Abstract. We study the effect of the shape of different potential barriers on a transmitted charged current whose fermionic population is not monoenergetic but is described by means of an energy spectrum. The generalised kappa Fermi–Dirac distribution function is able to take into account both equilibrium and non-equilibrium populations of particles by changing the kappa index. Moreover, the corresponding current density can be evaluated using such a distribution. Subsequently, this progressive charged density arrives at the potential barrier, which is considered under several shapes, and the corresponding transmission factor is evaluated. This permits a comparison of the effects for different barriers as well as for different energy states of the incoming current.

Keywords: gases dynamics, large deviations in non-equilibrium systems, quantum gases, transport properties
1. Introduction

Potential barriers can be found in almost any field of physics. The usual procedure to study transmission considers a single particle or an ensemble with a given energy travelling through a potential barrier with a specific shape. In nuclear alpha decay [1] the probability of tunneling for a single alpha particle through the potential barrier created by the daughter nucleus and the alpha particle moving within is studied. Moreover, incoming currents of particles with an energy distribution travelling towards a potential barrier play an important role in the calculation of the reaction rates of stellar interiors [2]. The passing through barriers of charges are widely analysed in solid state physics, such as the study of charges with specific energy through a periodic potential [3]. Besides, concerning thermionically emitted current of electrons, the energy of the electron population progressing to the barrier at a solid surface is no longer monoenergetic, but such a current follows an energy distribution [4, 5]. In classical works [6], assuming the equilibrium, such electron population is described by means of the Fermi–Dirac distribution. In this later reference, the value of the transmitted current is calculated through a specific barrier, the so called hill potential. The main purpose of this work is to go further, by considering a charged fermionic population which can be found out of equilibrium. To achieve this goal we build a current using the generalised Fermi–Dirac distribution function [7, 8], which on taking low values of the kappa index is able to describe non-equilibrium populations. The equilibrium can be recovered with the $\kappa \rightarrow \infty$ limit. The corresponding current is studied travelling towards a barrier that has different representative shapes, namely, the step potential, the potential barrier, as well as a hill potential. Within the conclusions section, finally, we will briefly discuss these currents, but through the potential of an arbitrary shape.

1.1. The kappa distributions

The kappa distribution based on the generalised-Boltzmann statistics is a function widely used in astrophysics [9, 10]. An extension of such distribution into the quantum domain is the general expression for the Fermi Dirac generalised \( \kappa \)-distribution function [7, 8]. The generalised Fermi Dirac kappa function, can be cast in the framework of the quantum Boltzmann equation considering two-particle correlation functional containing correlational interactions of fermions. In the case of uncorrelated interactions, the two-particle correlation term becomes the usual Fermi two-particle correlation [7, 11]. At this point we should stress that the kappa generalised Fermi Dirac distribution is not the only way to describe a fermion population departing from equilibrium but producing the same large-kappa limit. A non-equilibrium function describing such fermions could be also built using the so-called relaxation time approximation [12]. In addition, a study of [13] concerning the field-free equilibration of excited nonequilibrium hot electrons in semiconductors shows the energy dependence of the relevant scattering rate plays an important role in determining the relaxation of the hot-electron distribution. Finally, again concerning the kappa distributions, a comprehensive study about their suitability to describe particle populations out of equilibrium can be found in [14]. This later work analyses the dynamics towards a large kappa limit within the physical framework of the Fokker–Planck equations.

The kappa Fermi Dirac distribution function has been used to study the behaviour of an electron population within solid state physics from a phenomenological point of view [15–17]. Moreover, the suitability of such a generalised function describing the thermionic emission under non equilibrium conditions has been tested by means of experiments [18]. Within the framework of the quantum Boltzmann equation mentioned above, the kappa Fermi Dirac function might model the energy spectrum of a fermionic gas at a temperature \( T \), and can be written in the following way [11],

\[
f_{\kappa}(T, E) = \left[ 1 + \left( \frac{1 + E - \epsilon_F}{E_\kappa + \epsilon_F} \right)^{(\kappa+1)} \right]^{-1}
\]

(1.1)

where \( E \) is the fermion energy, \( k_B \) the Boltzmann constant, and \( \epsilon_F \) being the Fermi energy. Hereafter we label, to shorten, \( E_\kappa = (\kappa - 3/2)k_B T \). The above expression has a physical meaning if \( \kappa > 3/2 \). As expected, for high kappa values corresponding to equilibrium, \( f_{\kappa \rightarrow \infty}(T, E) \) recovers the FD distribution. The above generalised FD distribution becomes smooth for low kappa values when \( (E - \epsilon_F) \ll k_B T \) or \( (E - \epsilon_F) \gg k_B T \). Under such conditions [15], the above function can be rewritten to describe the velocity distribution of the fermion population,

\[
f_{\kappa}(|v|) = C_{\kappa}(T) \left( 1 + \frac{\mu v^2 - \epsilon_F}{E_\kappa + \epsilon_F} \right)^{-\kappa+1}
\]

(1.2)

Here, \( m \) being the particle mass, \( \mu = m/2 \), and \( v^2 = (v_x^2 + v_y^2 + v_z^2) \) is the velocity. The constant \( C_{\kappa}(T) \) is normalized to the density of the electron population [15]. Such a distribution takes also into account the Fermi level. The suprathermal tails in the distribution develop for low \( \kappa > 3/2 \) values, whereas in the limit \( \kappa \rightarrow \infty \) the rhs of equation (1.2) reduces to a Maxwellian-like distribution.

Transmission through potential barriers with a generalised Fermi–Dirac current

2. Currents using the $\kappa$ distribution

Throughout this work we will deal with currents flowing along the positive $OX$ axis. The current density $J^0_\kappa$ parallel to the direction $u_x$ is given by,

$$J^0_\kappa = e \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} v_x f_\kappa d v$$  

(2.1)

where we set the additional superscript ‘0’ for convenience. Here, $v_{0x}$ is a given minimum velocity along the $OX$ axis that will be discussed later. We evaluate the current density $J_\kappa$ from equation (2.1) by using the $\kappa$ distribution (1.2).

$$J^0_\kappa = e C_\kappa(T) \int_{-\infty}^{\infty} v_x d v_x \int_{-\infty}^{\infty} d v_y \int_{-\infty}^{\infty} d v_z \left(1 + \frac{\mu(v_x^2 + v_y^2 + v_z^2) - \epsilon_F}{E_\kappa + \epsilon_F}\right)^{-(\kappa+1)}$$  

(2.2)

After integration over the $z$ and $y$-directions we have;

$$J^0_\kappa = e A_\kappa(\epsilon_F) \int_{-\infty}^{\infty} v_x d v_x \left(1 + \frac{\mu v_x^2 - \epsilon_F}{E_\kappa + \epsilon_F}\right)^{-\kappa}$$  

(2.3)

where $A_\kappa(\epsilon_F)$ is a term that depends on its Fermi level and the state of the fermion population through the $\kappa$ index. As we shall see, we will work in terms of the energy along the $OX$ axis, and the final form of such integral will be later rewritten.

2.1. Transmission coefficient and normalisation to the incident current

As it is well known, if we set a potential barrier at a given point with an incoming charged current, the transmission coefficient will determine the reflection rate of such a current. Therefore, the corrected form for the current density should include the quantum transmission coefficient $B(|p|)$ which is a function of the momentum of the incoming particles. At this point, we take this transmission coefficient $B(v_x)$ along the $OX$ axis. This coefficient is included within the integral:

$$J_B^0 = e \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} v_x f_\kappa B(v_x) d v_x d v_y d v_z$$  

(2.4)

Again, we label this corrected current density with the superscript ‘$B$’ for convenience. Using the equation (1.2) in equation (2.4) after the integration over $v_y$ and $v_z$, its corresponding contribution reads,

$$J_\kappa = e A_\kappa(\epsilon_F) \int_{-\infty}^{\infty} v_x \left(1 + \frac{\mu v_x^2 - \epsilon_F}{E_\kappa + \epsilon_F}\right)^{-\kappa} B(v_x) d v_x$$  

(2.5)

The lower integration limit, $v_{0x}$, will then physically correspond to the velocity minimum to overcome the potential barrier. This minimum will depend on the shape of
each barrier. Usually, the normalisation constant of the distribution function \( f_\kappa \) entangles the information about the particle density and other physical parameters of the gas which constitute the current flowing towards the barrier. However, the exact knowledge about these quantities sometimes cannot be achieved. Therefore, as we are interested in the effect of the barriers on such charged currents, we will normalise the transmitted current density, equation (2.5), to the incident one without the presence of the barrier, equation (2.3): the norm \( N \) will be \( J_0^\kappa \).

\[
J_\kappa \equiv \frac{J^B_\kappa}{N} = \frac{J^B_\kappa}{J_\kappa^0} \tag{2.6}
\]

Hereafter we will consider the energy of the particle distribution along the \( OX \) axis, \( E = mv^2_x/2 \). The corresponding energy minimum to overcome the potential barrier is labelled as \( E_0 = mv^2_0/2 \). Therefore, using equations (2.3) and (2.5) in equation (2.6), the normalised current density in terms of the energy finally reads,

\[
J_\kappa = \frac{1}{N} \int_{E_0}^{+\infty} \left( 1 + \frac{E - \epsilon_F}{E_\kappa + \epsilon_F} \right)^{-\kappa} B(E) dE \tag{2.7}
\]

with

\[
N = \int_{E_0}^{+\infty} \left( 1 + \frac{E - \epsilon_F}{E_\kappa + \epsilon_F} \right)^{-\kappa} dE \tag{2.8}
\]

Here the transmission coefficient \( B(E) \) will be written in terms of the energy. Actually, if we take into account the distribution function of the incoming particles, equation (2.7) can be regarded to some extent as an average of the transmission coefficient over the \([E_0, +\infty]\) energy range.

3. Step potential

The step potential is the simplest model for a potential barrier. The physical picture would correspond to a charged current which feels an abrupt change between two regions that have different potentials. We set the step at \( x = 0 \), and we label the negative region with ‘1’, and the positive one with ‘2’. Namely,

\[
V_1(x < 0) = 0; \quad V_2(x \geq 0) = V_0
\]

In this case the particles must have a minimum energy of \( E_0 = V_0 \), otherwise the wave function within region two would decay exponentially. Thus, we will insert this \( E_0 \) value within the corresponding norm \( N \), in equations (2.7) and (2.8). From the grounds of quantum mechanics, see for instance [19], the corresponding barrier coefficient can be found: The particles have a wave function, which is a linear combination of \( \Psi_1 \sim \exp(\pm ip_1x/\hbar) \) in the region one, with momentum \( p_1 = \sqrt{2mE} \). As the particles must have energies \( E > V_0 \), in region two the wave function is written in terms of \( \Psi_2 \sim \exp(\pm ip_2x/\hbar) \) with momentum \( p_2 = \sqrt{2m(E - V_0)} \). We use the continuity
of the wavefunctions and their corresponding derivatives at the $x = 0$ point. After a long but straightforward calculation, the transmission coefficient yields,

$$B(E) = \frac{4 p_1 p_2}{(p_1 + p_2)^2} \tag{3.1}$$

If we perform the change of variable $u \equiv (E - V_0)/(k_B T)$, then the barrier coefficient takes the form,

$$B(u) = \frac{4\sqrt{u k_B T} \sqrt{u k_B T + V_0}}{(\sqrt{u k_B T} + \sqrt{u k_B T + V_0})^2} \tag{3.2}$$

We will focus on the case $k_B T/V_0 \ll 1$, then by expanding $B(u)$ and labelling $Q = V_0/k_B T$, we can find the simplified form

$$B(u) = 4\sqrt{u/Q} \left[ 1 - 2\sqrt{u/Q} - \frac{5}{2} (u/Q) + \ldots (h.c.) \right] \tag{3.3}$$

Inserting this later transmission term and the equation (2.8) within the equation (2.7), after calculations, we finally attain,

$$J_k = \frac{(2\kappa - 1) \sqrt{\pi}}{\sqrt{2}Q} \times \left[ \frac{\Gamma\left(\kappa - \frac{3}{2}\right) (2Q + 2\kappa - 3)^{1/2}}{\Gamma(\kappa)} - \frac{2\sqrt{2} 2Q + 2\kappa - 3}{\sqrt{\pi}Q \kappa^2 - 3\kappa + 2} - \frac{15\Gamma\left(\kappa - \frac{5}{2}\right) (2Q + 2\kappa - 3)^{3/2}}{8Q\Gamma(\kappa)} \right]. \tag{3.4}$$

We can observe that the above normalised current does not depend on the mass of the incoming particles. Using the asymptotic form of the Gamma function [20], in the equilibrium limit ($\kappa \to \infty$), from the above equation we obtain,

$$J_{\kappa \to \infty} = 4\sqrt{k_B T/V_0} \left[ \sqrt{\pi}/2 - 2\sqrt{k_B T/V_0} - \frac{15\sqrt{\pi}}{8} (k_B T/V_0) \right] \tag{3.5}$$

In figure 1(A) is shown the evolution of the normalised current $J_\kappa$ as a function of the temperature. We observe the drop in the current. In all of these cases this decay is faster as the current departs from the equilibrium. Figure 1(B) shows the evolution of the normalised current $J_\kappa$ as a function of the potential $V_0$. Here we can observe the change in behaviour depending on the kappa index: a current near equilibrium rises and then it drops slowly as $V_0$ increases. The non-equilibrium currents, after the corresponding growth, saturate to an asymptotic value.
Transmission through potential barriers with a generalised Fermi–Dirac current

Figure 1. Left-(A) The normalised current density $J_\kappa$ with a step potential as a function of temperature for different $\kappa$ values. Right-(B) The normalised current density $J_\kappa$ with a step potential as a function of $V_0$ for different $\kappa$ values.

4. Barrier

The physical picture of the barrier potential would correspond to a charged current which experiences an abrupt change in potential in a given width between two regions which have the same potential. We put the barrier of thickness $d$ at $x = 0$, and we label ‘1’ the negative region, ‘2’ is the label for the positive one in which the potential changes, and ‘3’ is the positive region which has the same potential as in region one. Namely,

$$V_1(x < 0) = 0; \quad V_2(0 \leq x \leq d) = V_0; \quad V_3(x > d) = 0$$

As it is well known, the particles can penetrate the barrier with the minimum energy of $E_0 = 0$. Thus, we will insert this minimum value within equation (2.7) and into the corresponding norm $N$, equation (2.8). Following the general procedure [19], the corresponding barrier coefficient can be found: the particles have a wavefunction $\Psi_1 \sim \exp(\pm ip_1x/\hbar)$ in the region one, and the same wavefunction in the region three, with momentum $p_1 = \sqrt{2mE}$. In region two, corresponding to a barrier of height $V_0$, we need to distinguish between particle energies below or above $V_0$: if $E < V_0$ the wave function is written in terms of $\Psi_2 \sim \exp(\pm p_2x/\hbar)$, with $p_2 = \sqrt{2m(V_0 - E)}$. If $E > V_0$ the wave function becomes complex, and it is written in terms of $\Psi_2 \sim \exp(\pm ip'_2x/\hbar)$ with $p'_2 = \sqrt{2m(E - V_0)}$. After calculations, following the same process as in the previous section, the corresponding transmission coefficients are attained:

$$B(E < V_0) = \left[ 1 + \frac{\sinh^2(p_2d/\hbar)}{4\frac{E}{V_0}\left[ 1 - \frac{E}{V_0} \right]} \right]^{-1}$$

(4.1)
Transmission through potential barriers with a generalised Fermi–Dirac current

The above expression can be simplified if we distinguish the energy ranges: if $E \ll V_0$, keeping the first order, equation (4.1) becomes,

$$B_1(E << V_0) = 16 \frac{E}{V_0} \exp \left[ -\frac{2d}{\hbar} \sqrt{2mV_0} \right]$$

(4.2)

If $E \simeq V_0$, equation (4.1) can be put as,

$$B_2(E \simeq V_0) = \frac{1}{1 + \frac{mV_0}{2\hbar^2}}$$

(4.3)

The calculation of the transmission coefficient in the energy range $E > V_0$ yields,

$$B_3(E > V_0) = \left[ 1 + \sin^2 \left( \frac{p_2 d}{\hbar} \right) \frac{4E}{E_0} \left( \frac{E}{V_0} - 1 \right) \right]^{-1}$$

(4.4)

This later expression for energies $E \gg V_0$ can be approximated to unity. As we have the expressions of $B(E)$, we will attain the corresponding normalised current density as

$$J_\kappa = \frac{1}{N} \int_0^{V_0 - \Delta} \left( 1 + \frac{E - \epsilon_F}{E_\kappa + \epsilon_F} \right)^{-\kappa} B_1(E) dE + \frac{1}{N} \int_{V_0 - \Delta}^{V_0 + \Delta} \left( 1 + \frac{E - \epsilon_F}{E_\kappa + \epsilon_F} \right)^{-\kappa} B_2(E) dE$$

$$+ \frac{1}{N} \int_{V_0 + \Delta}^{\infty} \left( 1 + \frac{E - \epsilon_F}{E_\kappa + \epsilon_F} \right)^{-\kappa} B_3(E) dE$$

(4.5)

Where $\Delta = \alpha V_0$ with $0 < \alpha < 1$. Using equations (2.8) and (4.2)–(4.4) within (4.5), and after integration we obtain,

$$J_\kappa = \frac{\kappa - 1}{\kappa - 3/2} \left[ \frac{16}{V_0} I_1(E = V_0 - \Delta) - I_1(E = 0) \right] \exp \left\{ -\frac{2d}{\hbar} \sqrt{2mV_0} \right\}$$

$$+ \left( 1 + \frac{mV_0}{2\hbar^2} \right) I_2(E = V_0 + \Delta) - \frac{1}{1 + \frac{mV_0}{2\hbar^2}} I_2(E = V_0 - \Delta)$$

(4.6)

where, to shorten the expression we introduce,

$$I_1(E) = -\frac{E_\kappa^2 - \kappa E_\kappa E + (\kappa - 1)E^2}{(\kappa - 1)(\kappa - 2) k_B T} \left( 1 + \frac{E}{E_\kappa} \right)^{-\kappa}$$

$$I_2(E) = -\frac{E_\kappa}{\kappa - 1} \left( 1 + \frac{E}{E_\kappa} \right)^{-\kappa+1}$$

https://doi.org/10.1088/1742-5468/ab7af1
Transmission through potential barriers with a generalised Fermi–Dirac current

Figure 2. Values of the transmitted proton current density as a function of the thickness $d \in [10^{-10}, 10^{-4}]$ for a potential barrier of height $V_0 = 150$ eV. $T = 5000$ K.

In the equilibrium limit, $\kappa \to \infty$, equation (4.6) yields,

$$J_{\kappa \to \infty} = 16 \exp \left[ -\frac{2d}{\hbar} \sqrt{2mV_0} \right] \left[ \frac{k_B T}{V_0} - \exp \left( -\frac{V_0 - \Delta}{k_B T} \right) \left( \frac{k_B T}{V_0} + \frac{\Delta}{V_0} - 1 \right) \right]$$

$$+ \frac{1}{1 + \frac{mV_0^2}{2\hbar^2}} \left[ \exp \left( -\frac{V_0 + \Delta}{k_B T} \right) - \exp \left( -\frac{V_0 - \Delta}{k_B T} \right) \right] - \exp \left( -\frac{V_0 - \Delta}{k_B T} \right)$$

(4.7)

In this case, from equation (4.6), we see that the transmitted current is sensitive to the mass of the incoming particles. From the above calculation we can perform an analysis of the behaviour of the current density as a function of the temperature. In this case we can realize a weak dependence on the kappa index. Hence, the current can be considered the same for all finite kappa values. The equilibrium $\kappa \to \infty$ can only be distinguished from the others at higher temperatures. The behaviour of the $J_\kappa$ as a function of $V_0$ is the same in the case of the current in equilibrium as for currents with finite kappa values—all of them almost decay with the same exponential. Concerning the variation of $J_\kappa$ as a function of the barrier width, for an electron current the dominant term is the exponential decay with a weak dependence on the kappa values. The behaviour for a proton current can be seen in figure 2. Here the kappa value becomes significant. The value of the current density which can be transmitted will be determined by the kappa index.

5. Hill potential

The physical picture of the hill potential would correspond to a charged current which feels an abrupt change at the interfaces of three regions with different potentials. The
Figure 3. Values of the transmitted proton current density as a function of the temperature through a hill potential barrier of height $V_1 = 200$ eV, $V_0/V_1 = 1.3$.

Figure 4. Values of the transmitted proton current density as a function of $V_1$ through a hill potential barrier at temperature $T = 5000$ K, with $V_0/V_1 = 3.5$.

Incoming current travels along a region with a ground potential. Subsequently, it penetrates into a region of width, $d$, and potential $V_0$. Finally, the current enters into a region with a potential $V_1 < V_0$, and greater than the ground. This kind of potential has been studied by [6] in relation to the thermionic emission from a metal surface. Reference [6] uses an incoming current obeying an equilibrium Fermi–Dirac distribution. Such a case will correspond to the equilibrium limit in this work. We set the barrier with thickness $d$ at $x = 0$, and we label ‘1’ the negative region, ‘2’ the positive one in which the potential changes to $V_0$, and ‘3’ the positive region after the thickness $d$, in which the corresponding potential is $V_1$.

$$V_1(x < 0) = 0; \quad V_2(0 \leq x \leq d) = V_0; \quad V_3(x > d) = V_1(V_1 < V_0)$$

https://doi.org/10.1088/1742-5468/ab7af1
In this case the particle wavefunction cannot travel across the region three unless it has a minimum energy $E_0 = V_1$, otherwise the corresponding wavefunction within this region becomes a decreasing exponential. Therefore we insert this minimum into the corresponding norm $N$, equation (2.8) and within equation (2.7). The corresponding transmission coefficient through this kind of barrier can be found from [6]. For convenience we perform the following changes

$$u \equiv \frac{E - V_1}{k_B T}; \quad a \equiv \frac{V_1 - \epsilon_F}{k_B T}; \quad \gamma \equiv \frac{\epsilon_F}{k_B T}$$

Hence, we can rewrite and split equation (2.7) as follows:

$$J_\kappa = \frac{k_B T}{N} \int_0^{\frac{V_0 - V_1}{k_B T}} \left(1 + \frac{u + a}{\kappa - 3/2 + \gamma}\right)^{-\kappa} B_1(u) du$$

$$+ \frac{k_B T}{N} \int_{\frac{V_0 - V_1}{k_B T}}^{\infty} \left(1 + \frac{u + a}{\kappa - 3/2 + \gamma}\right)^{-\kappa} B_2(u) du$$

(5.1)

In the evaluation of the second integral $V_1 + u k_B T > V_0$, and therefore throughout this range of integration the transmission coefficient $B_2(u)$ will approximate to unity. The transmission coefficient $B_1(u)$ in equation (5.1), within the involved range of energies, following [6] and using the standard procedures, can be obtained as follows,

$$B_1(u) = \frac{16}{V_0(V_0 - V_1)} \sqrt{u k_B T (V_1 + u k_B T) (V_0 - V_1 - u k_B T)}$$

$$\times \exp \left[-\frac{2d}{\hbar} \sqrt{2m(V_0 - V_1 - u k_B T)}\right]$$

(5.2)
Transmission through potential barriers with a generalised Fermi–Dirac current

The above expression with \((u_b T / V_1) \ll 1\) can be expanded and simplified to,

\[
B_1(u) = \frac{16}{V_0} \sqrt{V_1 k_B T} \exp \left[ -\frac{2d}{\hbar} \sqrt{2m(V_0 - V_1)} \right] u
\]

(5.3)

If we label \(U_M \equiv (V_0 - V_1)/k_B T\) and \(Q \equiv V_1/k_B T\), finally by inserting equations (2.8) and (5.3) into equation (5.1) we attain,

\[
J_\kappa = \left( \frac{E_\kappa + V_0}{E_\kappa + V_1} \right)^{-\kappa+1} \left[ 1 + \sqrt{\frac{V_1}{V_0 - V_1}} \frac{16k_B T (\kappa - 1)}{V_0 - V_1 (4\kappa(\kappa - 2) + 3)} C_0(\kappa, U_M, Q) \right]
\times \exp \left[ -\frac{2d}{\hbar} \sqrt{2m(V_0 - V_1)} \right]
\]

(5.4)

where, to shorten, the \(C_0(\kappa, U_M, Q)\) term reads,

\[
C_0(\kappa, U_M, Q) \equiv 2U_M - 2Q + 3 - 2\kappa(2U_M - 1) + (2\kappa + 2Q - 3)_2
\times _2F_1 \left[ 1; \frac{1}{2} - \kappa; \frac{1}{2}; \frac{-U_M}{Q + \kappa - 3/2} \right]
\]

and \(_2F_1(a; b; c; z)\) represents the ordinary hypergeometric function [20]. By means of the corresponding calculation in the equilibrium case, we attain,

\[
J_{\kappa \to \infty} = \exp \left( -\frac{V_0 - V_1}{k_B T} \right) + \frac{16k_B T}{V_0} \sqrt{k_B T V_1} \exp \left[ -\frac{2d}{\hbar} \sqrt{2m(V_0 - V_1)} \right]
\times \left[ \sqrt{\frac{\pi}{2}} \text{Erf} \left\{ \sqrt{\frac{V_0 - V_1}{k_B T}} \right\} - \sqrt{\frac{V_0 - V_1}{k_B T}} \exp \left( -\frac{V_0 - V_1}{k_B T} \right) \right]
\]

(5.5)

where \(\text{Erf}(x)\) stands for the Error function [20]. In figure 3 we observe the corresponding normalised current as a function of temperature: The transmitted currents out of equilibrium (with low \(\kappa\) values) are greater than the classical Fermi–Dirac case corresponding to equilibrium. In all cases, the current is almost constant with the temperature. Figure 4 shows the normalised current as a function of the \(V_1\) potential. For all \(\kappa\) values the current decays as the potential increases, but the value of the current density when the fermionic population departs from the classical Fermi–Dirac distribution becomes greater. In figure 5 we observe the decay of currents with different \(\kappa\) values as a function of the quotient \(V_0/V_1\). In this case the decay is faster for the equilibrium \((\kappa \to \infty)\) currents.

6. Conclusions

In this work, we use the generalised Fermi Dirac distribution function to build a current. These currents have been studied travelling through several barriers with different representative shapes as: the step potential, the potential barrier, and also the hill potential. The resulting currents have been later compared with those of the equilibrium limit.
Transmission through potential barriers with a generalised Fermi–Dirac current

The transmitted current through both the step and hill potentials are quite sensitive to the shape of the potential as well as to the degree of departure from equilibrium. On the contrary, concerning the barrier, the transmission is almost completely independent of the kappa values for electron currents, and slightly in the case of protons. A subsequent task coming up here is to study the transmission of a kappa current through a (smoothed) barrier of an arbitrary shape. This task could be done following the same procedure we follow along in this work. Previously, the corresponding transmission coefficient could be computed as a juxtaposition of square potential barriers of thickness $\Delta x$. The height of potential would be suitable to the corresponding height of the modelled potential at this $x$ point, $V(X)$. Using the WKB approximation this could be written as:

$$\ln[B(E)] \approx -2 \int_{\text{Barrier}} \, dx \sqrt{2m(V(x) - E)/\hbar^2}$$

and later inserting such a term into equation (2.7) to obtain the transmitted current. However, it entangles to numerically fit the modelled potential the height of $V(X)$, as well as the thickness $\Delta x$. Hence, this task turns out to be a numerical issue, which is left for a further work.
