n_1$ (with the obvious compatibility relations, by noting that $B^R_{2,0} = \{ 1^n_1, 1^n_0 \}$) generate a larger category of trees, whose opposite is equivalent to a tree analogue of a category of finite sets and injections.

Now we can define higher analogues of a based algebra over a based operad: an $R$-unital algebra over an $R$-unital $n$-actad $C$ is a fibered $(n-1)$-fold category
\[
X \to \mathcal{R}^R_{n-1}
\]
together with a section $(n-1)$-fold functor
\[
\begin{array}{cc}
\mathcal{R}^R_{n-1} & \subset \\
\downarrow & \\
X
\end{array}
\]
which satisfies equivariance and associativity (and unit) properties analogous to those described in Section 4, in addition to the $R$-unitality axiom, which states that if
\[
(y, (x_1, \ldots, x_m)) \in S - \text{Mor}(C \times_{T_n} X)
\]
with $x_i = x \in S - \text{Mor}(\mathcal{R}^R_{n-1})$ and $S \subseteq \{1, \ldots, n-1\}$, then
\[
\Theta(y, (x_1, \ldots, x_m)) = \Theta(\gamma_{n,i}(y, x), (x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_m)).
\]
(Recall that $\Theta$ denotes the functor mapping $C \times_{T_n} X \to X$ in (4.2).)
8 Monads

A key point of the infinite loop space theory of May [26] is the close connection between operads and monads. A monad (for an introduction, see [7, Chapter 4]) in a category \( A \) is a functor \( C : A \to A \) which satisfies monoid-like properties with respect to the composition. Its algebra is an object \( X \) together with a natural transformation \( \Theta : CX \to X \) which satisfies left module-like axioms with respect to the composition.

For a universal algebra in the category of sets, its associated monad \( C \) assigns to a set \( X \) the free algebra \( CX \) of the given type on \( X \). For an operad \( \mathcal{C} \) (in the unbased context), the associated monad \( C \) has a particularly simple form [26]:

\[
CX = \prod_{n \geq 1} \mathcal{C}(n) \times_{\Sigma_n} X^n
\]

(on the right-hand side, the subscript denotes taking orbits).

In this section, we describe the monads associated with \( n \)-actads and plain \( n \)-actads. Let us discuss the plain case first. Let \( \mathcal{C} \) be a plain \( n \)-actad. In this case, we define a monad \( C \) in the category of sets over \( B_{n-1} \). (In particular, we are dealing with multisorted algebras in the sense of [6].) Consider a set \( \Xi : X \to B_{n-1} \) over \( B_{n-1} \). Again, we write, for \( y \in B_{n-1} \), \( X(y) \) for \( \Xi^{-1}(y) \). Then for \( y \in B_{n-1} \),

\[
CX(y) := \prod_{z \in B_i, \, G_i(z) = y} \prod_{i=1}^{m_i} X(f_i(z)).
\]

In the case of an \( n \)-actad \( \mathcal{C} \), we construct the monad \( C \) describing \( \mathcal{C} \)-algebras in the category of \((n-1)\)-fold categories fibered over \( \mathcal{B}_{n-1} \). We could, alternatively, describe a monad in sets over \( B_{n-1} \), considering the \( \{i\} \)-morphisms as unary operations. While this point of view also seems interesting, we do not follow it in the present paper.

Suppose that \( \mathcal{C} \) is an \( n \)-actad. Let \( X \) be an \((n-1)\)-fold category with a fibered \((n-1)\)-fold functor

\( \Xi : X \to \mathcal{B}_{n-1} \).

(Thus, \( X \) is an invertible cube-like \((n-1)\)-fold category.) Now we construct the free \( \mathcal{C} \)-algebra \( CX \) on \( X \). There are \( n \)-fold fibered functors

\[
T_{\Xi} : T_X \to T_{\mathcal{B}_{n-1}},
\]

\[
\Lambda : \mathcal{C} \to T_{\mathcal{B}_{n-1}}.
\]

We can get a \( \Lambda \) since there is an \( n \)-fold fibered functor

\( \mathcal{C} \to \mathcal{B}_{n} \),

which we can compose with

\( \mathcal{F}_n : \mathcal{B}_{n} \to T_{\mathcal{B}_{n-1}} \).

Suppose \( S \subseteq \{1, \ldots, n-1\} \). Then first define an \((n-1)\)-fold category \( C_0 X \) with an \((n-1)\)-fold functor \( \Phi : C_0 X \to \mathcal{B}_{n-1} \) by

\[
S - \text{Mor}(C_0 X) = S - \text{Mor}(\mathcal{C} \times_{\mathcal{B}_{n-1}} T_X)/(x, y) \sim (\tilde{f}(x), \tilde{f}(y)),
\]

where \( x \in S - \text{Mor}(\mathcal{C}) \), \( y \in S - \text{Mor}(T_X) \), \( T_{\Xi}(y) = \Lambda(x) = \alpha \in T_{\mathcal{B}_{n-1}} \), \( (f : \alpha \to \beta) \in S - \text{Mor}(T_X) \) for some \( \beta \), \( \tilde{f} \) is the lift of \( f \) by \( \Lambda \), and \( \tilde{f} \) is the lift of \( f \) by \( T_{\Xi} \).

The trouble is that the \((n-1)\)-fold functor \( \Phi \) satisfies the uniqueness, but not the existence properties of a fibered \((n-1)\)-fold functor, due to the same property of the \((n-1)\)-fold functor

\( \mathcal{F}_n : \mathcal{B}_{n} \to \mathcal{B}_{n-1} \).
Let \( \mathcal{A} \) be a \( k \)-fold category. The forgetful functor

\[ \mathcal{U}_\mathcal{A} : \text{fibered } k \text{-fold categories over } \mathcal{A} \to \text{fibered } k \text{-fold categories over } \mathcal{A} \]

(on both sides, \( k \)-fold functors are morphisms) has a left adjoint \( K_{\mathcal{A}} \).

**Definition 8.1.** For \( k = n - 1 \) and \( \mathcal{A} = \mathcal{B}_{n-1} \), the monad \( C \) in \( (n - 1) \)-fold categories fibered over \( \mathcal{B}_{n-1} \) associated with an \( n \)-actad \( \mathcal{C} \) is given by

\[ CX = K_{\mathcal{B}_{n-1}} C_0 X. \]

Then \( CX \) as defined is the free \( \mathcal{C} \)-algebra on \( X \).

Now let \( \mathcal{C} \) be an \( (n - 1) \)-fold category fibered over \( \mathcal{B}_{n-1} \). Then we have the identity, which is a fibered functor

\[ CX = K_{\mathcal{B}_{n-1}} C_0 X. \]

Now, one can also make a generalization of this construction to iterated algebras. Suppose that \( \mathcal{C} \) is an \( n \)-fold category. Then we have that \( \mathcal{C}^{\alpha_1, \ldots, \alpha_k} \) is a multisorted \( n \)-actad over \( \{1, \ldots, k\} \) (by which we mean an \( n \)-actad in the category of sets over \( \{1, \ldots, k\} \)). From this point of view, we can just repeat the above construction over \( \{1, \ldots, k\} \).

More explicitly, let \( X = (X_1, \ldots, X_k) \) be a \( k \)-tuple of \( (n - 1) \)-fold categories with a fibered \( (n - 1) \)-fold functor

\[ \Xi_j : X_j \to \mathcal{B}_{n-1}. \]

Now let \( X \) also be an \( (n - 1) \)-fold category, where the objects are \( k \)-tuples of objects of \( X_j \)'s in the same order, and the \( S \)-morphisms are \( k \)-tuples of \( S \)-morphisms of \( X_j \)'s also in the same order. So we also have an \( (n - 1) \)-fold fibered functor

\[ \Xi = (\Xi_1, \ldots, \Xi_k) : X \to \mathcal{B}_{n-1} \times \{1, \ldots, k\}. \]

(Thus, \( X \) is an invertible cube-like \( (n - 1) \)-fold category.) Now, we define the free \( \mathcal{C}^{\alpha_1, \ldots, \alpha_k} \) category \( C^{\alpha_1, \ldots, \alpha_k} X \) on \( X \).

Then there are \( n \)-fold, fibered functors

\[ T_\Xi : T^k_X \to T^k_{\mathcal{B}_{n-1} \times \{1, \ldots, k\}}, \]

\[ \Lambda : \mathcal{C}^{\alpha_1, \ldots, \alpha_k} \to T^k_{\mathcal{B}_{n-1} \times \{1, \ldots, k\}}. \]

The construction \( \Lambda \) is as follows. First, by definition, we have

\[ \mathcal{C}^{\alpha_1, \ldots, \alpha_k} = \mathcal{C} \times_T \mathcal{B}_{n-1} \mathcal{C}^{\alpha_1, \ldots, \alpha_k}. \]

Since we have that \( \mathcal{C} \) is an \( n \)-actad in the normal sense, we have a fibered \( n \)-fold functor

\[ \mathcal{C} \to \mathcal{B}_n. \]

Then we would need a fibered \( m \)-fold functor for every \( m \): for every \( k \leq m \) with some \( 1 \leq \alpha_1 < \cdots < \alpha_k \leq m \),

\[ h_m : \mathcal{B}^{\alpha_1, \ldots, \alpha_k}_m \to \mathcal{B}_m \times \{1, \ldots, k\}. \]

For \( m = 1 \), we have that \( k \) must equal 1. In addition, we also must have \( \alpha_1 = 1 \). However, for \( k = 1 \), we have \( \mathcal{B}_1 = \mathcal{B}_1 \). Then we have the identity, which is a fibered functor

\[ \mathcal{B}^{\alpha_1, \ldots, \alpha_k}_m \to \mathcal{B}_m = \mathcal{B}_m \times \{1, \ldots, k\}. \]

Suppose we are given this data for \( m - 1 \). Fix some \( 1 \leq \alpha_1 < \cdots < \alpha_k \leq m \). If \( \alpha_k < m - 1 \), then we have

\[ \mathcal{B}^{\alpha_1, \ldots, \alpha_k}_m \to T^k_{\mathcal{B}_{m-1} \times \{1, \ldots, k\}} \to \mathcal{B}_m \times \{1, \ldots, k\} \]

(8.1)

(8.1)

(8.1)

(8.1)

(8.1)

(8.1)

(8.1)

(8.1)

(8.1)
Now, by Definition 6.1, we have
\[ T_{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}} \to \{1, \ldots, k\} \]
and we can construct
\[ T_{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}} \to T_{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}} \to T_{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}} \]
where the first map is the forgetful functor and the second map is induced by the natural functor
\[ \mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}} \to \mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}} \].

Thus, we can construct a fibered functor
\[ \mathcal{F}_{m-1}^{\alpha_1, \ldots, \alpha_k} \to T_{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}} \times \{1, \ldots, k\}. \tag{8.2} \]

Then we can use the fact that
\[ \mathcal{F}_m : \mathcal{H} \to T_{\mathcal{H}^{m-1}} \]
is a fibered functor, to get a lift of every \( S \)-morphism of \( T_{\mathcal{H}^{m-1}} \) to \( \mathcal{H}_m \). Using this lifting by composing it with the fibered functor of (8.1) or (8.2), we get a fibered functor
\[ h_m : \mathcal{H}^{\alpha_1, \ldots, \alpha_k} \to \mathcal{H}_m \times \{1, \ldots, k\}. \]
(This concludes the inductive definition of \( h_m \).)

At the moment, we use this for \( m = n - 1 \). We have
\[ h_{n-1} : \mathcal{H}^{\alpha_1, \ldots, \alpha_k} \to \mathcal{H}_{n-1} \times \{1, \ldots, k\}. \]
Then we have
\[ \mathcal{F}^{\alpha_1, \ldots, \alpha_k} \to \mathcal{H}_n \times \mathcal{H}_n^{\alpha_1, \ldots, \alpha_k} = \mathcal{H}_n^{\alpha_1, \ldots, \alpha_k}. \]
Then we compose this functor with \( \mathcal{F}_n^{\alpha_1, \ldots, \alpha_k} \) to get a map
\[ \mathcal{H}^{\alpha_1, \ldots, \alpha_k} \to T_{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}} \to T_{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}} \times \{1, \ldots, k\}. \]
Using this, we get our \( \Lambda \).

We still want the free iterated \( \mathcal{C} \)-algebra on \( X \) which we denote by \( C^{\alpha_1, \ldots, \alpha_k}X \) to be an \( (n-1) \)-fold category. So, again, suppose \( S \subseteq \{1, \ldots, n-1\} \). Then define first \( C_0^{\alpha_1, \ldots, \alpha_k}X \) by
\[ S - \text{Mor}(C_0^{\alpha_1, \ldots, \alpha_k}X) = S - \text{Mor}(\mathcal{C}^{\alpha_1, \ldots, \alpha_k} \times_{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}} T_k^{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}}/(x, y) \sim (\tilde{f}(x), \tilde{f}(y)), \]
where \( x \in S - \text{Mor}(\mathcal{C}^{\alpha_1, \ldots, \alpha_k}), y \in S - \text{Mor}(T^{\mathcal{H}^{\alpha_1, \ldots, \alpha_{k-1}}}/(x, y)), \)
\[ T_2(y) = \Lambda(x) = \gamma \in T_{\mathcal{H}^{n-1}}, (f : \gamma \to \delta) \in S - \text{Mor}(T^{\mathcal{H}^{n-1}}/(x, y)) \text{ for some } \delta, \]
\[ \tilde{f} \text{ is the lift of } f \text{ by } \Lambda, \text{ and } \tilde{f} \text{ is the lift of } f \text{ by } T_2. \]

Then we have
\[ C^{\alpha_1, \ldots, \alpha_k}X = K_{\mathcal{H}^{n-1}}(1, \ldots, k-1) C_0^{\alpha_1, \ldots, \alpha_k}X. \]

Now these are analogous unital and \( R \)-unital versions of these concepts imposing additional identifications for the units, analogous to the concept of based algebras over an operad [26]. We omit the details.

9 Case study of a 2-actad algebra

When applying operads to topology, we do not, of course, work in the base category of sets, but rather in topological spaces or simplicial sets. All our definitions in this setting work essentially without change. In particular, geometric realizations of fibered \( n \)-fold functors are still fibered. In the case of spaces, we
require all the structure maps to be continuous. In the case of simplicial sets, we can think of a simplicial object in any of the structures we considered so far, which is considered as a category where morphisms are homomorphisms (i.e., maps preserving the entire structure). This makes sense, since all the structures we considered can be axiomatized as (multisorted) universal algebras. In particular, functors of singular sets and geometric realizations linking the structures in the topological and simplicial context exist and behave in the usual way. One source of examples is the Čech resolution. For a space $X$, $EX$ denotes the simplicial space

$$EX : \Delta^O \to \text{Spaces}$$

with $EX_n = X^{n+1}$ (faces are given by taking an $(n + 1)$-tuple of elements of $X$ to an $n$-tuple that is the original $(n + 1)$-tuple missing a coordinate, and degeneracies are given by taking an $n$-tuple to an $(n + 1)$-tuple which is the same except for having one of the coordinates copied twice). We often identify $EX$ with its geometric realization $|EX|$. The Čech resolution tends to preserve algebraic structures, since the geometric realization of simplicial spaces preserves finite products (at least when we are working in the compactly generated category [33]).

For example, considering the associative $n$-actad we introduced in Section 4, we obtain the $n$-actad $E\mathcal{A}_n$, which we call the $E_{\infty}$-$n$-actad. For example, $E\mathcal{A}_1$ is the Barratt-Eccles operad [27]. As shown in [26, 27], the classifying space $BA$ of a permutative category $A$ is an $E\mathcal{A}_1$-algebra, and hence an $E_{\infty}$-space. (Recall that the classifying space (or nerve) of a category is the simplicial space, where $BA_n$ consists of composable $n$-tuples of morphisms in $A$; meaning objects for $n = 0$, faces are given by compositions or forgetting the first or last morphism, and degeneracies are insertions of identities [26].) For a group $G$ considered as a category with one object, we have an identification

$$BG \cong EG/G,$$

where $G$ acts diagonally on the right-hand side. The bijection is given by homogenization of coordinates

$$(g_1, \ldots, g_n) \mapsto (1, g_1, g_1 g_2, \ldots, g_1 \cdots g_n).$$

A permutative category is a symmetric monoidal category that is strictly associative where the commutativity isomorphism is a strict involution.

Recall the $n$-actad $\mathcal{A}_n$ described in Example 4.2 at the end of Section 4. One may therefore ask what interesting $E\mathcal{A}_n$-algebras there are, what they mean in homotopy theory, and how they arise. In this paper, I give some examples for $n = 2$. Note, however, that for any $n$, inclusion of the simplicial 0-stage gives a morphism of $n$-actads

$$\mathcal{A}_n \to E\mathcal{A}_n. \quad (9.1)$$

Therefore, $E\mathcal{A}_n$-algebras are, in particular, $(n - 1)$-actads, and we can study their algebras. For example, $E\mathcal{A}_2$-algebras are, in fact, operads.

In this section, we study the free $E\mathcal{A}_2$-algebra on a given groupoid $X \to \mathcal{R}_1$, and the simplest non-trivial case of $X$ (the free “binary” case) gives a condition on a category which guarantees that its classifying space is an algebra over the free $E\mathcal{A}_2$-algebra $A_{E\mathcal{A}_2} X$ on $X$. In some sense, this can be thought of as an $E\mathcal{A}_2$ analogue of the results of [27] on the structure of the Barratt-Eccles operad.

In a way, we can think of the operad $A_{E\mathcal{A}_2} X$, for a groupoid $X$, as describing algebras with operations from $X$ which have commutativity properties given by $X$. However, these operations do not have any associativity properties. If we arrange these operations in a planar tree (as in the reverse Polish notation on some old calculators), the $E\mathcal{A}_2$-algebra property says that the order of the operations “does not matter in the $E_{\infty}$-sense”. We see from this example that even for $n = 2$, which is the next stage beyond the well-studied case of $n = 1$, the world of $n$-actads becomes very rich.

To say things more precisely, suppose that $\mathcal{A}$ is a 2-actad. Then suppose that $X$ is a groupoid with a fibered functor

$$X \to \mathcal{R}_1.$$
Then, as noted in Section 8 above, the free \( \mathcal{A} \)-algebra on \( X \) is the operad

\[
A_{\mathcal{A}} X(n) = \Sigma_n \times 1 - \text{Mor}(\mathcal{B}_2) \prod_{T \in B_2, m_{\mathcal{G}_2}(T) = n} \left( \mathcal{A}(T) \times \text{Aut}_2(T) \prod_{i=1}^{m_T} X(f_i(T)) \right).
\]

For \( T \in B_2 = \text{Obj}(\mathcal{B}_2) \), we have \( E_{\mathcal{A}}(T) = \{ T \} \times \text{Aut}_2(T) \) (where \( \text{Aut}_2(T) = \{ 2 \} - \text{Mor}(T,T) \)). So for every \( X \),

\[
A_{E_{\mathcal{A}}2} X(n) = \Sigma_n \times 1 - \text{Mor}(\mathcal{B}_2) \prod_{T \in B_2, m_{\mathcal{G}_2}(T) = n} \{ T \} \times \text{Aut}_2(T) \times \text{Aut}_2(T) \prod_{i=1}^{m_T} X(f_i(T))
\]

\[
= \Sigma_n \times 1 - \text{Mor}(\mathcal{B}_2) \prod_{T \in B_2, m_{\mathcal{G}_2}(T) = n} \{ T \} \times \prod_{i=1}^{m_T} X(f_i(T))
\]

\[
= \Sigma_n \times 1 - \text{Mor}(\mathcal{B}_2) \prod_{T \in B_2, m_{\mathcal{G}_2}(T) = n} \prod_{i=1}^{m_T} X(f_i(T)).
\]

As an example of this, let, for a set \( S \), \( X_S^2 \) be the groupoid fibered over \( \mathcal{B}_1 \):

\[
X_S^2(n) = \emptyset, \quad \text{if } n \neq 2,
\]

and let

\[
X_S^2(2) = S \times \Sigma_2
\]

be the free \( \Sigma_2 \)-set on \( S \). Then let \( \mathcal{C} \) be the underlying operad of the free \( E_{\mathcal{A}}2 \)-algebra on \( X_S^2 \). Then

\[
\mathcal{C}(n) \cong B_2(n - 1)_{\text{binary}} \times \Sigma_n \times \text{B}(\Sigma_{n-1}^S),
\]

where \( \Sigma_{n-1}^S \) is the groupoid given by \( \Sigma_{n-1} \) acting on \( S^{n-1} \), and \( B_2(n)_{\text{binary}} \) are the elements of \( B_2(n) \) which are of the form

\[
((2, 2, \ldots, 2), (i_1, i_2, \ldots, i_{n-1}))
\]

for some \( n \). (Note that \( B_2(n)_{\text{binary}} \) can also be interpreted as the set of binary trees with \( n + 1 \) leaves.)

Let \( Y \) be a groupoid with a map \( \Xi : A \to \text{Funct}(\{ Y \times X, Y \}) \). Let \( \text{proj}_i^2 : S \times S \to S \) be the coordinate projections for \( i \in \{ 1, 2 \} \), and \( \text{proj}_i^3 : S \times S \times S \to S \) be the coordinate projections for \( i \in \{ 1, 2, 3 \} \). When the source is obvious, we simply write \( \text{proj}_i \). We also have maps

\[
\chi_\ell : S \times S \to \text{Funct}(\{ Y \times Y \times Y, Y \}),
\]

\[
\chi_r : S \times S \to \text{Funct}(\{ Y \times Y \times Y, Y \})
\]

given by \( \chi_\ell = (\Xi \circ \text{proj}_2) \circ ((\Xi \circ \text{proj}_1) \times \text{Id}) \) and \( \chi_r = (\Xi \circ \text{proj}_3) \circ (\text{Id} \times (\Xi \circ \text{proj}_1)) \). Note that we apply the argument only to \( \text{proj}_2 \) and \( \text{proj}_1 \), e.g., \( \chi_\ell((s, t)) = (\Xi(t)) \circ (\Xi(s) \times \text{Id}) \) (we will continue to use this convention later). Then let \( T : Y \times Y \to Y \times Y \) be the functor that switches coordinates. We also have maps induced by permutations of operations

\[
\chi_{\ell, r, \ell, r, \ell, r, \ell, r, \ell, r, \ell, r, \ell, r, \ell, r, \ell, r} : S \times S \times S \to \text{Funct}(\{ Y \times Y \times Y \times Y, Y \}),
\]

which are given by

\[
\chi_{\ell, \ell} = (\Xi \circ \text{proj}_3) \circ (\Xi \circ \text{proj}_2 \times \text{Id}) \circ (\Xi \circ \text{proj}_1 \times \text{Id} \times \text{Id}),
\]

\[
\chi_{r, r} = (\Xi \circ \text{proj}_3) \circ (\Xi \circ \text{proj}_2 \times \text{Id}) \circ (\text{Id} \times \Xi \circ \text{proj}_1 \times \text{Id}),
\]

\[
\chi_{\ell, r} = (\Xi \circ \text{proj}_3) \circ (\text{Id} \times \Xi \circ \text{proj}_2) \circ (\text{Id} \times \Xi \circ \text{proj}_1 \times \text{Id}),
\]

\[
\chi_{r, \ell} = (\Xi \circ \text{proj}_3) \circ (\text{Id} \times \Xi \circ \text{proj}_2) \circ (\text{Id} \times \text{Id} \times \Xi \circ \text{proj}_1),
\]

\[
\chi_u = (\Xi \circ \text{proj}_2) \circ ((\Xi \circ \text{proj}_1) \times (\Xi \circ \text{proj}_3)).
\]
Consider the following additional structure on a groupoid $Y$:

1. We have isomorphisms
   \[ \alpha_{\ell} : \chi_{\ell} \to \chi_{\ell} \circ T, \]  
   \[ \alpha_{r} : \chi_{r} \to \chi_{r} \circ T \]  

   with the following commuting diagrams:

   \[ \chi_{\ell} \xrightarrow{\alpha_{\ell}} \chi_{\ell} \circ T \]  
   \[ \downarrow \]  
   \[ \chi_{\ell} \circ T \circ T \]  
   \[ \downarrow \]  
   \[ \chi_{\ell} \]  

   \[ \chi_{r} \xrightarrow{\alpha_{r}} \chi_{r} \circ T \]  
   \[ \downarrow \]  
   \[ \chi_{r} \circ T \circ T \]  
   \[ \downarrow \]  
   \[ \chi_{r} \]

2. The following diagram commutes (and so do the ones similar to it with different choices of $\chi_{?, ?}$):

   \[ \chi_{\ell, \ell} \xrightarrow{\text{Id}} \chi_{\ell, \ell} \]  
   \[ \downarrow \]  
   \[ (\Xi \circ \text{proj}_3)(\alpha_{\ell} \times \text{Id}) \]  
   \[ \downarrow \]  
   \[ \alpha_{\ell} \circ (\Xi \circ \text{proj}_3) \times \text{Id} \times \text{Id} \]  

   \[ \alpha_{\ell} \circ (\Xi \circ \text{proj}_3) \times \text{Id} \times \text{Id} \]  
   \[ \downarrow \]  
   \[ \chi_{\ell, \ell} \circ (T \times \text{Id}) \circ (T \times \text{Id}) \]  
   \[ \downarrow \]  
   \[ \chi_{\ell, \ell} \circ (T \times \text{Id}) \circ (T \times \text{Id}) \]

   \[ (\Xi \circ \text{proj}_3)(\alpha_{\ell} \times \text{Id}) \]  
   \[ \downarrow \]  
   \[ \alpha_{\ell} \circ (\Xi \circ \text{proj}_3) \times \text{Id} \times \text{Id} \]  

   \[ \chi_{\ell, \ell} \circ (T \times \text{Id}) \circ (T \times \text{Id}) \circ (T \times \text{Id}) \]  
   \[ \downarrow \]  
   \[ \chi_{\ell, \ell} \circ (T \times \text{Id}) \circ (T \times \text{Id}) \circ (T \times \text{Id}) \]

3. The following diagram commutes:

   \[ \chi_{u} \xrightarrow{\text{Id}} \chi_{u} \]  
   \[ \downarrow \]  
   \[ \alpha_{\ell} \circ (\text{Id} \times \text{Id} \times (\Xi \circ \text{proj}_3)) \]  
   \[ \downarrow \]  
   \[ \alpha_{r} \circ ((\Xi \circ \text{proj}_1) \times \text{Id} \times \text{Id}) \]

   \[ \alpha_{r} \circ ((\Xi \circ \text{proj}_1) \times \text{Id} \times \text{Id}) \]  
   \[ \downarrow \]  
   \[ \chi_{u} \circ (T \times \text{Id}) \circ (T \times \text{Id}) \]  
   \[ \downarrow \]  
   \[ \chi_{u} \circ (T \times \text{Id}) \circ (T \times \text{Id}) \]

   \[ \alpha_{\ell} \circ (\text{Id} \times \text{Id} \times (\Xi \circ \text{proj}_3)) \]  
   \[ \downarrow \]  
   \[ \alpha_{r} \circ ((\Xi \circ \text{proj}_1) \times \text{Id} \times \text{Id}) \]

   \[ \chi_{u} \circ (T \times \text{Id}) \circ (T \times \text{Id}) \circ (T \times \text{Id}) \]  
   \[ \downarrow \]  
   \[ \chi_{u} \circ (T \times \text{Id}) \circ (T \times \text{Id}) \circ (T \times \text{Id}) \]
Then we claim the following theorem.

**Theorem 9.1.** Given the structure described in the above axioms (1)–(3), the classifying space on morphisms $B(Y)$ is an algebra over the operad $A_{E_6}(X^2_3)$.

The theorem will be proved at the end of this section. To prove the theorem, we first prove some results about $B_2(n)_{\text{binary}}$.

As a warm-up case, consider the usual presentation of the symmetric group

$$\Sigma_n \cong \langle a_1, \ldots, a_{n-1} | a_i^2, a_ia_{i+1}a_i, a_ia_{i+1}, a_ia_ja_ia_j, j > i + 1 \rangle.$$  \hspace{1cm} (9.4)

Here, $a_i$ are understood as switches of consecutive terms in an $n$-element sequence. This can be proved for 4 directly from using the Cayley graph. Then one uses induction and the isotropy groups of elements of $\{1, \ldots, n\}$ in the standard action of $\Sigma_n$ to prove it for every $n$.

In the case of an element of $B_2(n)_{\text{binary}}$, the terms are the triangles (we shall say “nodes”) of a binary tree. Thus, they do not naturally form a sequence but could be thought of as forming a tree themselves where edges are between triangles which are attached. For a given binary tree, we present the group on its nodes in terms of generators which correspond to such edges (of which there are $n-1$).

Concretely, we claim the following theorem.

**Theorem 9.2.** We have

$$2 - \text{Mor}(\mathcal{R}_2(n)_{\text{binary}}) \cong \langle a_1, \ldots, a_{n-1} | a_i^2, a_ia_ja_ia_j, a_i = a_j \text{ when } i \neq j \text{ and } a_i \text{ and } a_j \text{ share a node,} \rangle$$

$$(a_ia_ja_ka_j)^2 \text{ when } i < j < k \text{ and } a_i, a_j \text{ and } a_k \text{ share a node,}$$

$$a_ia_ja_ia_j \text{ when } a_i \text{ and } a_j \text{ do not share a node.}$$  \hspace{1cm} (9.5)

(Here, we denote by $2 - \text{Mor}(\mathcal{R}_2(n)_{\text{binary}})$ the full subcategory of $2 - \text{Mor}(\mathcal{R}_2)$ on binary trees.)

**Comment.** When $a_i$, $a_j$ and $a_k$ share a node with $i$, $j$ and $k$ different, the relation $(a_ia_ja_ka_j)^2$ follows from the relations (9.5) regardless of the order of $i$, $j$ and $k$. This is by the fact that the relations (9.5) involving $a_i$, $a_j$ and $a_k$ generate a copy of $\Sigma_4$, which follows from examining the Cayley graph.

**Proof of Theorem 9.2.** If $n = 4$, this can be proved by drawing the Cayley graph. For $n \geq 5$, suppose that we have a binary tree

$$((x_1, \ldots, x_k), (i_1, \ldots, i_{k-1})) = ((2, \ldots, 2), (i_1, \ldots, i_{k-1})).$$

For lower $n$, assume the claim as an induction hypothesis. Then suppose that we can fix $x_{i-1}, x_i, x_{i+1}, x_{i+2}$ and $x_{i+3}$ with $x_i$ connected to both $x_{i+1}$ and $x_{i+2}$. Then let $a$, $b$, $c$ and $d$ be the 2-morphisms that switch $x_{i-1}$ and $x_{i+2}$, $x_i$ and $x_{i+3}$ and $x_{i+1}$ and $x_{i+2}$, and $x_i$ and $x_{i+1}$, respectively. In a picture, this looks like

$$x_{i-1} \quad a \quad x_i \quad b \quad x_{i+2} \quad c \quad x_{i+3} \quad (9.6)$$

where the dots represent $x_j$’s. Let

$$G_i = \langle a, b, c, d | a^2, b^2, c^2, d^2, (ab)^3, (bc)^3, (ad)^3, (db)^3, (daba)^2, (ac)^2, (cd)^2 \rangle$$  \hspace{1cm} (9.7)

(in our notation here, we rename $x_i$’s after each switch, making the above compositions possible). Then let $G_{i,1}$ be the subgroup of $G_i$ that is generated by $a$, $b$ and $d$. Let $G_{i,2}$ be the subgroup of $G_i$ that is generated by $bd, b$ and $c$. It holds that

$$\kappa_i : G_{i,1} \rightarrow G_{i,2}.$$
with
\[
\begin{align*}
\kappa_i(a) &= b, \\
\kappa_i(b) &= c, \\
\kappa_i(d) &= bdb.
\end{align*}
\] (9.8)

So in other words, \(\kappa_i\) shifts \(x_i\) to \(x_{i+2}\) and takes the permutations around \(x_i\) to those around \(x_{i+2}\).

First, note that by the case \(n = 4\), \(G_{i,1}\) is the symmetric group, and can also be presented only in the relations (9.7) including \(a\), \(b\) and \(d\). We want \(\kappa_i\) to be an isomorphism, so we have to check the relations of \(G_i\) for \(a\), \(b\) and \(d\) for \(\kappa_i(a)\), \(\kappa_i(b)\) and \(\kappa_i(d)\). It is obvious that \((\kappa_i(a))^2 = b^2\) and \((\kappa_i(b))^2 = c^2\) are 1. We have
\[
(\kappa_i(d))^2 = (bdb)^2 = bdbb = bb = 1.
\]

Next, we have
\[
(\kappa_i(a)\kappa_i(d))^3 = (bdbb)^3 = (db)^3 = 1.
\]

Next, we can commute \(d\) and \(c\) since they permute separate pairs of \(x_j\)'s. It holds that
\[
(\kappa_i(d)\kappa_i(a)\kappa_i(b)\kappa_i(a))^2 = bdbbcbcbbdbbcb = bdcbdc = bdcccb = bb = 1.
\]

Now we need to check the Yang-Baxter relations. It is obvious that
\[
\kappa_i(a)\kappa_i(b)\kappa_i(a)\kappa_i(b)\kappa_i(a)\kappa_i(b) = bcbc = 1.
\]

We have
\[
(\kappa_i(d)\kappa_i(b))^3 = (bdcb)^3 = bd(bcbd)^2bc = bd(cbcd)^2bc = bd(cbdc)^2bc = bdc(bd)^2cbc = bcd(bd)^2cbc = (bc)^3 = 1.
\]

So we have every relation. Thus, \(\kappa_i\) is a homomorphism. On the other hand, all of the relations (9.7) are valid in the symmetric group, and thus the image of \(\kappa_i\) must be a symmetric group and \(\kappa_i\) must be an isomorphism.

Now suppose that we have a binary tree in \(B_2(n)_{\text{binary}}\). Represent its triangles as nodes \(x_i\), and edges \(a_i\) between them, where the triangles are attached. Consider a degree three node which is farthest from the root. Using the move (9.6), we can switch one edge in a way that this node moves farther from the root, and the relations coming from the new tree are equivalent to the relations of the old tree. This is because all the relations which change occur in presentations of \(\Sigma_4\) subgroups, which stay isomorphic, as we just proved. (In the end, we also need a variant of the move (9.6) where the edge \(c\) is absent, but that case is clear since we already know the group is \(\Sigma_4\).)

By repeating these moves, the tree can be turned into a sequence, in which case we are reduced to (9.4). \(\square\)

**Proof of Theorem 9.1.** The proof is analogous to the argument of [27] that for a permutative category \(A\), \(BA\) is an \(E\omega\)-algebra. Consider \(n\) composable \(p\)-tuples of \(Y\)-morphisms
\[
\begin{align*}
X_{1,0} \xrightarrow{f_{1,1}} X_{1,1} \xrightarrow{f_{1,2}} \cdots \xrightarrow{f_{1,p}} X_{1,p} \\
&\vdots \hspace{1cm} \vdots \\
X_{n,0} \xrightarrow{f_{n,1}} X_{n,1} \xrightarrow{f_{n,2}} \cdots \xrightarrow{f_{n,p}} X_{n,p}.
\end{align*}
\]

Choose a tree \(T \in B_2(n)_{\text{binary}}\) with \(p + 1\) decorations \(T_0, \ldots, T_p\) of its nodes by elements of \(S\). Apply the operations corresponding to \(T_i\) to the objects \(X_{1,i}, \ldots, X_{n,i}\), and apply the same operations, composed with the appropriate composition of the coherence isomorphisms (9.2) and (9.3), to the morphisms \(f_{1,i}, \ldots, f_{n,i}\). The coherence diagrams (1)–(3) (given in this section, directly before the statement...
of Theorem 9.1) guarantee consistency of these compositions, by Theorem 9.2, thereby describing an $A_{E\mathcal{A}_2}(X^S_k)$-action on $BA$. We construct maps

$$A_{E\mathcal{A}_2}X^S_k(n) \times (BY)^n \to BY.$$  

This completes the proof. □

10 Examples of new operads

In this section, I describe a method for using $E\mathcal{A}_2$ algebras to construct new examples of operads.

First, suppose that $X$ is an operad. Then we have a functor

$$X \to \mathbb{N}$$

(where the morphisms in $\mathbb{N}$ are identities), since we have a projection functor $\mathcal{B}_1 \to \mathbb{N}$.

Then define, for $m, n \in \mathbb{N}$ and $k \in \mathbb{N}_0$,

$$S_k(n, m) = \{(T_0, \ldots, T_k) \mid T_j \in B_2, m = m_{T_j}, G(T_j) = n, \text{there exist permutations } \sigma_j : \{1, \ldots, m\} \to \{1, \ldots, m\} \text{ such that for } j = 1, \ldots, k, f_i(T_0) = f_{\sigma_j(i)}(T_j)\}.$$  

This means that if $(T_0, \ldots, T_k) \in S_k(n, m)$, then $f_i(T_j)$’s are the same as $f_i(T_0)$’s, up to permutation. Then we can define monads $M_k$ in the category of spaces over $\mathbb{N}$ of the form

$$M_kX(n) = \prod_{m} \prod_{(T_0, \ldots, T_k) \in S_k(n, m)} \prod_{i=1}^{m_{T_0}} \Sigma_j \times \prod_{k+1} \Sigma_n X(f_i(T_0))$$

for $k \in \mathbb{N}_0$. The $\Sigma_n$ factors correspond to permutations of “prongs” of the trees $T_0, \ldots, T_k$ (which would arise in the free operad on $\mathcal{B}_1$; see Sections 4 and 8). The monad composition is defined by the 2-composition of trees following the order of the natural numbers $1, \ldots, m_{T_0}$ in the 0-th coordinate, and the order specified by the permutation on $S_k(n, m)$ in the other coordinates. This 2-composition is “twisted” by the 1-permutation of prongs in the $\Sigma_n$ factors (meaning that the successors are switched according to the permutation of the prongs of the inserted tree). The permutations in the resulting $S_k(n, m)$, as well as in the $\Sigma_n$ factors, are then determined as appropriate versions of the wreath product (to match entries which were originally matched). This is obviously associative. We observe that for $k = 0$, algebras over this monad are just operads in the category of spaces, i.e., the monad takes $\prod X(n) \times \Sigma_n$, and then applies the monad defining operads in monoids fibered over $\mathcal{B}_1$, as considered in Sections 4 and 8.

Now let

$$\mathcal{M}_k(\ell_1, \ldots, \ell_m; n) = \prod_{(T_0, \ldots, T_k) \in S_k(n, m), \ell_i = m_{T_i}} \Sigma_j \times \prod_{k+1} \Sigma_n.$$  

(10.1)

Obviously, by counting prongs, we know this is only non-empty when

$$n = \ell_1 + \cdots + \ell_m - m + 1.$$  

(10.2)

Again, $\Sigma_n$’s come from the permutation parts of $T_j$’s. As above, we have $(k + 1)$ copies of $\Sigma_n$ because we have $(k + 1)$ $T_j$’s encoding permutations of “prongs”. The extra $\Sigma_m$ is included so we have $n$ (and not $n - 1$) 2-permutations. We have, for every $k$,

$$\mathcal{M}_k = \mathcal{M}_0 \times \cdots \times \mathcal{M}_0,$$

since the $k$ extra $\Sigma_m$’s on the right-hand side correspond to the $S_k(n, m)$ (instead of $S_0(n, m)$) on the bottom of the coproduct in (10.1). Let

$$\mathcal{M} := \mathcal{M}_0.$$
Now, $\mathcal{M}$ is an $N$-sorted operad (or multi-category, see [13]) and therefore, so is $\mathcal{M}_k$. In addition, we see that $M_k$ is actually the monad associated with $\mathcal{M}_k$ (note, again, that the extra $\Sigma_m$ in (10.1) prevents extra identifications). $\mathcal{M}_0$-algebras are exactly operads, which are $A_2$-algebras.

In fact, every $\mathcal{M}$-algebra is the sequence of spaces (i.e., a space over $N$) of an $A_2$-algebra (i.e., operads). Thus, every $E\mathcal{M}$-algebra is the underlying sequence of spaces of an $EA_2$-algebra. We should explain that this last statement is not “if and only if”. The reason is that the 2-permutations in $M_k$ (or $M_k$) can occur between the “triangles” of different trees $T_i$ and $T_j$. While $m_{T_i} = m_{T_j} = m$, we have no functorial correspondence between the “prongs” of the trees $T_i$ and $T_j$. Therefore, if we allowed these more general 2-permutations in 2-actads, there would be no consistent way of defining $\circ^2$.

Now suppose that we have a spectrum $E$ (for example in the sense of May, see [26–29], i.e., a sequence of spaces $E_n$, $n \in \mathbb{N}_0$ with homeomorphisms

\[ E_n \cong \Omega E_{n+1}, \]

where

\[ \Omega E_{n+1} = \text{Map}_{\text{based}}(S^1, E_{n+1}) \]

denotes the based loop space). Suppose that we have a morphism of spectra

\[ E \to H\mathbb{Z}. \]

Then we have a map

\[ E_0 \xrightarrow{\varphi} \mathbb{Z} \tag{10.3} \]

with

\[ E_0(n) = \varphi^{-1}(n - 1). \]

Now $E_0$ is an algebra over $\mathcal{C}_\infty$, the $\infty$-little cube operad. Now, let $\mathcal{C}$ be an $N$-sorted operad with

\[ \mathcal{C}(\ell_1, \ldots, \ell_m, n) = \mathcal{C}_\infty(m) \]

when (10.2) holds, and $\mathcal{C}(\ell_1, \ldots, \ell_m, n) = \emptyset$ else. Then $(E_0(n))_{n \in \mathbb{N}}$ is a $\mathcal{C}$-algebra.

So we have projections

\[ \mathcal{C} \times E\mathcal{M} \xrightarrow{p_2} E\mathcal{M} \]

\[ \mathcal{C} \xrightarrow{p_1} \mathcal{C}. \]

Then let $N$ be the monad associated with $\mathcal{C} \times E\mathcal{M}$. By (10.1), the symmetric group action on $\mathcal{M}$ is free, so $E\mathcal{M}$ is an $E_\infty$-operad since the Čech resolution of a non-empty space is always (simplicially) contractible. Then the 2-sided bar construction of monads

\[ B(E\mathcal{M}, N, (E_0(n))_{n \in \mathbb{N}}) \cong (E_0(n))_{n \in \mathbb{N}} \]

is an $E\mathcal{M}$-algebra (see [26] for the definition of the 2-sided bar construction). So it is an $E_2$-algebra. The same construction also works for a map of $E_\infty$-spaces $X \to \mathbb{Z}$ in place of $E_0$. (Recall that infinite loop spaces are group-like $E_\infty$-spaces.) Thus, we have the following proposition.

**Proposition 10.1.** Suppose that

\[ X \to \mathbb{Z} \]

is a map of $E_\infty$-spaces. Then there exists an $E_2$-algebra $\Xi_X$ equivalent to $(X(n))_{n \in \mathbb{N}}$. 
We now prove that in some cases, these $E\mathcal{A}_2$-algebras are non-trivial as operads (see (9.1)) in the sense that an $E_\infty$-operad does not map into them.

Let $X$ be the free $E\mathcal{A}_1$-algebra on $\ast$ with

$$X(n) = B\Sigma_{n-1}$$

(which comes with a natural $\Sigma_n$-action). Now we write

$$X_n = X(n+1) = B\Sigma_n = E\Sigma_n \times \Sigma_n \ast,$$

so that, in particular, $X_0 = X(1)$.

**Theorem 10.2.** There does not exist an $E_\infty$-operad $\mathcal{C}$ together with an operad morphism

$$\mathcal{C} \to \Xi_X.$$  \hspace{1cm} (10.4)

**Proof.** Suppose that such a $\mathcal{C}$ does exist. Since $\Xi_X$ is an operad in spaces, we have a $\mathbb{Z}/2$-equivariant map

$$\varsigma : \Xi_X(2) \times (\Xi_X(2) \times \Xi_X(2)) \to \Xi_X(4),$$  \hspace{1cm} (10.5)

where on the right-hand side, $\mathbb{Z}/2 \to \Sigma_4$ acts by sending the generator of $\mathbb{Z}/2$ to the permutation (13)(24). For $\mathbb{Z}/2$-spaces $Z$ and $T$, where $Z$ has a trivial $\mathbb{Z}/2$-action, we have an equivalence

$$Z \times_{\mathbb{Z}/2} (T \times E\mathbb{Z}/2) \simeq Z \times (E\mathbb{Z}/2 \times_{\mathbb{Z}/2} T),$$

or equivalently,

$$(Z \times E\mathbb{Z}/2) \times_{\mathbb{Z}/2} T \simeq Z \times (E\mathbb{Z}/2 \times_{\mathbb{Z}/2} T).$$  \hspace{1cm} (10.6)

By (10.6), we have

$$\varrho : (E\mathbb{Z}/2 \times X_1) \times_{\mathbb{Z}/2} (X_1 \times X_1) \cong X_1 \times (E\mathbb{Z}/2 \times_{\mathbb{Z}/2} (X_1 \times X_1)).$$

We also have a map

$$\nu : E\mathbb{Z}/2 \times_{\mathbb{Z}/2} X_3 \to E\mathbb{Z}/2 \times_{E\mathbb{Z}/2} X_3,$$

since, by construction, the $\Sigma_n$-action on $X(n)$ extends, for every $n$, to an $E\Sigma_n$-action. Let

$$\mu = \nu \circ (E\mathbb{Z}/2 \times \varsigma) \circ \varrho^{-1}.$$

So we have the following diagram:

\[
\begin{array}{ccc}
X_1 \times (E\mathbb{Z}/2 \times_{\mathbb{Z}/2} (X_1 \times X_1)) & \xrightarrow{E\mathbb{Z}/2 \times \varsigma} & E\mathbb{Z}/2 \times_{\mathbb{Z}/2} X_3 \\
\downarrow \varrho & & \downarrow \nu \\
(E\mathbb{Z}/2 \times X_1) \times_{\mathbb{Z}/2} (X_1 \times X_1) & \xrightarrow{E\mathbb{Z}/2 \times \varsigma} & E\mathbb{Z}/2 \times_{\mathbb{Z}/2} X_3 \\
\end{array}
\]

Additionally, by construction, the map $\mu$ comes from the $E_\infty$-algebra (concretely, $\mathcal{C}_\infty$-algebra) structure of $X$. Now, take homology of $\mu$ with coefficients in $\mathbb{Z}/2$, i.e.,

$$H_k(\mu) : H_k(X_1 \times (E\mathbb{Z}/2 \times_{\mathbb{Z}/2} (X_1 \times X_1))) \to H_k(X_3).$$

Now, let $\alpha$ be the generator of $H_0(X_1) = \mathbb{Z}/2$ and let $e_k$ be the generator of

$$H_k(B\mathbb{Z}/2) \cong \mathbb{Z}/2.$$
Then we have
\[ \alpha \otimes (e_k \otimes \alpha \otimes \alpha) \mapsto \alpha \cdot Q^k \alpha \neq 0, \] (10.7)
where \( Q^k \) denotes the Dyer-Lashof operation (see [11,25]).

Now, suppose that we have a map of operads (10.4). Then we have the commutative diagram
\[
\begin{align*}
\mathcal{C}(4) & \longrightarrow X(4) \\
EZ/2 \times \mathbb{Z}/2 \mathcal{C}(4) & \longrightarrow EZ/2 \times \mathbb{Z}/2 X(4)
\end{align*}
\]
commutes. Then the diagram
\[
\begin{align*}
\mathcal{C}(4) & \longrightarrow X(4) \\
EZ/2 \times \mathbb{Z}/2 \mathcal{C}(4) & \longrightarrow EZ/2 \times \mathbb{Z}/2 X(4) \\
E\Sigma_4 \times \Sigma_4 \mathcal{C}(4) & \longrightarrow E\Sigma_4 \times \Sigma_4 X(4)
\end{align*}
\]
commutes. In particular, we have a diagram of the form
\[
\begin{align*}
EZ/2 \times \mathbb{Z}/2 \mathcal{C}(4) & \longrightarrow X(4) \\
E\Sigma_4 \times \Sigma_4 \mathcal{C}(4) & \longrightarrow E\Sigma_4 \times \Sigma_4 X(4)
\end{align*}
\]
in other words,
\[
\begin{align*}
B\mathbb{Z}/2 & \longrightarrow B\Sigma_3 \\
B\Sigma_4 & \longrightarrow
\end{align*}
\]
commutes. So by taking \( \pi_1 \), we get a commutative diagram of groups
\[
\begin{align*}
\mathbb{Z}/2 & \xrightarrow{f} \Sigma_3 \\
\Sigma_4 & \xrightarrow{g} h
\end{align*}
\]

By definition, \( g \) takes the generator of \( \mathbb{Z}/2 \) to \( \sigma = (13)(24) \), \( f \) is an inclusion (by (10.7)), and \( h \) is a group homomorphism. Then \( f = h \circ g \). We have that \( \sigma = \sigma_1 \circ \sigma_2 \), where \( \sigma_1 = (13) \) and \( \sigma_2 = (24) \). Since \( h \) is a group homomorphism, it takes \( \sigma \) to \( h(\sigma_1) \circ h(\sigma_2) \), and \( h(\sigma_1), h(\sigma_2) \) are conjugate in \( \Sigma_3 \),
since $\sigma_1$ and $\sigma_2$ are conjugate in $\Sigma_4$. Thus, $h(\sigma_1)$ and $h(\sigma_2)$ are both non-trivial. However, a non-trivial involution in $\Sigma_3$ is not a composition of two non-trivial involutions, which leads to a contradiction. \[\square\]

Let us add a few words on the topological interpretation of $\Xi_X$-algebras, where $\Xi_X$ is the operad associated with an $E_\infty$-space $X = (X_n)_{n \geq 0}$. First, let us discuss the case where $X = E_0$ for a spectrum $E$ with a morphism of (connective) spectra

$$E \to H\mathbb{Z}. \quad (10.8)$$

This gives a morphism of $E_\infty$-spaces $\varphi : E_0 \to \mathbb{Z}$, and as above, we adopt the convention

$$X(n) = X_{n-1} = \varphi^{-1}(n-1)$$

for $n \in \mathbb{Z}$. In particular, $X_0$ is an $E_\infty$-space (over $\mathbb{Z}$) which is the 0-space of the fiber $\tilde{E}$ of the morphism of the spectra (10.8). While we set up our formalism in such a way that 0 is not included in the indexing of an operad, completely analogously, one can also construct a based operad $\bar{\Xi}_X$ indexed by $n \in \mathbb{N}_0$ with

$$\bar{\Xi}_X(0) \sim X_{-1}.$$  

For a $\Xi_X$-algebra $Y$, $Y \amalg X_{-1}$ is canonically a $\bar{\Xi}_X$-algebra. Now we have already mentioned the fact that when (10.8) splits, $\bar{\Xi}_X$-algebras are equivalent to $E_\infty$-spaces $Y$ together with $E_\infty$-maps

$$\tilde{E}_0 \to Y.$$  

For a general morphism (10.8), a splitting can be achieved by replacing $E$ with the homotopy pushout $\tilde{E}$ of the diagram

$$\begin{array}{ccc}
\tilde{E} & \rightarrow & E \\
\downarrow & & \downarrow \\
E & \rightarrow & \mathbb{Z}
\end{array}$$

Then $X$ gets replaced with $\tilde{X}$, where for $n \in \mathbb{Z},$

$$\tilde{X}(n) = \tilde{X}_{n-1} = \varphi^{-1}(n-1).$$

Then a $\bar{\Xi}_X$-algebra $Y$ is equivalent to a morphism of $E_\infty$-algebras $X \to Y$. However, if we denote the monads associated with the operads we considered by replacing the symbol $\Xi$ with $\Theta$, then for a $\bar{\Xi}_X$-algebra $Y$,

$$\tilde{Y} = B(\Theta \tilde{X}, \Theta Y) \quad (10.9)$$

gives a diagram of $E_\infty$-spaces

$$\begin{array}{ccc}
X & \rightarrow & \tilde{Y} \\
\downarrow & \swarrow & \downarrow \psi \\
\mathbb{Z} & \rightarrow & Y
\end{array} \quad (10.10)$$

Moreover, we get a canonical equivalence

$$\psi^{-1}(-1) \sim Y.$$  

Thus, we see that $\bar{\Xi}_X$-algebras $Y$, where $\pi_0 Y$ is a group, are canonically identified, up to equivalence, with fibers of $-1$ in diagrams of $E_\infty$-spaces of the form (10.10). Such spaces are, of course, homotopically equivalent to the fibers

$$Y' = \psi^{-1}(0),$$
which are equivalent to $E_\infty$-morphisms

$$X_0 \to Y'.$$

However, when (10.8) does not split, the homotopy equivalence $Y \simeq Y'$ is not canonical.

Finally, let us comment what happens when the $E_\infty$-space $X$ is not the 0-space of a spectrum (i.e., is not group complete). Then $\Xi_X$ does not make sense as above, as the $\Xi_X$-algebra $Y$ is necessarily unbased. However, if $X^g$ is the infinite loop space associated with $X$ (i.e., its group completion), then applying $B(\Theta_X^g, \Theta_X^g, ?)$ in the above sense gets us into the above situation. In particular, the $\pi_0$ of

$$Y_+ = Y \amalg \{\ast\}$$

is still canonically a monoid, and its group completion is canonically equivalent to $\psi^{-1}(-1)$ in the diagram (10.10), where $X$ is replaced with $X^g$.

11 Ordinals

In this section, we consider the plain non-unital $n$-base $B_n$ only. Let Ord denote the set of ordinals. It is well known that ordinal numbers $\alpha \in (0, \varepsilon)$ can be written uniquely as a sum

$$\alpha = \omega^{\alpha_1} + \cdots + \omega^{\alpha_k}$$

for some $\alpha > \alpha_1 \geq \cdots \geq \alpha_k$. Now, by definition, every tree in $B_2$ can be written as

$$z = \gamma_{1, i_1} \cdots \gamma_{1, i_2} (\gamma_{1, j_1} (z_0, z_1), z_2), \ldots, z_\ell)$$

(11.1)

with $i_1 > \cdots > i_\ell$, $z_0 \in B_1 = \mathbb{N}$ and $z_1, \ldots, z_\ell \in B_2$ (so all the $z_1, \ldots, z_\ell$ are plugged directly into $z_0$). So if we define inductively a function $\Phi_2 : B_2 \to \text{Ord}$ by $\Phi_2(n) = n$ for $n \in \mathbb{N}$,

$$\Phi_2(z) = (i_1 - 1) + \omega^{\Phi_2(z_1)} + (i_2 - i_1 - 1) + \omega^{\Phi_2(z_2)} + \cdots$$

$$+ (i_\ell - i_{\ell - 1} - 1) + \omega^{\Phi_2(z_\ell)} + (z_0 - i_\ell),$$

then $\Phi_2$ is onto $\varepsilon$. We could identify a subset on $B_2$ on which $\Phi_2$ is bijective, but it will not be bijective on all of $B_2$ because of the order of summation, and also non-cancellation, for example,

$$1 + \omega = \omega.$$

It is therefore natural to investigate how this fact can be generalized to $n > 2$. We focus on the surjectivity part here. For $n > 2$, we introduce more arguments to the function

$$\Phi_n : B_n \to \text{Ord}$$

for the purpose of induction.

To be more precise, let $\varphi_\alpha : \text{Ord} \to \text{Ord}$ be the functions with

$$\varphi_1(\beta) = \omega^{1+\beta},$$

and $\varphi_\alpha(\beta) = \beta$-th fixed point of all $\varphi_{\alpha'}$’s, where $\alpha' < \alpha + 1$. The $\varphi_\alpha$’s are the Veblen functions with the subscripts shifted by 1 for $\alpha \geq 2$. For every $\alpha \in \text{Ord}$, $\varphi_\alpha$ is continuous and strictly increasing.

We now define functions

$$\Phi_n : B_n \to \text{Ord}$$

inductively.

For $x \in B_1$ and $\alpha_1, \ldots, \alpha_{m_x} \in \text{Ord}$, define

$$\Phi_1(x; \alpha_1, \ldots, \alpha_{m_x}) = \alpha_1 + \cdots + \alpha_{m_x}. $$
Now, suppose that we define $\Phi_{n-1}(z; \alpha_1, \ldots, \alpha_{m_z})$ for every $z \in B_{n-1}$ and $\alpha_1, \ldots, \alpha_{m_z} \in \text{Ord}$. Fix $z \in B_n$ and $\alpha_1, \ldots, \alpha_{m_z} \in \text{Ord}$.

We can always write

$$z = ((z_0, z_1, \ldots, z_\ell), (i_1, \ldots, i_\ell))$$

with $i_1 > \cdots > i_\ell$, $z_0 \in B_{n-1}$ and $z_1, \ldots, z_\ell \in B_n$. Let

$$\beta_{i,j} = \alpha_1 + m_{z_1} + \cdots + m_{z_{i-1}} + j.$$ 

Define inductively

$$\Phi_n(z; \alpha_1, \ldots, \alpha_{m_z}) := \Phi_{n-1}(z_0; 1, \ldots, 1, \varphi_{n-1}(\Phi_n(z_1; \beta_{1,1}, \ldots, \beta_{1,m_{z_1}})), 1, \ldots, 1, 1, \ldots, 1, \varphi_{n-1}(\Phi_n(z_2; \beta_{2,1}, \ldots, \beta_{2,m_{z_2}})), 1, \ldots, 1, \ldots, 1, \varphi_{n-1}(\Phi_n(z_\ell; \beta_{\ell,1}, \ldots, \beta_{\ell,m_{z_\ell}}))).$$

Note that not all of the arguments get used in the definition. However, I do not think that eliminating this “wastefulness” would extend the range of ordinals expressible by $B_n$.

**Theorem 11.1.** Fix an $n$. Then for every $\beta \in \text{Ord}$, there exist some $z \in B_n$ and some $\alpha_i \in \{1\} \cup \text{Im}(\varphi_n)$ such that

$$\beta = \Phi_n(z; \alpha_1, \ldots, \alpha_{m_z}).$$

**Proof.** Induction. Suppose $n = 1$. Then

$$\Phi_1(n; \alpha_1, \ldots, \alpha_n) = \alpha_1 + \cdots + \alpha_n.$$ 

Then for every $\beta \in \text{Ord}$, there exist an $n$ and

$$\alpha_1, \ldots, \alpha_n \in \{1\} \cup \{\omega^\alpha \mid \alpha \in \text{Ord}\} = \{1\} \cup \text{Im}(\varphi_1)$$

such that

$$\beta = \alpha_1 + \cdots + \alpha_n.$$ 

Now, suppose that for every $\beta \in \text{Ord}$, there is a $z \in B_{n-1}$, and

$$\alpha_1, \ldots, \alpha_{m_z} \in \{1\} \cup \text{Im}(\varphi_{n-1})$$

with

$$\beta = \Phi_{n-1}(z; \alpha_1, \ldots, \alpha_{m_z}).$$

If $\alpha_1, \ldots, \alpha_{m_z} = 1$, we are done. Suppose

$$\alpha_i = \varphi_{n-1}(\alpha'_i).$$

If $\alpha_i = \alpha'_i$, then $\alpha_i$ is a fixed point of $\varphi_{n-1}$. So there exists an $\alpha''_i$ with

$$\alpha_i = \varphi_n(\alpha''_i).$$

So we are done. Suppose $\alpha'_i < \alpha_i$. Then we use the induction hypothesis on $\alpha'_i$. \qed
By Theorem 11.1, the image of the function

$$\Phi_n : B_n \rightarrow \text{Ord}$$

given by

$$\Phi_n(x) := \Phi_n(x; 1, \ldots, 1)$$

is $\varphi_n(0)$ for $n = 1, 2, \ldots.$

**Comment.** It is readily possible to extend the description of $B_n$ (and, in addition, $\mathcal{R}_n$) to $B_\alpha$ (and $\mathcal{R}_\alpha$) for $\alpha \in \text{Ord}$, by taking unions for limit ordinals $\alpha$. Then also our definition of $\Phi_n$ extends to $\Phi_\alpha$, $\alpha \in \text{Ord}$. Therefore, the first ordinal $\gamma$ for which $\text{Im}(\Phi_\gamma) = \gamma$ is the Feferman-Schütte ordinal $\gamma = \Gamma_0$.

This can be compared with [22], where the authors considered the similar concept of opetopes and possible machine implementations.

**Acknowledgements** The author thanks the referees for many helpful suggestions for improving the presentation of this paper.
