Abstract - Detecting objects in real-time and converting them into an audio output was a challenging task. Recent advancement in computer vision had allowed the development of various real-time object detection applications. This paper describes a simple android app that would help the visually impaired people in understanding their surroundings. The information about the surrounding environment was captured through a phone camera where real-time object recognition through tensorflow’s object detection API was done. The detected objects were then converted into an audio output using android’s text to speech library. Tensorflow lite made the offline processing of complex algorithms simple. The overall accuracy of the proposed system was found to be approximately 90%.

Keywords - Tensorflow, TensorFlow Lite, Machine learning, Computer vision, Object recognition, and Android

1. Introduction

Out of all the human senses eyesight is the most important sense. It allows a person to analyze and understand their surrounding environment. At least 285 million people are facing eyesight challenges or are visually impaired as per the data gathered from WHO. Eyesight issues can cause disturbance in the daily activities of a person. Identifying objects in day-to-day lives, reading text, crossing a road are a few examples of such problems. The proposes system is a simple android based object detection application names “digital eyes” to help the visually impaired. This application tries to replicate the human eye with the help of a smartphone camera using object detection. The normal life of the people can be improved by using modern computer vision techniques. Object detection is one of the methods of computer vision which is having many broader applications over recent years. Object detection technology [3] uses the contrasting features intensity, edge, and shape to recognize the object from the input image. The advancement in object detection algorithms has enabled us to incorporate complex algorithms into an android application. The SSD algorithm and the trained tensorflow models are used for object detection in our android application. Image processing techniques are now currently being used in object detection domain for various applications [4], which are used for social and many other applications. The purpose of this project is object detection for the visually impaired by using speech feedback and extracting features from live camera feed. The application is easy to use and it is equipped with speech synthesizing so that the detected object is communicated to the
blind people as voice output. In section ii, describes a comparative study of several object detection methods and their statistics in tabular format. Section iii describes the system description along with the technology stack uses in the system. In sections iv and v, this papers explains about the advantages and disadvantages of the proposes system in this paper. In section vi it explains the proposes system technically giving an idea about the important components in the system followes by a conclusion and future scope.

2. Related work of different algorithms

Table no. 1. Related work of different algorithms [13]

| Model       | Latency | mAP | FPS | Real-Time |
|-------------|---------|-----|-----|-----------|
| R-CNN       | High    | ~60 | <1  | NO        |
| Fast R-CNN  | Medium  | ~70 | <1  | NO        |
| Faster R-CNN| Medium  | ~70 | 7   | NO        |
| YOLO        | Low     | ~60 | 46  | YES       |
| SSD         | Low     | ~74 | 59  | YES       |

The table above shows the comparison of the various models regarding latency, average accuracy (map), images per second (FPS), and whether they could been used in real-time or non-real-time applications. Analysis of the outcome of a system or algorithm was based on certain parameters. The most common parameters were efficiency, time, resources, accuracy, etc. that were undertaken in almost all analyses. On applying the general parameters over the R-CNN method of objected detection, the results showed that it was much faster than the old methods based on the classification methods. Instead of a huge number of regions, RCNN used the selected searched to retrieved only 2000 regions per frame. So the feature extraction would run over only 2000 regions. A new version of R-CNN called fast R-CNN was far better than R-CNN as it did not transmit 2000 regional proposals to CNN each time. Instead, the CNN operation was carried out once per frame. The implementation of the new method was similar to the previous methods but instead of a selective searched algorithm, an independent network was used to anticipate the proposed regions. A new method you only looked once (YOLO) was proposed for the recognition of the objects. As the above methods used the suggested regions to identified the objected in the image, it never considers the entire image. Regions with a high likelihood of having objects were instead passed through the system for objected detection. But in yolo there was only a single convolutional network and the entire image was analysed by that network [13]. SSD was very closed to r-CNN in terms of accuracy. This made SSD the best algorithm that balances speed and accuracy. Due to this, the SSD algorithm was used widely in objected detection systems.

3. System description

3.1 Object Detection

Object detection is a computer technology relates to computer vision and image processing that deals with detecting the presence of objects with a limitative box and types or classes of objects locates in an image in digital images and videos [5]. Using object detection visually, impaires users can understand their surrounding environment without any challenges and remain independent of others

Input: a picture with one or several objects, like a photograph.

Output: one or more limiting boxes (e.g., defines by a dot, width and height) and a class label for each limiting box.

3.2 Tensorflow

Tensorflow is an open-source software library framework, which was uses to implement object detection and recognition. This consists of pre pre-trained object detection model, which uses an SSD algorithm to detect objects more efficiently and accurately. This method of object detection uses the COCO mobile net SSD v1 model, which also consists of datasets of 80 object categories, which are commonly found around us.

3.3 Android Studio

Android SDK is being uses to make the android application, which can be easily uses by visually impaired users for detecting objects and understanding their surrounding environment. The application’s front end and backend are implemented using this platform. This platform provides all the libraries and packages requires for implementing this system.

3.4 Mobile device-based object recognition

With the ever-increasing advance in smartphone technology, many have tried to implement identification of objects on smartphones [14]. Thanks to smartphones, applications adapted to the blind can be make user-friendly, portable and widely available, eliminating the needs for special equipment to do the processing. However, because of a mobile phone’s limited processing power, some such applications rely on a client-server architecture [19]. One such well-known application is google goggles, which requires an internet connection and cannot add new images to the application database. In another relates paper [6], the authors design a mobile application that can identify paper bills of different denominations to help the blind user make cash exchanges
safely. However, there has been little research into developing systems for visually impaired users that utilize only local processing bases on the calculation resources of a smartphone like in this document an application was developed for android, that performs all the processes locally giving the end result in the form of auditory feedback [5]. This implementation uses the functionalities of the SIFT. However, the work proposes in this document is not dedicated to real-time processing. Commercial object recognition applications are available to blind individuals. Two purpose-based apps were developed by Looktel with a particular focus on the visually impaired and they are: Looktel recognizer and Looktel money reader, which was designed for IOS-enabled devices. Both applications perform in real time and do not require an internet connection to operate. Looktel recognition [17] works by pronouncing object names when they are paired to a database that is normally pre-built for the user by a blind person.

4. Proposed system

The system was implemented in an android app that detects diverse objects in real time with a real-time text reader. In proposed system an object detection android app was developed using google’s tensorflow object detection API model which implemented using SSD algorithm and real-time text reader feature which was using google’s TTS engine and google played services mobile vision API which describes the used of text recognizer class to detect texts from a real-time video feed. SSD algorithm based object detection model was used for real-time and offline object detection.

4.1. System Overview

The system uses a smartphone to capture incoming data in real time. The application gives two options to the user for detecting objects and reading the text. The camera of the application is automatically accessible and it begins to capture the surrounding objects and texts. Data is sent to the TensorFlow object detection model for processing and later it identifies the class of the objects detected and returns the output as spoken feedback. In the case of reading text, it uses Google play services mobile vision API which consists of TextRecognizer class to detect texts from real-time video feed and sends it to google’s TTS (text-to-speech) engine for converting text to speech and thus reads out the text detected by the phone’s camera.

4.2. Implementation

The system was implemented by combining various technological stacks, which are discussed below. Android studio is used for developing the application because it is the official embedded development environment (IDE) designed specifically for developing Android applications. [8]. The Android framework supports capturing images and video through the android.hardware.camera2 API or camera Intent. It is a package used for capturing real-time video for object detection and reading text. TensorFlow library is used for implementing object detection models inside the android application. It provides high-performance numerical computation. It has a flexible architecture which makes easy deployment of computation across a variety of platforms possible [9]. SSD-MobileNet-COCO model is used to process the video in real-time. The SSD architecture is a single convolution network that learns to predict bounding box locations and makes a prediction of the detected object in the form of bounding boxes [12]. The system makes use of two modules object detection and a real-time text reader.

4.2.1 Object Detection: The application makes use of the SSD-MobileNet-COCO model detecting objects. It utilizes only one neural network for the entire input image. The network then divides the input image into several different regions and prediction of boundary areas in the form of squares with their probability score [12].

4.2.2 Text Reader: The text reader reads the data in real time with this approach as the user can easily read the menu cards
in restaurants, hotel room numbers, or even read a paper document, etc. The android app uses Google Mobile Vision API for Optical character recognition (OCR). The Mobile Vision Text API delivers powerful and reliable OCR capability to Android developers that runs on most Android devices.

TextRecognizer: This object processes the images and determines the text contained therein. Once initialized, it can be used to detect text in all picture types. Reading text feature was implemented using Google Text-to-Speech, which speaks the detected text and acknowledged objects.

4.3. Dataset
In this project, the Common Object in Context (COCO) dataset was used to perform the training on SSD MobileNet model, which recognizes 80 different categories [22].

5. Analysis of system
In this project, Tensorflow’s Object detection model was used which used SSD algorithm in the backend, and it was able to work by balancing between accuracy and speed. This model, successfully detects approximately 81 objects. This model has 74.3 mAP (Mean Average Precision) value, which is highest among the models targeted for real-time processing. After implementing this project, it was expected for a speech feedback for the object which were being detected. But same object was getting called out for multiple times as it gets detected. But it will be undesirable to speaking out the same object name even if detection result is same. Also, it was undesirable if two object names spoken are overlapping or very closely that user would not able to distinguish. To solve this problem, if one object was getting detected in first frame and was speaking out. Then program will not speak out its class for next five seconds, even if it gets detected. By this the problem of detecting single object multiple times was being solved. Following are some of the results which shows the prediction value of detecting an object accurately. Thus giving us an idea about the accurate performance from the model while detecting objects correctly. Possible Objects can be detected at a time but only object which was having precision value higher than fixed threshold value will be told to visually impaired user using voice output feedback. Multiple objects can even be accurately detected at a single time.

| Objects | Normal | Dark | Shadowed object | Long dist. |
|---------|--------|------|-----------------|------------|
| Mobile  | 95%    | 81%  | 78%             | 66%        |
| Person  | 93%    | 78%  | 71%             | 73%        |
| Dog     | 89%    | 77%  | -               | 69%        |
| Orange  | 92%    | 82%  | 67%             | 65%        |
| Laptop  | 96%    | 88%  | 75%             | 69%        |
| car     | 91%    | -    | -               | 74%        |
6. Conclusion

In this paper, a model, which was using SSD algorithm, was made use for creating an application for object detection, which uses TensorFlow object detection API for working offline, and giving maximum accuracy as possible. An object detection API was used for the purpose of detecting objects. The future work includes further enhance the efficiency of the model by training a big number of images, working on live stream image capturing and recognition, and training the model a higher number of steps for better results. This system’s voice synthesis provides convenience features for the visually impaired. Tensorflow lite module was used to create a mobile compatible object recognition model for easy use by visually impaired users. The Android application can be further improved on its stability and functionality.

7. Future scope

For security reasons, wired serial communications were used instead of a wireless server. If the information is linked to a server, it could be leaked onto the Internet. Since the information in question contains a lot of privacy and camera-based observations, such leaks could create critical security issues for users. However, a wired connection can secure the information by keeping it offline [13]. Continuous research is expected to solve server security problems, eliminate blind spots in observations by connecting Internet of Things (IOT) cameras to a secure network, and increase precision in object recognition [18]. This study can be used widely to provide the blind with privacy and convenience in everyday life. With the addition of a face recognition feature, the application can be trained to store information on people closely associated with the person, which would help them to distinguish between peers and outsiders.
