Abstract

In this paper, we study the performance of spatial modulation based on reconfigurable antennas. Two main contributions are provided. We introduce an analytical framework to compute the error probability, which is shown to be accurate and useful for system optimization. We design and implement the prototype of a reconfigurable antenna that is specifically designed for application to spatial modulation, and that provides multiple radiation patterns that are used to encode the information bits. By using the measured antenna radiation patterns, we show that spatial modulation based on reconfigurable antennas work in practice, and that its performance can be optimized by appropriately optimizing the radiation patterns to use for a given data rate.

Keywords: Spatial modulation; reconfigurable antennas; antenna prototype; error probability

1 Introduction

Spatial Modulation (SM) \cite{1} is a promising low-complexity \cite{2} and energy-efficient \cite{3} multiple-antenna modulation scheme, which is considered to be especially suitable for application to the Internet of Things (IoT) \cite{4}. For these reasons, SM has attracted the attention of several academic and industrial researchers \cite{5}. A comprehensive description of the main achievements and latest developments on SM research can be found in \cite{6}- \cite{10}. Some pioneering and recent experimental activities can be found in \cite{11}- \cite{14}. The research literature on SM is vast, and various issues have been tackled during the last few years, which include the analysis of the error probability \cite{15}, the design and analysis of transmit-diversity schemes \cite{16}, \cite{17}, and the analysis and optimization of the achievable rate \cite{18}, \cite{19}. A recent comprehensive literature survey on SM and its generalizations is available in \cite{10}.

Among the many SM schemes that have been proposed in the literature, an implementation that is suitable for IoT applications is SM based on reconfigurable antennas (RectAnt-SM) \cite{21}. In SM, the information bits are encoded onto the indices of the antenna elements of a given antenna-array. In RectAnt-SM, by contrast, the information bit are encoded onto the radiation patterns (RPs) of a single-RF and reconfigurable antenna. This implementation have several advantages, especially for IoT applications \cite{4}.

In spite of the potential applications of RectAnt-SM in future wireless networks, to the best of the authors knowledge, no analytical framework for computing the error
probability of this emerging transmission technology is available. In the present pa-
per, motivated by these considerations, we introduce an analytical framework that
allows us to estimate the performance and to optimize the operation of RectAnt-
SM. We prove, in particular, that the diversity order of RectAnt-SM is the same
as the diversity order of SM, which coincides with the number of antennas at the
receiver.

In order to substantiate the practical implementation and performance of
RectAnt-SM, we design a single-RF and reconfigurable antenna that provides us
with eight different RPs for encoding the information bits at a low-complexity
and high energy-efficiency. The proposed antenna is designed, and a prototype is
implemented and measured in an anechoic chamber. Based on the manufactured
prototype, we employ the measured RPs to evaluate the performance of RectAnt-
SM. With the aid of our proposed analytical framework, in particular, we show
that the error probability can be improved by appropriately choosing the best RPs,
among those available, that minimize the average bit error probability.

Together with [4], the results contained in the present paper constitute the first
validation of the performance of RectAnt-SM by using a realistic reconfigurable
antenna that is capable of generating multiple RPs with adequate spatial charac-
teristics for modulating information bits.

The remainder of the present paper is organized as follows. In Section 2, the
system model is introduced. In Section 3, the analytical framework of the error
probability is described. In Section 4, the prototype of the single-RF and recon-
figurable antenna is presented. In Section 5, numerical results are illustrated, and
the performance of RectAnt-SM is analyzed. Finally, Section 6 concludes the paper.

Notation: We adopt the following notation. Matrices, vectors, and scalars are
denoted by boldface uppercase (e.g., $\mathbf{A}$), boldface lowercase (e.g., $\mathbf{a}$), and lowercase
respectively (e.g., $a$). The element $(u, v)$ of a matrix $\mathbf{A}$ is denoted by $\mathbf{A}_{u, v}$, and the
$u$th entry of a vector $\mathbf{a}$ is denoted by $a_u$. The transpose, complex conjugate, and
complex conjugate transpose of $\mathbf{A}$ are denoted by $\mathbf{A}^T$, $\mathbf{A}^*$ and $\mathbf{A}^H$ respectively.
The absolute value of a complex number $a$ is defined by $|a|$. $\mathbb{E}_a \{ \cdot \}$ and $\mathbb{E}_A \{ \cdot \}$
denote the expectation operator of random variable $a$ and matrix $\mathbf{A}$, respectively.
$j = \sqrt{-1}$ is the imaginary unit. Pr $\{ \cdot \}$ denotes probability. $()$ denotes the binomial
coefficient. The Q-function is defined as $Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^\infty \exp \left(-\frac{u^2}{2}\right) du$. The
moment generating function (MGF) of random variable $X$ is defined as $M_X (s) = \mathbb{E}_X \{ \exp (-sX) \}$. The Gamma function is defined as
$\Gamma(z) = \int_0^\infty x^{z-1} e^{-x} dx$. The modified Bessel function of order zero is defined as $I_0 (\cdot)$.

2 System Model
In this section, we introduce the signal model, the channel model, and the demod-
ulator.
2.1 Signal Model

Let us consider an $N_r \times N_t$ multiple-input-multiple-output (MIMO) system that uses a $M$-ary signal constellation diagram. In a conventional SM transmission scheme [1] the data stream is divided into two blocks, where first block of $\log_2(N_t)$ bits is used to identify the index of the transmitted antenna and $\log_2(M)$ bits are used to identify a symbol of the signal constellation diagram. By assuming that channel state information (CSI) is known at receiver, the objective of the detector is to jointly estimate the active antenna and the data symbol that is transmitted in order to retrieve the entire transmitted bitstream.

Let us now consider the RecAnt-SM transmission scheme. In this case, we consider that the transmitter is equipped with a reconfigurable antenna that is capable of generating $P$ different RPs. In this case, the RP that is used for transmission is also used to encode the information, in addition to the signal constellation diagram [20]. More precisely, the joint combination of antenna’s RP and channel constitute the physical resource that is used to encode the information bits. If $P$ RPs are available, then $\log_2(P) + \log_2(M)$ bits of information can be transmitted.

Compared with conventional SM, RecAnt-SM has the advantage of not requiring an array of antennas to enhance the data rate. In addition, RecAnt-SM can be implemented at a low cost, by using simple and compact antennas, where different RPs can be obtained by realizing appropriate circuits that modify the current flowing through the physical antenna. These specific features of RectAnt-SM make it useful for IoT applications. In the sequel, we will discuss an antenna that we have designed and fabricated and that allows us to implement RectAnt-SM in practice. As an example, let us consider $P = M = 4$. Then, $\log_2(P) = 2$ bits are used to identify the RP and $\log_2(M) = 2$ are used to identify a symbol of the signal constellation diagram. Fig. 1 illustrates a simple example of implementation of RectAnt-SM, by focusing only on the RPs, e.g., RectAnt-SSK (space shift keying).

Let us assume that the $p$th RP and the symbol $x_m$ are selected based on information bits to be transmitted. The $N_r \times 1$ received signal vector can be formulated as follows:

$$
\mathbf{y} = \sqrt{\rho} \mathbf{He}_p x_m + \mathbf{w}
$$

(1)

where $\rho$ is the average signal-to-noise-ratio (SNR) at each receive antenna; $\mathbf{w}$ is the $N_r \times 1$ complex additive white Gaussian noise vector of zero mean and unit variance; $\mathbf{e}_p$ for $p = 1, \ldots, P$ is a $P \times 1$ vector whose $p$th entry is equal to one and the other entries are equal to zero; and $\mathbf{H}$ is the $N_r \times P$ channel matrix that accounts for the antenna RPs as well. The vector $\mathbf{e}_p$ allows one to select the specific RP given the bits to be transmitted. The channel matrix $\mathbf{H}$ is introduced in the next section.

RecAnt-SSK constitutes a special case of RecAnt-SM, where the information bits are encoded only into the RPs. In this case, the signal model simplifies as follows:

$$
\mathbf{y} = \sqrt{\rho} \mathbf{He}_p + \mathbf{n}
$$

(2)

Based on the signal model in (1), the maximum likelihood (ML-) optimum demodulator, by assuming full CSI available at the receiver, can be formulated as
follows [2]:

\[
\left( q, x_n \right) = \arg \max_{q=1, \ldots, P \text{ and } n=1, \ldots, M} \{ D(q, x_n) \}
\]  

(3)

where:

\[
D(q, x_n) = \sum_{n_r=1}^{N_r} \left[ y_{n_r}^* (H_{n_r, q} x_n) - \frac{1}{2} |H_{n_r, q} x_n|^2 \right]
\]  

(4)

where \( y_{n_r} \) is the \( n_r \)-th entry of \( y \) and \( H_{n_r, q} \) the entry in the row \( n_r \) and column \( q \) of \( H \). The demodulator of RectAnt-SSK can be obtained in a similar way.

2.2 Channel Model

In this section, we introduce the channel model \( H \) that we briefly mentioned in the previous section. As far as RectAnt-SM is concerned, the channel model plays an
### Table 1: Distribution of variables for the considered channel model.

| Variable | Distribution | PDF | Range |
|----------|--------------|-----|-------|
| $\beta_k$ | Gaussian | $\text{CN}(0,1)$ | $(-\infty,\infty)$ |
| $\theta_k$ | Truncated Laplacian ([22]) | $f_{\theta}(\theta) = C_L \exp \left( -\frac{\sqrt{2}\theta - \theta_0}{\sigma_L} \right) \sin(\theta)$, $C_L = \frac{2}{\sqrt{8\pi} L \sigma_L} \exp \left( -\frac{\theta_0}{\sqrt{2} \sigma_L} \right) \cosh \left( \sqrt{\frac{2}{2}} \frac{\theta_0}{\sigma_L} \right)$ | $(0,\pi]$ |
| $\phi_k$ | Von-Mises ([22]) | $f_{\phi}(\phi) = \frac{\kappa}{2\pi I_0(\kappa)} \exp(\kappa \cos(\phi - \mu))$ | $(-\pi,\pi]$ |
| $\phi_k$ | Truncated Gaussian [23] | $f_{\phi}(\phi) = C_G \exp \left( -\left( \frac{\phi - \phi_0}{\sqrt{2}\sigma_G} \right)^2 \right)$, $C_G = \frac{1}{\sqrt{2\pi\sigma_G} \Phi(\phi)}$, $\Phi(x) = \frac{1}{2} \left( 1 + \text{erf}(x/\sqrt{2}) \right)$ | $(-\pi,\pi]$ |
| $\phi_k$ | Uniform [23] | $f_{\phi}(\phi) = \begin{cases} \frac{1}{b-a} & \text{for } a \leq \phi \leq b, \\ 0 & \text{otherwise} \end{cases}$ | | 

important role, since the combined effect of RP and channel determines the system performance. Since we consider three-dimensional RPs (see Fig. 1), the considered channel model is chosen appropriately. More precisely, the channel model is based on a ray-based and cluster approach similar to [21]. A sketched representation of the channel model is given in Fig. 2.

For simplicity and without loss of generality, we consider a channel model with a single cluster and with multiple rays. The number of rays is denoted by $K$. The $N_r \times P$ channel matrix, which accounts for the RPs of the reconfigurable antenna as well, can be formulated as follows:

$$H = \frac{1}{\sqrt{K}} \sum_{k=1}^{K} \beta_k \mathbf{a}^r (\theta_k^t, \phi_k^t) (\mathbf{a}^t (\theta_k^r, \phi_k^r))^T$$

(5)

where the normalization factor $1/\sqrt{K}$ preserves the average unit energy of the channel, and the following notation is used:

- $\beta_k$ is the fading coefficient of the $k$th ray;
- $\mathbf{a}^r$ is the $N_r \times 1$ array response vector of the receiver;
- $\mathbf{a}^t$ is the $N_t \times 1$ array response vector of the transmitter;
- $(\theta_k^t, \phi_k^t)$ are the azimuth and elevation angles of departure (AoD) of the $k$th ray;
- $(\theta_k^r, \phi_k^r)$ are the azimuth and elevation angles of arrival (AoA) of the $k$th ray.

As far as the statistical distributions of $\beta_k$, $\theta_k$, and $\phi_k$ as concerned, Table 1 summarizes the most commonly used models. In particular, $\theta_k$ is often modeled as a truncated Laplacian random variable, and $\phi_k$ is often modeled as a Von-Mises, truncated Gaussian, or an uniform random variable. For each ray, the random variables are assumed to be independent and identically distributed.

The specific characteristics of the receiver and transmitter are determined by $\mathbf{a}^r$ and $\mathbf{a}^t$, respectively. As far as the receiver is concerned, we consider, as an example, a uniform linear array with an omni-directional RP of unit gain. As far as the transmitter is concerned, we consider a reconfigurable antenna with $P$ different RPs. The RPs are denoted as follows:

$$G_p(\theta, \phi) = \sqrt{G_p(\theta, \phi) \exp(j\Omega_p(\theta, \phi))}$$

(6)
for \( p = 1, \ldots, P \), and \( G_p(\theta, \phi) \) and \( \Omega_p(\theta, \phi) \) are the amplitude and phase of the \( p \)th RP, respectively.

Based on these assumptions, \( \mathbf{H}_{n_r,p} \) can be formulated as follows:

\[
\mathbf{H}_{n_r,p} = \frac{1}{\sqrt{K}} \sum_{k=1}^{K} \beta_k \exp(j \| \mathbf{k} \| d(n_r - 1) \sin(\theta_k^p) \sin(\phi_k^p)) \times \sqrt{G_p(\theta_k^p, \phi_k^p) \exp(j\Omega_p(\theta_k^p, \phi_k^p))}
\]

(7)

where \( n_r = 1, \ldots, N_r, \ p = 1, \ldots, P, \ d \) is the distance between adjacent antennas, and \( \mathbf{k}(\theta, \phi) \) is the wavevector defined as follows:

\[
k(\theta, \phi) = \frac{2\pi}{\lambda} [\sin(\theta) \cos(\phi), \sin(\theta) \sin(\phi), \cos(\theta)]^T
\]

(8)

where \( \lambda \) is the wavelength.

### 3 Average Bit Error Probability

From [15], it is known that the average bit error probability (ABEP) of the system model under analysis can be formulated as follows:

\[
\text{ABEP} \leq \frac{1}{PM} \log_2(PM) \sum_{p=1}^{P} \sum_{m=1}^{M} \sum_{q=1}^{P} \sum_{n=1}^{M} N_H \text{APEP} \left( (p, x_m) \rightarrow (q, x_n) \right)
\]

(9)

where APEP denotes the average pairwise error probability, which is the probability of demodulating the RP \( q \) and the symbol \( x_n \) if the RP \( p \) and the symbol \( x_m \) have been transmitted, and are the only two possible options, and \( N_H \) denotes the number of bits that the latter two constellation points different from each other.

The pairwise error probability (PEP), \( \text{Pr}_E \), of deciding for the \( q \)th radiation pattern while the \( p \)th radiation pattern is transmitted and deciding for the symbol \( x_n \) while the symbol \( x_m \) is transmitted can be written as follows:

\[
\text{Pr}_E \left( (p, x_m) \rightarrow (q, x_n) \mid \mathbf{H} \right) = \text{Pr} \left( D(p, x_m) < D(q, x_n) \right)
\]

\[
= Q \left( \sqrt{\frac{p}{2} \gamma_{p,q,x_m,x_n}(\mathbf{H})} \right)
\]

(10)

where:

\[
\gamma_{p,q,x_m,x_n}(\mathbf{H}) = \sum_{n_r=1}^{N_r} |\mathbf{H}_{n_r,q,x_n} - \mathbf{H}_{n_r,p,x_m}|^2
\]

(11)
As a result, the APEP can be written as follows:

\[
\text{APEP} ((p, x_m) \rightarrow (q, x_n)) = \mathbb{E}_H \left\{ Q \left( \sqrt{\frac{\rho}{2}} \gamma_{p,q,x_m,x_n}(H) \right) \right\} \\
= (a) \mathbb{E}_H \left\{ \frac{1}{\pi} \int_{0}^{\pi/2} \exp \left( -\frac{\rho \gamma_{p,q,x_m,x_n}}{4\sin^2(\vartheta)} \right) d\vartheta \right\} \\
= (b) \frac{1}{\pi} \int_{0}^{\pi/2} M_{\gamma_{p,q,x_m,x_n}} \left( \frac{-\rho}{4\sin^2(\vartheta)} \right) d\vartheta
\]  

(12)

where (a) and (b) follow by applying the Craig’s formula [15] and from the definition of MGF of \( \gamma_{p,q,x_m,x_n} \), respectively.

3.1 Setup with \( N_r = 1 \)

We start by considering the system setup with \( N_r = 1 \). The APEP is formulated in the following proposition.

**Proposition 1** Let \( \zeta(K, \vartheta) = \frac{\rho}{4K \sin^2(\vartheta)} \). If \( N_r = 1 \), the APEP of RecAnt-SM is as follows:

\[
\text{APEP} = \frac{1}{\pi} \int_{0}^{\pi/2} \int_{0}^{\infty} \exp(-z) \left( \int_{0}^{\pi} \int_{-\pi}^{\pi} \exp \left( -z \zeta(K, \vartheta) \psi(p, q, x_m, x_n, \theta^t, \phi^t) \right) f_\theta(\theta^t)f_\phi(\phi^t) d\theta d\phi \right)^K dz d\vartheta
\]

(13)

where:

\[
\psi(p, q, x_m, x_n, \theta^t, \phi^t) = \left| \sqrt{G_q(\theta^t, \phi^t) \exp(j\Omega_q(\theta^t, \phi^t))x_n} - \sqrt{G_p(\theta^t, \phi^t) \exp(j\Omega_p(\theta^t, \phi^t))x_m} \right|^2
\]

(14)

**Proof** See the Appendix.

In the high-SNR regime, the APEP is given in the following proposition.

**Proposition 2** If \( N_r = 1 \), the APEP of RecAnt-SM in the high-SNR regime is as follows:

\[
\text{APEP} \leq \frac{1}{\rho} \int_{0}^{\infty} \left( \int_{0}^{\pi} \int_{-\pi}^{\pi} \exp \left( -z \frac{1}{K} \psi(p, q, x_m, x_n, \theta^t, \phi^t) \right) f_\theta(\theta^t)f_\phi(\phi^t) d\theta d\phi \right)^K dz
\]

(15)

where \( \psi \) is defined in (14).

**Proof** See the Appendix.

Equations (13) and (15) provide one with accurate performance predictions of the APEP. The analytical expression is, however, quite complex due to the discrete
number of rays that are considered in the system model. In the following two propositions, we provide an asymptotic expression of the APEP under the assumption $K \to \infty$. In the sequel, we will show that the simplified analytical expression of the APEP is accurate even for moderate values of $K$.

**Proposition 3** Assume $K \to \infty$ and $N_r = 1$. The APEP can be simplified as follows:

$$\text{APEP} \leq \frac{1}{2} \left( 1 - \sqrt{\frac{\rho \Theta}{\rho \Theta + 4}} \right)$$

(16)

where

$$\Theta = \int_0^\pi \int_{-\pi}^\pi \psi \left( p, q, x_m, x_n, \theta^t, \phi^t \right) f_\theta(\theta^t) f_\phi(\phi^t) d\theta^t d\phi^t$$

(17)

where $\psi$ is defined in (14).

**Proof** See the Appendix.

**Proposition 4** Assume $K \to \infty$ and $N_r = 1$. The APEP in the high-SNR regime can be simplified as follows:

$$\text{APEP} \leq \frac{1}{\rho \Theta}$$

(18)

where $\Theta$ is defined in (17).

**Proof** See the Appendix.

By direct inspection of the obtained expression of the APEP, we evince that the error probability is minimized as $\Theta$ increases. As expected, therefore, we evince that the error probability decreases as the difference between the RPs increases. It is worth mentioning, however, that the difference between the RPs is weighted by the distribution of the AoD of the rays. Thus, the APEP depends on both the RPs themselves and the specific characteristics of the channel.

### 3.2 Setup with $N_r = 2$

In this section, we study the system setup where two antennas are available at the receiver. The following proposition generalizes Proposition 3.

**Proposition 5** Assume $K \to \infty$ and $N_r = 2$. The APEP in the high-SNR regime can be formulated as follows:

$$\text{APEP} \leq \frac{3}{\rho^2 \left( \int_{-\pi}^\pi \int_0^\pi \psi \left( p, q, x_m, x_n, \theta^t, \phi^t \right) f_\theta(\theta^t) f_\phi(\phi^t) d\theta^t d\phi^t \right)^2 \Psi}$$

$$\Psi = 1 - \left( \int_{-\pi}^\pi \int_0^\pi \cos \left( \|k\| d \left( \sin (\theta^r) \sin (\phi^r) \right) \right) f_\theta(\theta^r) f_\phi(\phi^r) d\theta^r d\phi^r \right)^2 - \left( \int_{-\pi}^\pi \int_0^\pi \sin \left( \|k\| d \left( \sin (\theta^r) \sin (\phi^r) \right) \right) f_\theta(\theta^r) f_\phi(\phi^r) d\theta^r d\phi^r \right)^2$$

(19)
where $\psi$ is defined in (14).

By direct inspection of the obtained APEP, we evince that the diversity order is equal to two if two antennas are available at the receiver. This is consistent with conventional SM [15].

3.3 Setup with generic $N_r$

In this section, we generalize the previous analytical frameworks for $N_r = 1$ and $N_r = 2$, by considering a generic value of $N_r$.

**Theorem 1** Assume $K \to \infty$. The APEP in the high-SNR regime can be formulated as follows:

$$\text{APEP} \leq \frac{\alpha_{N_r}}{\rho^{N_r}[\psi(p, q, x_m, x_n, \theta^t, \phi^t)]^{N_r} \mathbb{E}_{\theta^r, \phi^r} \{F(\theta^{1,r}, \ldots, \theta^{N_r,r}, \phi^{1,r}, \ldots, \phi^{N_r,r})\}}$$

$$\alpha_{N_r} = \frac{1}{2} \left( \frac{2N_r}{N_r} \right) + \sum_{k=0}^{N_r-1} (-1)^{N_r-k} \frac{2N_r}{k} \sin \left( \frac{\pi (N_r - k)}{2} \right)$$

where $\psi$ is defined in (14).

**Proof** See the Appendix.

By direct inspection of the obtained APEP, we observe that the diversity order is equal to $N_r$, as in conventional SM [15].

The main limitation of (20) is that $\mathbb{E}_{\theta^r, \phi^r} \{F(\theta^{1,r}, \ldots, \theta^{N_r,r}, \phi^{1,r}, \ldots, \phi^{N_r,r})\}$ is not analytically tractable and cannot, in general, be formulated in closed-form. In some special cases, however, this is possible. Notably if $N_r = 3$, as reported in the following proposition.

**Proposition 6** Assume $K \to \infty$ and $N_r = 3$. The APEP in the high-SNR regime can be formulated as follows:

$$\text{APEP} \leq \frac{10}{\rho^3[\psi(p, q, x_m, x_n, \theta^t, \phi^t)]^3 \mathbb{E}_{\theta^r, \phi^r} \{F(\theta^{1,r}, \theta^{2,r}, \theta^{3,r}, \phi^{1,r}, \phi^{2,r}, \phi^{3,r})\}}$$

where the following definition holds true:

$$\mathbb{E}_{\theta^r, \phi^r} \{F(\theta^{1,r}, \theta^{2,r}, \theta^{3,r}, \phi^{1,r}, \phi^{2,r}, \phi^{3,r})\} = 1 + 2(E_1)^2 E_3 - 2(E_2)^2 E_3 + 4E_1 E_2 E_4 - (E_3)^2 - (E_4)^2 - 2(E_1)^2 - 2(E_2)^2$$

(22)
Proof See the Appendix.

4 Antenna Prototype with Reconfigurable Radiation Patterns

In order to test the performance of RectAnt-SM and to assess its practical feasibility, we have designed and fabricated a reconfigurable antenna that yields multiple radiation patterns. A photo of the antenna prototype specifically designed to implement RectAnt-SM is given in Fig. 3. The proposed antenna needs a single radio frequency chain, and is capable of generating 8 RPs. Four or them are illustrated in Fig. 1. The 8 different RPs are obtained by considering a $4 \times 4$ array, as illustrated in Fig. 4, and by using a different excitation matrix. Five excitation matrices are
Each entry of the $4 \times 4$ matrix represents the excitation that is fed into the corresponding antenna of the array. The excitation has unit amplitude and its phase is either 0 or 180, which is denoted by the sign “+” and “-”, respectively, in the excitation matrices.

The designed prototype has been studied and optimized by simulating the $4 \times 4$ antenna array with the full-wave solver Ansys HFSS. Based on the optimized design, a prototype antenna has been fabricated and its RPs have been measured in an anechoic chamber, as illustrated in Fig. 5. In Fig. 6, we report, as an example, the simulated and measured RP $RP_1$ that is reported in Fig. 1 as well.

5 Numerical Results and Discussion

In this section, we provide some numerical results in order to validate the analytical derivation of the bit error probability, and in order to assess the achievable performance by using the RPs that are obtained from the fabricated antenna prototype. We show, in particular, that by appropriately selecting the RPs that minimize the analytical framework of the error probability, the error probability can be greatly decreased.
In Fig. 7, we compare Monte Carlo simulations against the proposed analytical framework of the bit error probability. In Fig. 8, we study the impact of $K$ on the error probability with the aim of assessing the accuracy of the asymptotic framework for $K \to \infty$. Both figures confirm that our analytical frameworks are accurate, and in agreement with Monte Carlo simulations.

In Figs. 9, 10, and 11, we report the bit error probability as a function of the number of antennas at the receiver. We observe the good accuracy of the proposed analytical frameworks, and, we note, in particular, that RectAnt-SM provides one with a diversity order equal to the number of antennas at the receiver.

In Fig. 12, we report the APEP as a function of the RPs. In particular, with the aid of the analytical framework of the error probability, we compute the ABEP for all possible combinations of four out of eight RPs in order to identify the impact of the RPs on the error performance. We observe that an appropriate choice of the RPs can yield a significant performance gain. The reason is that, due to practical design constraints, it may not be possible to design several RPs that are very different from
Figure 6: Comparison of simulated (Sim) and measured (Meas) RP $R_{P1}$. The beam cuts are measured at differently oriented angles (0 and 90 degrees) in space. “Co” stands for “Copolar gain” and “XP” stands for “Cross Polar gain”.

Figure 7: ABEP of RecAnt-SM ($P = 2$, $N_r = 1$, $M = 2$ (BPSK)). The results are obtained by using $R_{P1}$ and $R_{P2}$.

each other. Therefore, identifying the best of them that provide good performance as a function of the channel model is an important optimization problem. The proposed analytical framework allows us to solve this optimization problem at a low complexity and high efficiency.
Figure 8: ABEP of RecAnt-SM ($P = 2$, $N_r = 1$, $M = 2$ (BPSK)), as a function of $K$. The results are obtained by using RP$_1$ and RP$_2$.

Figure 9: ABEP of RecAnt-SM ($P = 2$, $N_r = 1, 2, 3$, $M = 2$ (BPSK)). The results are obtained by using RP$_1$ and RP$_2$.

6 Conclusion
In this paper, we have studied the performance of spatial modulation based on reconfigurable antennas. We have introduced an analytical framework to compute the error probability, and have described the prototype of a reconfigurable antenna that is specifically designed for application to spatial modulation. By using the radiation patterns obtained from the manufactured antenna prototype, we have
shown that spatial modulation based on reconfigurable antennas works in practice, and that its performance can be optimized by appropriately choosing the radiation patterns that minimize the proposed analytical framework of the error probability.
7 Appendix

7.1 Proof of Proposition 1 and Proposition 2

7.1.1 Proof of Proposition 1

Let $\nu_{nr} = H_{nr, q} x_n - H_{nr, p} x_m$ for $n_r = 1, \ldots, N_r$. Recall that $N_r = 1$. We note that $\nu_1$ is a zero mean complex Gaussian variable with variance:

$$\sigma_{\nu_1}^2 = \frac{1}{K} \sum_{k=1}^K \left| G_q(\theta_k, \phi_k) \exp(j\Omega_q(\theta_k, \phi_k)) x_n - G_p(\theta_k, \phi_k) \exp(j\Omega_p(\theta_k, \phi_k)) x_m \right|^2$$

(28)

Thus, $\gamma_{p,q,x_m,x_n} = | \nu_1 |^2$ is an exponential random variable whose probability density function is:

$$f_x(x; \lambda) = \lambda \exp(-\lambda x), \ x \geq 0$$

with $\lambda = 1/\sigma_{\nu_1}^2$.

The APEP can then be formulated as follows:

$$\text{APEP} = \frac{1}{\pi} \int_0^{\pi/2} E_{\sigma_{\nu_1}^2} \left\{ \left( 1 + \frac{\rho \sigma_{\nu_1}^2}{4 \sin^2(\theta)} \right)^{-1} \right\} d\theta$$

(29)

We note that $\sigma_{\nu_1}^2$ is a random variable that depend on $\{\theta_k, \phi_k\}_{k=1}^K$. The expectation can be computed by using the approach introduced in [24], as follows:

$$\text{APEP} = \frac{1}{\pi} \int_0^{\pi/2} \left( \int_0^\infty M_S(z) \, dz \right) d\theta$$

(30)
where $S = 1 + \frac{\rho \sigma^2_{\nu_1}}{4 \sin^2(\vartheta)}$, and:

$$M_S(z) = \exp(-z)M_{\sigma^2_{\nu_1}} \left( z \frac{\rho}{4 \sin^2(\vartheta)} \right)$$  \hspace{1cm} (31)

With the aid of some algebraic manipulations, we obtain the following:

$$M_{\sigma^2_{\nu_1}} \left( z \frac{\rho}{4 \sin^2(\vartheta)} \right) = \mathbb{E}_{\theta^k, \phi^k} \left\{ \exp \left( -z \frac{\rho}{4 K \sin^2(\vartheta)} \sum_{k=1}^{K} \psi(p, q, x_m, x_n, \theta^l_k, \phi^l_k) \right) \right\}$$

$$= \mathbb{E}_{\theta^k, \phi^k} \left\{ \prod_{k=1}^{K} \exp \left( -z \frac{\rho}{4 K \sin^2(\vartheta)} \psi(p, q, x_m, x_n, \theta^l_k, \phi^l_k) \right) \right\}$$

$$= \prod_{k=1}^{K} \left( \int_{-\pi}^{\pi} \int_{0}^{\pi/2} \exp \left( -z \frac{\rho}{4 K \sin^2(\vartheta)} \psi(p, q, x_m, x_n, \theta^l_k, \phi^l_k) \right) f_\theta(\theta^l_k) f_\phi(\phi^l_k) d\theta^l_k d\phi^l_k \right)$$  \hspace{1cm} (32)

where:

$$\psi(p, q, x_m, x_n, \theta^l_k, \phi^l_k) = \frac{\sqrt{G_q(\theta^l_k, \phi^l_k)} \exp(j \Omega_q(\theta^l_k, \phi^l_k)) x_n - \sqrt{G_p(\theta^l_k, \phi^l_k)} \exp(j \Omega_p(\theta^l_k, \phi^l_k)) x_m}{2}$$

The proof follows from the following identity:

$$\int_{-\pi}^{\pi} \int_{0}^{\pi/2} f_\theta(\theta^l) f_\phi(\phi^l) d\theta^l d\phi^l = \int_{-\pi}^{\pi} f_\theta(\theta^l) d\theta^l \int_{0}^{\pi/2} f_\phi(\phi^l) d\phi^l = 1  \hspace{1cm} (33)$$

### 7.1.2 Proof of Proposition 2

From (29), we obtain, in the high-SNR regime, the following:

$$\text{APEP}_{p, q} = \mathbb{E}_{\sigma^2_{\nu_1}} \left\{ \frac{1}{\pi} \int_{0}^{\pi/2} \left( 1 + \frac{\rho \sigma^2_{\nu_1}}{4 \sin^2(\vartheta)} \right)^{-1} d\vartheta \right\}$$

$$\rho \gg 1 \leq \mathbb{E}_{\sigma^2_{\nu_1}} \left\{ \frac{1}{\pi} \int_{0}^{\pi/2} \left( \frac{\rho \sigma^2_{\nu_1}}{4 \sin^2(\vartheta)} \right)^{-1} d\vartheta \right\}$$

$$= \frac{1}{\rho} \mathbb{E}_{\sigma^2_{\nu_1}} \left\{ \frac{1}{\sigma^2_{\nu_1}} \int_{0}^{\pi/2} \left( \frac{1}{4 \sin^2(\vartheta)} \right)^{-1} d\vartheta \right\}$$

$$= \frac{1}{\rho} \mathbb{E}_{\sigma^2_{\nu_1}} \left\{ \frac{1}{\sigma^2_{\nu_1}} \right\}  \hspace{1cm} (34)$$

The rest of the proof follows by using similar steps as for the proof of Proposition 1.
7.2 Proof of Proposition 3 and Proposition 4

7.2.1 Proof of Proposition 3

By using the Maclaurin series expansion and keeping the first two dominant terms, we have the following:

\[
\exp\left(-z\tilde{\zeta}(K, \vartheta)\psi\left(p, q, x_m, x_n, \theta^t, \phi^t\right)\right) = 1 - z\tilde{\zeta}(K, \vartheta)\psi\left(p, q, x_m, x_n, \theta^t, \phi^t\right) + \mathcal{O}\left(z\tilde{\zeta}(K, \vartheta)\psi\left(p, q, x_m, x_n, \theta^t, \phi^t\right)\right)
\]

\[
\approx 1 - z\tilde{\zeta}(K, \vartheta)\psi\left(p, q, x_m, x_n, \theta^t, \phi^t\right)
\]

(35)

By using this approximation, we have the following:

\[
\int_{0}^{\pi} \int_{-\pi}^{\pi} \exp\left(-z\tilde{\zeta}(K, \vartheta)\psi\left(p, q, x_m, x_n, \theta^t, \phi^t\right)\right) f_\theta(\theta^t) f_\phi(\phi^t) d\theta d\phi \\
\approx \int_{0}^{\pi} \int_{-\pi}^{\pi} \left(1 - z\tilde{\zeta}(K, \vartheta)\psi\left(p, q, x_m, x_n, \theta^t, \phi^t\right)\right) f_\theta(\theta^t) f_\phi(\phi^t) d\theta d\phi \\
= 1 - z\tilde{\zeta}(K, \vartheta) \int_{-\pi}^{\pi} \psi\left(p, q, x_m, x_n, \theta^t, \phi^t\right) f_\theta(\theta^t) f_\phi(\phi^t) d\theta d\phi
\]

(36)

Let us consider the following integral:

\[
\Theta = \int_{0}^{\pi} \int_{-\pi}^{\pi} \psi\left(p, q, x_m, x_n, \theta^t, \phi^t\right) f_\theta(\theta^t) f_\phi(\phi^t) d\theta d\phi
\]

(37)

In addition, the following holds true:

\[
\lim_{K \to +\infty} \left(1 - \frac{z}{4\sin^2(\vartheta)} \Theta K\right) = \exp\left(-z\frac{\rho}{4\sin^2(\vartheta)} \Theta\right)
\]

(38)

where we used the following notable limit:

\[
\lim_{x \to +\infty} \left(1 + \frac{k}{x}\right)^x = e^k
\]

(39)

Therefore, the asymptotic APEP is:

\[
\text{APEP} \leq \frac{1}{\pi} \int_{0}^{\pi/2} \int_{0}^{\infty} \exp\left(-z\left(1 + \frac{\rho}{4\sin^2(\vartheta)} \Theta\right)\right) dz d\vartheta
\]

\[
= \left(\frac{a}{b}\right) \int_{0}^{\pi/2} \left(1 + \frac{\rho}{4\sin^2(\vartheta) \Theta}\right)^{-1} d\vartheta
\]

\[
= \left(\frac{a}{b}\right) \left(1 - \sqrt{\frac{\rho \Theta}{\rho \Theta + 1}}\right)
\]

(40)

where the first equality (a) comes the fact that \(\int_{0}^{\infty} \exp(-zc) = \frac{1}{c}, c > 0\) and the second equality (b) follows from (5A.4a) in [25]. This concludes the proof.
7.2.2 Proof of Proposition 4

By using steps similar to Proposition 3, the asymptotic APEP can be written as follows:

\[
\text{APEP} \leq \frac{1}{\pi} \int_0^{\pi/2} \left(1 + \frac{\rho}{4 \sin^2(\vartheta)} \Theta \right)^{-1} d\vartheta
\]

\[
\rho \gg 1 \leq \frac{1}{\rho \Theta} \left( \frac{1}{\pi} \int_0^{\pi/2} \left( \frac{1}{4 \sin^2(\vartheta)} \right)^{-1} d\vartheta \right),
\]

which concludes the proof.

7.3 Proof of Proposition 5

We first introduce the following lemma [27] for application to hermitian quadratic forms in complex normal variables.

**Lemma 1** Let \( v_n (n = 1, \ldots, N) \) be a set of complex Gaussian random variables having zero mean. Let \( \kappa \), with \( v = [v_1, \ldots, v_N]^T \), be an Hermitian quadratic form:

\[
\kappa = v^H I_N v
\]

Its MGF is as follows:

\[
M_{\kappa}(s) = \prod_{n=1}^{N} (1 - s \lambda_n)^{-1}
\]

where \( \lambda_n \) is the \( n \)th eigenvalue of the covariance matrix \( R_v = \mathbb{E}\{vv^H\} \).

**Proof** See [27].

The proof of Proposition 5 can be split in three steps.

**Step 1**: By using Lemma 1 with \( N = N_r = 2 \), we have:

\[
\text{APEP} \approx \frac{1}{\rho^2} \mathbb{E}\{\nu_1 \nu_1^*\} \mathbb{E}\{\nu_2 \nu_2^*\} \left\{ \left( \frac{3}{\lambda_1 \lambda_2} \right) \right\}
\]

where \( \lambda_1 \) and \( \lambda_2 \) are eigenvectors of the covariance matrix:

\[
R = \begin{bmatrix}
\mathbb{E}\{\nu_1 \nu_1^*\} & \mathbb{E}\{\nu_1 \nu_2^*\} \\
\mathbb{E}\{\nu_2 \nu_1^*\} & \mathbb{E}\{\nu_2 \nu_2^*\}
\end{bmatrix}
\]

and \( R \) is assumed to be full rank.
It is worth mentioning that $\lambda_1$ and $\lambda_2$ depend on the random variables $\theta_{tk}$, $\phi_{tk}$, $\theta_{rk}$, $\phi_{rk}$. In particular, from Lemma 1, we have:

\[
\text{APEP} = \mathbb{E}_{\theta_{tk}, \phi_{tk}, \theta_{rk}, \phi_{rk}} \left\{ \frac{1}{\pi} \int_0^{\pi/2} \prod_{n_r=1}^2 (1 + \frac{\rho}{4\sin^2(\vartheta)} \lambda_{nr})^{-1} d\vartheta \right\} \tag{46}
\]

Also, we have the following:

\[
\frac{1}{\left(1 + \frac{\rho}{4\sin^2(\vartheta)} \lambda_1\right) \left(1 + \frac{\rho}{4\sin^2(\vartheta)} \lambda_2\right)} = \frac{A_1}{\left(1 + \frac{\rho}{4\sin^2(\vartheta)} \lambda_1\right)} + \frac{A_2}{\left(1 + \frac{\rho}{4\sin^2(\vartheta)} \lambda_2\right)} \tag{47}
\]

which yields:

\[
A_1 = \frac{\lambda_1}{\lambda_1 - \lambda_2}, \quad A_2 = -\frac{\lambda_2}{\lambda_1 - \lambda_2} \tag{48}
\]

For high-SNR, we have:

\[
\left(1 + \frac{\rho}{4\sin^2(\vartheta)} \lambda_{nr}\right)^{-1} \approx \left(\frac{\rho}{4\sin^2(\vartheta)} \lambda_{nr}\right)^{-1} - \left(\frac{\rho}{4\sin^2(\vartheta)} \lambda_{nr}\right)^{-2} \tag{49}
\]

where we have used the second-order Taylor approximation.

Thus, by substituting (48) and (49) in (46), we obtain:

\[
\text{APEP} = \mathbb{E}_{\theta_{tk}, \phi_{tk}, \theta_{rk}, \phi_{rk}} \left\{ \sum_{i=1}^2 A_i \left\{ \frac{1}{\pi} \int_0^{\pi/2} \left(\frac{\rho}{4\sin^2(\vartheta)} \lambda_{i}\right)^{-1} d\vartheta - \frac{1}{\pi} \int_0^{\pi/2} \left(\frac{\rho}{4\sin^2(\vartheta)} \lambda_{i}\right)^{-2} d\vartheta \right\} \right\}
\]

\[
= \mathbb{E}_{\theta_{tk}, \phi_{tk}, \theta_{rk}, \phi_{rk}} \left\{ \frac{1}{\rho} \frac{1}{\lambda_1 \pi} \int_0^{\pi/2} \left(\frac{1}{4\sin^2(\vartheta)}\right)^{-1} d\omega - \frac{1}{\rho} \frac{1}{\lambda_2 \pi} \int_0^{\pi/2} \left(\frac{1}{4\sin^2(\vartheta)}\right)^{-2} d\omega \right\}
\]

\[
\overset{(a)}{=} \mathbb{E}_{\theta_{tk}, \phi_{tk}, \theta_{rk}, \phi_{rk}} \left\{ \frac{1}{\rho} \left(\frac{\lambda_1}{\lambda_1 - \lambda_2} \left[\frac{1}{\lambda_1} - 3\frac{\rho \lambda^2_1}{\lambda_1} \right] - \frac{\lambda_2}{\lambda_2 - \lambda_2} \left[\frac{1}{\lambda_2} - 3\frac{\rho \lambda^2_2}{\lambda_2} \right] \right) \right\}
\]

\[
= \mathbb{E}_{\theta_{tk}, \phi_{tk}, \theta_{rk}, \phi_{rk}} \left\{ \frac{1}{\rho^2} \left(\frac{3}{\lambda_1 \lambda_2} \right) \right\} \tag{50}
\]

where (a) follows from:

\[
\frac{1}{\pi} \int_0^{\pi/2} \left(\frac{1}{4\sin^2(\omega)}\right)^{-1} d\omega = 1, \quad \frac{1}{\pi} \int_0^{\pi/2} \left(\frac{1}{4\sin^2(\omega)}\right)^{-2} d\omega = 3 \tag{51}
\]

**Step 2:** We compute the explicit expression of the product $\lambda_1 \lambda_2$. To this end, we introduce the following lemma.
Lemma 2  Assume that $\mathbf{R}$, defined in (45), is full rank and has two distinct eigenvalues $\lambda_1$ and $\lambda_2$. The product of the two eigenvectors $\lambda_1$ and $\lambda_2$ is as follows:

$$
\lambda_1 \lambda_2 = \mathbb{E}_{\theta^t, \phi^t, \theta^{t'}, \phi^{t'}} \left( \frac{1}{K^2} \left[ \sum_{k=1}^{K} \sum_{k'=1}^{K} \chi (\theta_k^t, \phi_k^t) \chi (\theta_{k'}^t, \phi_{k'}^t) \Upsilon \right] \right) 
$$

(52)

where

$$
\chi (\theta_k^t, \phi_k^t) = \sqrt{G_q (\theta_k^t, \phi_k^t) \exp (j \Omega_q (\theta_k^t, \phi_k^t))} - \sqrt{G_p (\theta_k^t, \phi_k^t) \exp (j \Omega_p (\theta_k^t, \phi_k^t))} 
$$

(53)

and

$$
\Upsilon = 1 - \cos (\|k\| d (\sin (\theta_r^k) \sin (\phi_r^k) - \sin (\theta_{r'}^k) \sin (\phi_{r'}^k))) 
$$

(54)

Proof By definition:

$$
\nu_1 = \frac{1}{\sqrt{K}} \sum_{k=1}^{K} \beta_k \chi (\theta_k^t, \phi_k^t) 
$$

(55)

$$
\nu_2 = \frac{1}{\sqrt{K}} \sum_{k=1}^{K} \beta_k \chi (\theta_k^t, \phi_k^t) \exp (j \|k\| d (\sin (\theta_r^k) \sin (\phi_r^k))) 
$$

(56)

Moreover, it is known that the product of the eigenvalues is equal to the determinant of the covariance matrix (i.e., $\det(\mathbf{R}) = \lambda_1 \lambda_2$). Thus, $\lambda_1 \lambda_2$ can be computed directly from $\det(\mathbf{R})$ as follows:

$$
\det (\mathbf{R}) = \mathbb{E} \{ \nu_1 \nu_1^{*} \} \mathbb{E} \{ \nu_2 \nu_2^{*} \} - \mathbb{E} \{ \nu_2 \nu_1 \} \mathbb{E} \{ \nu_1 \nu_2 \} 
$$

(57)

By substituting (55) and (56) into (57), we obtain (52) where we have used the identity:

$$
\frac{\exp (j \phi) + \exp (-j \phi)}{2} = \cos (\phi)
$$

and if $k = k'$ we have $1 - \exp (j \|k\| d (\sin (\theta_r^k) \sin (\phi_r^k) - \sin (\theta_{r'}^k) \sin (\phi_{r'}^k))) = 0$.

Step 3: We exploit the asymptotic analysis introduced in Proposition 3 to derive a closed-form expression of the APEP. We apply the following formula that is special case of (40) in [24] for $X = \lambda_1 \lambda_2$:

$$
\mathbb{E} (X^{-1}) = \int_0^{\infty} M_X (-z) \, dz 
$$

(58)

where $M_X (z) = \mathbb{E}_X \{ \exp (Xz) \}$. 
Then, we obtain:

$$
\mathbb{E}_X (\exp (Xz)) = \mathbb{E}_{\theta^t, \phi^t, \theta^r, \phi^r} \left( \prod_{k=1}^{K} \prod_{k'=1}^{K} \exp \left( \frac{1}{K^2} \chi (\theta^t_k, \phi^t_k) \chi (\theta^r_{k'}, \phi^r_{k'}) Yz \right) \right)
$$

$$
= \prod_{k=1}^{K} \prod_{k'=1}^{K} \left( \int_{-1}^{1} \int_{-1}^{1} \int_{-1}^{1} \int_{-1}^{1} \exp \left( \frac{1}{K^2} \chi (\theta^t_k, \phi^t_k) \chi (\theta^r_{k'}, \phi^r_{k'}) Yz \right) \phi^t_k \phi^r_{k'} f_{\theta^t_k} f_{\phi^t_k} f_{\theta^r_{k'}} f_{\phi^r_{k'}} d\theta^t_k d\phi^t_k d\theta^r_{k'} d\phi^r_{k'} \right)
$$

where the last equality follows from the assumption of independent and identically distributed random variables.

Moreover, by using the following approximation:

$$
\exp \left( \frac{1}{K^2} \chi (\theta^t, \phi^t) \chi (\theta^r, \phi^r) Yz \right) \approx 1 + \frac{1}{K^2} \chi (\theta^t, \phi^t) \chi (\theta^r, \phi^r) Yz
$$

in (59) and using the notable limit in (39), we obtain the following:

$$
\mathbb{E}_X (\exp (Xz)) \stackrel{K \to \infty}{\to} \exp \left( z \prod_{k=1}^{K} \prod_{k'=1}^{K} \int_{-1}^{1} \int_{-1}^{1} \int_{-1}^{1} \int_{-1}^{1} \chi (\theta^r_{k'}, \phi^r_{k'}) \phi^r_{k'} f_{\theta^r_{k'}} f_{\phi^r_{k'}} f_{\theta^r_{k'}} f_{\phi^r_{k'}} d\theta^r_{k'} d\phi^r_{k'} d\theta^r_{k'} d\phi^r_{k'} \right)
$$

Finally, substituting (61) in (58), and then (58) in (44), we conclude the proof by using the following result:

$$
\int_{-1}^{1} \int_{-1}^{1} \int_{-1}^{1} \int_{-1}^{1} \left( 1 - \cos (|k| d (\sin (\theta^r) \sin (\phi^r) - \sin (\theta^r) \sin (\phi^r))) \right) f_{\theta^r} f_{\phi^r} f_{\theta^r} f_{\phi^r} f_{\theta^r} f_{\phi^r} f_{\theta^r} f_{\phi^r} d\theta^r d\phi^r d\theta^r d\phi^r d\theta^r d\phi^r d\theta^r d\phi^r d\theta^r d\phi^r =
$$

$$
1 - \left( \int_{-1}^{1} \int_{-1}^{1} \cos (|k| d (\sin (\theta^r) \sin (\phi^r))) f_{\theta^r} f_{\phi^r} f_{\theta^r} f_{\phi^r} d\theta^r d\phi^r \right)^2 - \left( \int_{-1}^{1} \int_{-1}^{1} \sin (|k| d (\sin (\theta^r) \sin (\phi^r))) f_{\theta^r} f_{\phi^r} d\theta^r d\phi^r \right)^2
$$

7.4 Proof of Theorem 1

The proof of Theorem 1 generalizes the steps of Proposition 5 as follows.

**Step 1:** From Lemma 1, we have:

$$
\text{AEP} = \mathbb{E}_{\theta^t_k, \phi^t_k, \theta^r_{k'}, \phi^r_{k'}} \left\{ \frac{1}{\pi} \int_{0}^{\pi/2} \prod_{n=1}^{N_r} \left( 1 + \frac{\rho}{4 \sin^2 (\theta)} \lambda_n \right)^{-1} d\theta \right\}
$$

Then, we need to identify the coefficients \( A_{n_r} \) so that the following is satisfied:

$$
\frac{1}{N_r} \prod_{n_r=1}^{N_r} \left( 1 + \frac{\rho}{4 \sin^2 (\theta)} \lambda_{n_r} \right) = \sum_{n_r=1}^{N_r} \left( 1 + \frac{\rho}{4 \sin^2 (\theta)} \lambda_{n_r} \right)
$$
To this end, we can exploit the general formula of partial fraction decomposition [26, p. 66-67]:

$$A_{n_r} = \frac{\lambda_{n_r} N_r - 1}{\prod_{n_r \neq l=1}^{N_r} (\lambda_{n_r} - \lambda_l)}$$  \hspace{1cm} (65)

for $l, n_r = 1, \ldots, N_r$.

Thus, we have:

$$\text{APEP} \approx E_{\theta_t, \phi_t, \theta_r, \phi_r} \left\{ \frac{1}{\pi} \int_0^{\pi/2} \sum_{n_r=1}^{N_r} A_{n_r} \left[ \sum_{n=1}^{N_r} (-1)^{m+1} \left( \frac{\rho}{4\sin^2(\vartheta)} \lambda_{n_r} \right)^{-m} \right] d\vartheta \right\}$$

$$= E_{\theta_t, \phi_t, \theta_r, \phi_r} \left\{ \sum_{n_r=1}^{N_r} A_{n_r} \left[ \sum_{n=1}^{N_r} (-1)^{m+1} \frac{1}{\pi} \int_0^{\pi/2} \left( \frac{\rho}{4\sin^2(\vartheta)} \lambda_{n_r} \right)^{-m} d\vartheta \right] \right\}$$

$$= E_{\theta_t, \phi_t, \theta_r, \phi_r} \left\{ \sum_{n_r=1}^{N_r} A_{n_r} \left[ \sum_{m=1}^{N_r} (-1)^{m+1} (\rho \lambda_{n_r})^{-m} \left( \frac{1}{\pi} \int_0^{\pi/2} \left( \frac{1}{4\sin^2(\vartheta)} \right)^{-m} d\vartheta \right) \right] \right\}$$  \hspace{1cm} (66)

In the high-SNR regime, we can use the $N_r$th-order Taylor approximation as follows:

$$\left(1 + \frac{\rho}{4\sin^2(\vartheta)} \lambda_{n_r}\right)^{-N_r} \approx \sum_{m=1}^{N_r} (-1)^{m+1} \left( \frac{\rho}{4\sin^2(\vartheta)} \lambda_{n_r} \right)^{-m} + O \left( (-1)^{N_r+1} \left( \frac{\rho}{4\sin^2(\vartheta)} \lambda_{n_r} \right)^{-(N_r+1)} \right)$$  \hspace{1cm} (67)

We note that the following holds true:

$$\frac{1}{\pi} \int_0^{\pi/2} \left( \frac{1}{4\sin^2(\vartheta)} \right)^{-m} d\vartheta = \frac{1}{2} \left( \begin{array}{c} 2m \\ m \end{array} \right) + \sum_{k=0}^{m-1} (-1)^{m-k} 2 \left( \begin{array}{c} 2m \\ k \end{array} \right) \sin \left( \frac{\pi (m-k)}{2(m-k)} \right)$$  \hspace{1cm} (68)

where we have used the following identity [26, p. 31, eq. (1320.1)]:

$$\sin^{2m}(\vartheta) = \frac{1}{2^{2m}} \left\{ \sum_{k=0}^{m-1} (-1)^{m-k} 2 \left( \begin{array}{c} 2m \\ k \end{array} \right) \cos(2(m-k)\vartheta) + \left( \begin{array}{c} 2m \\ m \end{array} \right) \right\}$$  \hspace{1cm} (69)

Let us define:

$$\alpha_m = \left( \frac{1}{\pi} \int_0^{\pi/2} \left( \frac{1}{4\sin^2(\vartheta)} \right)^{-m} d\vartheta \right)^{-1}$$  \hspace{1cm} (70)
Then, we have the following:

\[
\text{AEP} \approx E_{\theta^t, \phi^t, \theta^r, \phi^r} \left\{ \sum_{n_r=1}^{N_r} A_{n_r} \left[ \sum_{m=1}^{N_r} (-1)^{m+1} (\rho \lambda_{n_r})^{-m} \alpha_m \right] \right\}
\]

\[
= E_{\theta^t, \phi^t, \theta^r, \phi^r} \left\{ \sum_{n_r=1}^{N_r} A_{n_r} \left[ (-1)^{N_r+1} (\rho \lambda_{n_r})^{-N_r} \alpha_{N_r} \right] \right\}
\]

\[
= E_{\theta^t, \phi^t, \theta^r, \phi^r} \left\{ \sum_{n_r=1}^{N_r} A_{n_r} \left[ \sum_{m=1}^{N_r-1} (-1)^{m+1} (\rho \lambda_{n_r})^{-m} \alpha_m \right] \right\}
\]

By induction, the following can be proved:

\[
\sum_{n_r=1}^{N_r} A_{n_r} \left[ \sum_{m=1}^{N_r-1} (-1)^{m+1} (\rho \lambda_{n_r})^{-m} \alpha_m \right] = 0
\]

and

\[
\sum_{n_r=1}^{N_r} A_{n_r} (-1)^{N_r+1} (\rho \lambda_{n_r})^{-N_r} \alpha_{N_r} = \frac{\alpha_{N_r}}{\rho^{N_r}} \prod_{n=1}^{N_r} \lambda_n
\]

Step 2: Let \( X = \prod_{n_r=1}^{N_r} \lambda_{n_r} \). By using steps similar to those of Lemma 2, we obtain the following:

\[
\text{det} \left( R_{\varphi} \right) = \frac{1}{K^{N_r}} \left( \sum_{k_1=1}^{K} \ldots \sum_{k_{N_r}=1}^{K} \left[ \prod_{i=1}^{N_r} \chi \left( \theta_{k_1}, \phi_{k_1}^t \right) F \left( \theta_{k_1}^r, \ldots, \theta_{k_{N_r}}^r, \phi_{k_1}^t, \ldots, \phi_{k_{N_r}}^t \right) \right] \right)
\]

where \( F \left( \theta_{k_1}, \ldots, \theta_{k_{N_r}}^r, \phi_{k_1}^t, \ldots, \phi_{k_{N_r}}^t \right) \).

Step 3: The APEP is then the following:

\[
\mathbb{E}_{X} \{ \exp (X z) \}
\]

\[
= E_{\theta^t, \phi^t, \theta^r, \phi^r} \left\{ \exp \left( \frac{z}{K^{N_r}} \left[ \sum_{k_1=1}^{K} \ldots \sum_{k_{N_r}=1}^{K} \left[ \prod_{i=1}^{N_r} \chi \left( \theta_{k_1}, \phi_{k_1}^t \right) F \left( \theta_{k_1}^r, \ldots, \theta_{k_{N_r}}^r, \phi_{k_1}^t, \ldots, \phi_{k_{N_r}}^t \right) \right] \right] \right) \right\}
\]

\[
= E_{\theta^t, \phi^t, \theta^r, \phi^r} \left\{ \prod_{k_1=1}^{K} \ldots \prod_{k_{N_r}=1}^{K} \exp \left( \frac{z}{K^{N_r}} \left[ \prod_{i=1}^{N_r} \chi \left( \theta_{k_1}, \phi_{k_1}^t \right) F \left( \theta_{k_1}^r, \ldots, \theta_{k_{N_r}}^r, \phi_{k_1}^t, \ldots, \phi_{k_{N_r}}^t \right) \right] \right) \right\}
\]

\[
= \prod_{k_1=1}^{K} \ldots \prod_{k_{N_r}=1}^{K} \mathbb{E}_{\theta^t, \phi^t, \theta^r, \phi^r} \left\{ \exp \left( \frac{z}{K^{N_r}} \left[ \prod_{i=1}^{N_r} \chi \left( \theta_{k_1}, \phi_{k_1}^t \right) F \left( \theta_{k_1}^r, \ldots, \theta_{k_{N_r}}^r, \phi_{k_1}^t, \ldots, \phi_{k_{N_r}}^t \right) \right] \right) \right\}
\]

\[
= \left[ \mathbb{E}_{\theta^t, \phi^t, \theta^r, \phi^r} \left\{ \exp \left( \frac{z}{K^{N_r}} \left[ \prod_{i=1}^{N_r} \chi \left( \theta_{k_1}, \phi_{k_1}^t \right) F \left( \theta_{k_1}^r, \ldots, \theta_{k_{N_r}}^r, \phi_{k_1}^t, \ldots, \phi_{k_{N_r}}^t \right) \right] \right) \right\} \right]^{N_r}
\]
By using the following approximation:

\[
\exp\left(\frac{z}{K^N_r} \prod_{i=1}^{N_r} \chi \left(\theta^{i,t}, \phi^{i,t}\right) \right) F \left(\theta^{1,r}, \ldots, \theta^{N_r,r}, \phi^{1,r}, \ldots, \phi^{N_r,r}\right) \approx \left(76\right)
\]

we have:

\[
\mathbb{E} \left\{ \exp \left(X z \right) \right\} = \mathbb{E}_{\theta, \phi} \left\{ 1 + \frac{z}{K^N_r} \prod_{i=1}^{N_r} \chi \left(\theta^{i,t}, \phi^{i,t}\right) \right\} F \left(\theta^{1,r}, \ldots, \theta^{N_r,r}, \phi^{1,r}, \ldots, \phi^{N_r,r}\right) \approx \left(77\right)
\]

\[
\approx \exp \left( z \mathbb{E}_{\theta, \phi} \left\{ \prod_{i=1}^{N_r} \chi \left(\theta^{i,t}, \phi^{i,t}\right) \right\} F \left(\theta^{1,r}, \ldots, \theta^{N_r,r}, \phi^{1,r}, \ldots, \phi^{N_r,r}\right) \right) \approx \left(78\right)
\]

Thus, we obtain:

\[
\frac{\alpha_{N_r}}{\rho^{N_r}} \int_0^\infty M_X \left(-z\right) \, dz = \frac{\alpha_{N_r}}{\rho^{N_r}} \left[ \mathbb{E}_{\theta, \phi} \left\{ \prod_{i=1}^{N_r} \chi \left(\theta^{i,t}, \phi^{i,t}\right) \right\} \right] \mathbb{E}_{\theta, \phi} \left\{ F \left(\theta^{1,r}, \ldots, \theta^{N_r,r}, \phi^{1,r}, \ldots, \phi^{N_r,r}\right) \right\} \left(79\right)
\]

This concludes the proof.

7.5 Proof of Proposition 5
From Theorem 1, we can obtain (21). We need to prove how obtain the explicit form of the function \(F(\cdot)\). If \(N_r = 3\), the determinant of the covariance matrix \(R\) can be computed as follows:

\[
\text{det} \left( R \right) = \\
\mathbb{E} \left\{ \nu_1 \nu_1^* \right\} \mathbb{E} \left\{ \nu_2 \nu_2^* \right\} \mathbb{E} \left\{ \nu_3 \nu_3^* \right\} + \mathbb{E} \left\{ \nu_1 \nu_2^* \right\} \mathbb{E} \left\{ \nu_2 \nu_3^* \right\} \mathbb{E} \left\{ \nu_3 \nu_1^* \right\} + \mathbb{E} \left\{ \nu_1 \nu_3^* \right\} \mathbb{E} \left\{ \nu_2 \nu_1^* \right\} \mathbb{E} \left\{ \nu_3 \nu_2^* \right\} \\
- \mathbb{E} \left\{ \nu_1 \nu_3^* \right\} \mathbb{E} \left\{ \nu_2 \nu_2^* \right\} \mathbb{E} \left\{ \nu_3 \nu_1^* \right\} - \mathbb{E} \left\{ \nu_1 \nu_2^* \right\} \mathbb{E} \left\{ \nu_2 \nu_1^* \right\} \mathbb{E} \left\{ \nu_3 \nu_3^* \right\} - \mathbb{E} \left\{ \nu_1 \nu_3^* \right\} \mathbb{E} \left\{ \nu_2 \nu_3^* \right\} \mathbb{E} \left\{ \nu_3 \nu_3^* \right\} \left(80\right)
\]
We note that:

\[
\mathbb{E} \{ \nu_x \nu_y \} = \frac{1}{K} \sum_{k=1}^{K} \chi (\theta_k^t, \phi_k^t) \exp (j (u - v) \| k \| d \sin (\theta_k^r) \sin (\phi_k^r))
\]

for \( u, v = 1, \ldots, N_r \). Then from (80) and (81), we have:

\[
\text{det}(R) = \frac{1}{K^2} \sum_{k_1=1}^{K} \sum_{k_2=1}^{K} \sum_{k_3=1}^{K} \chi (\theta_{k_1}^t, \phi_{k_1}^t) \chi (\theta_{k_2}^t, \phi_{k_2}^t) \chi (\theta_{k_3}^t, \phi_{k_3}^t) F (\theta_{k_1}^r, \theta_{k_2}^r, \theta_{k_3}^r, \phi_{k_1}^r, \phi_{k_2}^r, \phi_{k_3}^r)
\]

where:

\[
F (\theta_{k_1}^r, \theta_{k_2}^r, \theta_{k_3}^r, \phi_{k_1}^r, \phi_{k_2}^r, \phi_{k_3}^r) = \\
\begin{bmatrix}
1 \\
+ \exp (-j \| k \| d [\sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) + \sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r) - 2 \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)]) \\
+ \exp (-j \| k \| d [2 \sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) - \sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r) - \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)]) \\
- \exp (-j \| k \| d [2 \sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) - 2 \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)]) \\
- \exp (-j \| k \| d [\sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) - \sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r)]) \\
- \exp (-j \| k \| d [\sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r) - \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)])
\end{bmatrix}
\]

which can be further simplified as follows:

\[
F (\theta_{k_1}^r, \theta_{k_2}^r, \theta_{k_3}^r, \phi_{k_1}^r, \phi_{k_2}^r, \phi_{k_3}^r) = \\
\begin{bmatrix}
1 \\
+ \cos (-\| k \| d [\sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) + \sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r) - 2 \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)]) \\
+ \cos (-\| k \| d [2 \sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) - \sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r) - \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)]) \\
- \cos (-\| k \| d [2 \sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) - 2 \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)]) \\
- \cos (-\| k \| d [\sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) - \sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r)]) \\
- \cos (-\| k \| d [\sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r) - \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)])
\end{bmatrix}
\]

where we have used similar observations as for \( N_r = 2 \).

Now, we need to compute \( \mathbb{E}_{\theta, \phi} (F (\theta^{1,r}, \theta^{2,r}, \theta^{3,r}, \phi^{1,r}, \phi^{2,r}, \phi^{3,r})) \). Let us define the following:

\[
a = \| k \| d \sin (\theta_{k_1}^r) \sin (\phi_{k_1}^r) \\
b = \| k \| d \sin (\theta_{k_2}^r) \sin (\phi_{k_2}^r) \\
c = \| k \| d \sin (\theta_{k_3}^r) \sin (\phi_{k_3}^r)
\]

By applying the following trigonometric identities:

\[
\cos (a + b - 2c) = \cos (a) \cos (b) \cos (2c) - \sin (a) \sin (b) \cos (2c) + \sin (a) \cos (b) \sin (2c) + \sin (b) \cos (a) \sin (2c) \\
\cos (c + b - 2a) = \cos (c) \cos (b) \cos (2a) - \sin (c) \sin (b) \cos (2a) + \sin (c) \cos (b) \sin (2a) + \sin (b) \cos (c) \sin (2a)
\]
and noting that $a$, $b$, and $c$ are independent, we eventually obtain the desired result after some algebraic manipulations.
