Abstract. We give conditions for unitarizability of Harish-Chandra super modules for Lie supergroups and superalgebras.

1. Introduction

Let \( g \) be a real Lie superalgebra. It is natural to ask how to define the concept of (infinitesimal) unitarity or unitarizability for a super module \( V \) for \( g \) and how to obtain, starting from \( V \), a unitary module for \( G \) a Lie supergroup with \( g = \text{Lie}(G) \), \( G_0 \) simply connected. Let \( \gamma \) be the representation of \( g \) in \( V \). We say \( \gamma \) is unitary if \( V \) is equipped with an hermitian product in which \( V_0 \) and \( V_1 \) are orthogonal, and the following conditions are met (see [3, 10] and also [20, 24]):

(U1) For all \( Z \in g_0 \), \( i\gamma(Z) \) is symmetric on \( V \).
(U2) For all \( X \in g_1 \), \( \rho(X) := e^{-i\pi/4} \gamma(X) \) is symmetric on \( V \).

These are not enough in general to define in the completion \( \mathcal{H} \) of \( V \) a unitary representation of a Lie supergroup \( G \), with \( g = \text{Lie}(G) \), whose infinitesimal form on \( V \) is \( \gamma \). Indeed, as was remarked in Nelson [21], this is already not enough in the classical setting, that is when \( g_1 = 0 \). In general, we need an additional condition:

(U3) There is an even unitary representation \( \pi_0 \) of \( G_0 \), the simply connected group defined by \( g_0 \), on the completion \( \mathcal{H} \) of \( V \) such that \( d\pi_0(Z) \) is defined on \( V \) for all \( Z \in g_0 \) and coincides with \( \gamma(Z) \) on \( V \); in the usual notation \( V \subset \mathcal{H} \) and \( \gamma(Z) \prec d\pi_0(Z) \), \( Z \in g_0 \) (see [23] Ch. 8 for definitions and notation).

We recall here that \( d\pi_0(Z) \) is the unique self adjoint operator on \( \mathcal{H} \) such that \( \pi_0(\exp(tZ)) = e^{itd\pi_0(Z)} \). Then, Proposition 3 of [3] leads to the following theorem.

**Theorem 1.1.** Let \( V \) be a module for a real Lie superalgebra \( g \), via the representation \( \gamma \) such that conditions (U1)-(U3) are satisfied. Suppose that \( V \subset C^{\omega}(\pi_0) \). Then each \( \rho(X) \) \( (X \in g_1) \) is essentially self-adjoint on \( V \) with \( C^{\omega}(\pi_0) \subset D(\rho(X)) \), and there is a unique unitary representation \( (\pi_0, \rho, \mathcal{H}) \) of the Lie supergroup \( (G_0, g) \) in \( \mathcal{H} \) such that \( \rho(X) \) is the restriction to \( C^{\omega}(\pi_0) \) of \( \rho(X) \) for all \( X \in g_1 \).

The shortcoming of this theorem is that it assumes the existence of \( \pi_0 \). As we shall see, when \( g_0 \) is reductive and the modules are Harish-Chandra modules of \( (g, k) \)-type, then we can dispense with (U3) entirely. As a notational convention, when we say that some module is a Harish-Chandra module, we assume it is already of...
whose SHCP is.

Let $G$ be a real Lie superalgebra with $g_{0}$ reductive acting via $\gamma$ on a complex vector superspace $V$. Assume:

$(U1)$ For all $Z \in g_{0}$, $i_{\gamma}(Z)$ is symmetric on $V$.

$(U2)$ For all $X \in g_{0}$, $\rho(X) := e^{-ir/4}\gamma(X)$ is symmetric on $V$.

Let $G_{0}$ be the simply connected Lie group defined by $g_{0}$ and let $G$ be the supergroup whose SHCP is $(G_{0}, g)$. If $V$ is finitely generated, then there is a unique unitary representation of the Lie supergroup $G$ on the completion $\mathcal{H}$ of $V$, say $(\pi_{0}, \rho, \mathcal{H})$ such that $V \subset C^{\omega}(\pi_{0})$.

We shall prove the following.

**Theorem 1.2.** Let $g$ be a real Lie superalgebra with $g_{0}$ reductive acting via $\gamma$ on a complex vector superspace $V$. Assume:

$($U$1)$ For all $Z \in g_{0}$, $i_{\gamma}(Z)$ is symmetric on $V$.

$($U$2)$ For all $X \in g_{0}$, $\rho(X) := e^{-ir/4}\gamma(X)$ is symmetric on $V$.

Let $G_{0}$ be the simply connected Lie group defined by $g_{0}$ and let $G$ be the supergroup whose SHCP is $(G_{0}, g)$. If $V$ is finitely generated, then there is a unique unitary representation of the Lie supergroup $G$ on the completion $\mathcal{H}$ of $V$, say $(\pi_{0}, \rho, \mathcal{H})$ such that $V \subset C^{\omega}(\pi_{0})$.

We turn then to infinitesimal unitarity. Let $g_{C}$ the complexification of $g$, $g = \mathfrak{k} \oplus \mathfrak{p}$ the Cartan decomposition and assume $g_{C}$ contragredient. Assume $g$ is equal rank, that is $\text{rk}(\mathfrak{k}) = \text{rk}(\mathfrak{g})$ and that $\mathfrak{k}$ has a non trivial center (see [6, 5]). Fix $h_{C}$ a Cartan subalgebra of $\mathfrak{k}_{C}$ and $g_{C}$. Let $\Delta$ be the root system of $g_{C}$, $g_{C} = h_{C} \oplus \sum_{\alpha \in \Delta} g_{\alpha}$ the root space decomposition. The equal rank condition allows us to decompose $\mathfrak{k}_{C}$, $\mathfrak{p}_{C}$ into root spaces; we say that a root $\alpha$ is compact (non compact) if $g_{\alpha} \subset \mathfrak{k}_{C}$ ($g_{\alpha} \subset \mathfrak{p}_{C}$). Let $\beta : Z(g_{C}) \rightarrow S(h_{C})^{W}$ denote the Harish-Chandra homomorphism (see [19, 15]). We prove the following result.

**Theorem 1.3.** Let $\lambda \in h_{C}^{\ast}$ and let $\pi_{\lambda}$ be the irreducible highest weight representation of highest weight $\lambda$. Then $\pi_{\lambda}$ is unitary if and only if $(-i)^{a}[\alpha](a'\alpha)(\lambda) > 0$ for all $a \in U(g_{C})$. In particular it is necessary that $\lambda(H_{\alpha}) \geq 0$ for $\alpha$ compact and $\lambda(H_{\alpha}) \leq 0$ for $\alpha$ non compact even roots.

In the end we give an explicit example regarding $g_{C} = \text{osp}_{C}(1|2)$ and its real form $\text{osp}_{R}(1|2)$ ([11] Appendix A) proving the following.

**Theorem 1.4.** Let $V_{t}$ be the universal (Verma) $\text{osp}_{C}(1|2)$ module of highest weight $t$.

1. Then $V_{t}$ is irreducible and it is a unitary module for $\text{osp}_{R}(1|2)$ if and only if $t$ is real and negative.

2. All unitary representation of the real Lie supergroup $\text{Osp}_{R}(1|2) = (\text{SL}_{2}(\mathbb{R}), \text{osp}(1|2))$ are given on the completion $\mathcal{H}$ of $V_{t}$, and are such that $V_{t} \subset C^{\omega}(\pi_{0})$, $\pi_{0}$ unitary representation of $\text{SL}_{2}(\mathbb{R})$ in $\mathcal{H}$ integrating $(V_{t})_{0}$.

**Acknowledgements.** R.F. and C.C. wish to thank the UCLA Dept. of Mathematics for the warm hospitality during the realization of part of this work. R.F. research was funded by EU grant GHAIA 777822.
2. \((\mathfrak{g}, \mathfrak{t})\)-SUPERMODULES AND THEIR UNITARITY

2.1. Harish-Chandra modules for reductive Lie algebras. Let \( \mathfrak{g} \) be a real reductive Lie algebra. Then \( \mathfrak{g} = \mathfrak{g}' \oplus \mathfrak{c} \) where \( \mathfrak{c} \) is the center of \( \mathfrak{g} \) and \( \mathfrak{g}' = [\mathfrak{g}, \mathfrak{g}] \) is semisimple. Let \( \mathfrak{t} \subset \mathfrak{g}' \) be a maximal subalgebra of compact type, which means that it is the set of fixed points of a Cartan involution of \( \mathfrak{g}' \). Let \( V \) be a \((\mathfrak{g}', \mathfrak{t})\)-module. We recall that this means that \( V \) is a \( \mathfrak{g}' \)-module which, as a \( \mathfrak{t} \)-module, is a direct sum of finite dimensional irreducible \( \mathfrak{t} \)-modules. Recall also that \( \mathfrak{t} \) is reductive in \( \mathfrak{g} \). Note that if \( V \) is irreducible, then \( \mathfrak{c} \) acts through an additive character on \( V \) and so \( V \) is an irreducible \((\mathfrak{g}, \mathfrak{k})\)-module. This allows a reduction to the case when \( \mathfrak{g} \) is itself semisimple. One knows from Harish-Chandra’s work (slightly modified to include the reductive case) that if \( V \) is irreducible, or more generally, is finitely generated as a \( \mathcal{U}(\mathfrak{g}') \)-module on which \( \mathfrak{c} \) acts semi simply through a finite number of additive characters, then the isotypical subspaces \( V_\theta \) are all finite dimensional, where \( \theta \) runs through the set \( \hat{\mathfrak{k}} \) of equivalence classes of irreducible finite dimensional representations of \( \mathfrak{k} \) (\( \mathfrak{k} \) is not in general semisimple, see [27] for details). A basic question in the theory of \((\mathfrak{g}, \mathfrak{t})\)-modules is whether such a module is the module of \( \mathfrak{k} \)-finite vectors of a Hilbert space representation (not necessarily unitary) of the simply connected group \( G \) defined by \( \mathfrak{g} \). In his paper [12], Harish-Chandra proved this for irreducible \((\mathfrak{g}, \mathfrak{t})\)-modules which satisfy a certain condition. He later verified that this condition is satisfied for highest weight \((\mathfrak{g}, \mathfrak{t})\)-modules and so all such modules can be realized as the \( \mathfrak{k} \)-finite vectors of Hilbert space representations of \( G \). This is actually sufficient for our purposes. However, it is possible to remove the special condition imposed by Harish-Chandra in his Theorem 4 in [12]. The general result is as follows (see [28], Ch. 8).

**Theorem 2.1.** Any \((\mathfrak{g}, \mathfrak{t})\)-module \( V \) which is a direct sum of a finite number of irreducible submodules is identifiable as the module of \( \mathfrak{k} \)-finite vectors of a Hilbert space (not necessarily unitary) representation \( \pi \) of \( G \). Moreover \( V \subset C^\omega(\pi) \).

As mentioned earlier, when we deal with irreducible highest weight Harish-Chandra modules, the above general result is not needed, and Harish-Chandra already proves the above theorem for these modules. The question arises if an irreducible \((\mathfrak{g}, \mathfrak{t})\)-module \( V \), which is infinitesimally unitary, is the module of \( \mathfrak{k} \)-finite vectors of an irreducible unitary representation of \( G \). In [12] Harish-Chandra proves that such a unitary representation exists and is unique up to equivalence provided \( V \) is the module of \( \mathfrak{k} \)-finite vectors of a Banach space representation of \( G \) (Theorem 9, [12]). In view of the above remarks and results, we can now state the following theorem.

**Theorem 2.2.** Let \( V \) be an irreducible \((\mathfrak{g}, \mathfrak{t})\)-module defined by the representation \( \gamma \) of \( \mathcal{U}(\mathfrak{g}) \), which is unitary in the sense that there is a hermitian product \( (, ) \) on \( V \) such that \( i\gamma(X) \) is symmetric for all \( X \in \mathfrak{g} \). Then, there is a unitary representation of \( G \) (unique up to unitary equivalence) in the completion \( \mathcal{H} \) of \( V \) with respect to the norm defined by the hermitian product, such that \( V \) is the module of \( \mathfrak{k} \)-finite vectors in \( \mathcal{H} \).

2.2. Unitarity of super modules. We shall now present a proof that for a Lie superalgebra \( \mathfrak{g} \) with \( \mathfrak{g}_0 \) reductive, conditions (U1) and (U2) of Sec. 1 are enough to
guarantee the existence of a unitary representation of the Lie supergroup. Let \( \mathfrak{g} \) be a Lie superalgebra with \( \mathfrak{g}_0 \) reductive. Write, as in Subsec. 2.1, \( \mathfrak{g}_0 = \mathfrak{g}'_0 \oplus \mathfrak{c}_0 \). \( \mathfrak{c}_0 \) is the subalgebra of \( \mathfrak{g}'_0 \) fixed by a Cartan involution.

**Lemma 2.3.** Let \( V \) be a \((\mathfrak{g}_0, \mathfrak{c}_0)\)-module. If \( V \) admits a hermitian product which is \( \mathfrak{c}_0 \)-invariant, namely, elements of \( \mathfrak{c}_0 \) are skew symmetric with respect to it, then the isotypical subspaces \( V_\theta \) are mutually orthogonal.

**Proof.** Let \( V_1, V_2 \) be two irreducible \( \mathfrak{c}_0 \)-stable finite dimensional subspaces such that they carry inequivalent representations of \( \mathfrak{c}_0 \). We want to prove that \( V_1 \perp V_2 \). Let \( W = V_1 \oplus V_2 \). Let \( P \) be the orthogonal projection \( V_1 \rightarrow V_2 \) in \( V \). We claim that \( P \) is a \( \mathfrak{c}_0 \)-map. Let \( u \in V_1 \), write \( u = x + y \) where \( x \in V_2, y \in W, y \perp V_2 \), or \( y \in V_2^\perp \cap W \). Then \( Pu = x \) and for \( X \in \mathfrak{c}_0, XPu = Xx \). On the other hand, \( Xu = Xx + Xy \) and we know that \( Xx, Xy \) are orthogonal by \( \mathfrak{c}_0 \)-invariance. Hence \( PXu = Xx = XPu \), proving the claim. This implies that \( P = 0 \), as otherwise \( P \) will be a nonzero \( \mathfrak{c}_0 \)-map between \( V_1 \) and \( V_2 \).

**Lemma 2.4.** Suppose that \( V \) is a unitary \((\mathfrak{g}_0, \mathfrak{c}_0)\)-module such that the \( V_\theta \) are all finite dimensional. Then for any submodule \( W \subset V \), \( W^\perp \) is also a submodule, and \( V = W \oplus W^\perp \).

**Proof.** It is only a question of proving that \( V = W \oplus W^\perp \). The point is that \( V \) is in general not complete. Now \( W = \oplus_\theta W_\theta \) where the \( W_\theta \) are finite dimensional and mutually orthogonal, and \( V_\theta \subset V_\theta \). Let \( W' \) be the orthogonal complement of \( W_\theta \) in \( V_\theta \). Since the isotypical subspaces of \( V \) are mutually orthogonal, it is clear that \( W'_\theta \) is \( \perp \) to all \( V_{\theta'} \) for \( \theta' \neq \theta \). Thus \( W'_\theta \subset W^\perp \). Since this is true for all \( \theta \), we see that \( W \oplus W^\perp \supset W_\theta \oplus W'_\theta = V_\theta \) for all \( \theta \) (as the \( V_\theta \) are finite dimensional). So \( W \oplus W^\perp = V \).

**Lemma 2.5.** If \( V \) is as in the previous lemma, then \( V \) is the orthogonal direct sum of irreducible submodules.

**Proof.** We shall first show that if \( W \subset V \) is any submodule, then \( W \) has an irreducible submodule. This is a standard argument of Harish-Chandra. Consider pairs \((W', \theta)\) for submodules \( W' \subset W \) and \( \theta \) such that \( W'_\theta \neq 0 \). Among these choose one for which \( W'_\theta \) has the smallest dimension; let \((W', \theta)\) be the corresponding pair. Let \( W'' \) be the cyclic submodule of \( W' \) generated by \( W'_\theta \). If \( L \) is a proper submodule of \( W'' \), then we claim that \( L \cap W'_\theta \) is either 0 or equal to \( W'_\theta \). Otherwise \( \dim(L_\theta) \) is positive and strictly less than \( \dim(W'_\theta) \), a contradiction. It cannot equal \( W'_\theta \), as then \( L = W'' \). So \( L \cap W'_\theta = 0 \), hence \( L \perp W'_\theta \). In other words all proper submodules of \( W'' \) are orthogonal to \( W'_\theta \), showing that their sum is still proper. Let \( Z \) denote this sum. Then \( W'' \cap Z^\perp \) is an irreducible submodule of \( W'' \).

This proves the existence of irreducible submodules of \( V \). Let \((V_i)\) be a maximal family of mutually orthogonal irreducible submodules of \( V \). If \( Y := \oplus_i V_i \neq V \), then \( Y^\perp \) will contain an irreducible submodule, contradicting the maximality of \((V_i)\). Hence the lemma.

**Corollary 2.6.** Let the notation be as above. If \( V \) is finitely generated, then \( V \) is an orthogonal direct sum of finitely many irreducible submodules.
Proof. Each generator lies in a finite sum of the \( V_i \). Since there are only finitely many generators, the corollary follows.

We are now ready to prove our main result for this section.

**Proof of Theorem 1.2** Since \( g_0 \) leaves invariant \( V_0, V_1 \) separately, \( \pi_0 \) can be constructed separately on the closures of \( V_0 \) and \( V_1 \), by the Theorem 2.1 in Subsec. 2.1 and so the full \( \pi_0 \) is even. We know that \( V \subset C^\omega(\pi_0) \), again by Theorem 2.1. Theorem 1.1 of Sec. 1 now proves the present theorem.

**Remark 2.7.** In the special case of highest weight modules, the proof of unitarizability is simpler. In view of our corollary to Lemma 2.2, it is enough to show, besides (U1) and (U2), only that the \( V \) are highest weight modules for \( g_0 \), because the conditions in Cor. 2.6 are automatically verified (see [19] Ch. 8).

2.3. **Construction of Harish-Chandra modules for** \((g, \mathfrak{t})\). Apart from the highest weight modules we have not produced any other Harish-Chandra modules (see [5]). In this section we do precisely this. We need some preliminary remarks.

Let \( M \) be a Harish-Chandra module for \( g_0 \) and define \( V := \mathcal{U}(g) \otimes_{\mathcal{U}(g_0)} M \).

By Poincaré-Birkhoff-Witt theorem, if \( X_1, X_2, \ldots, X_r \) is a basis for \( g_1 \), and \( L \) is the span of all the \( X_{i_1} \ldots X_{i_m} \) where \( i_1 < \ldots < i_m \), \( m \leq r \), then \( \mathcal{U}(g) = L \mathcal{U}(g_0) \). Although \( g_1 \) is stable under \( \text{ad}(g_0) \), this is not true of \( L \). Let \( R \) be the linear span of all monomials \( X_{i_1} \ldots X_{i_m} \) where the \( i \)'s are not ordered and satisfy only \( 1 \leq i_1, i_2, \ldots, i_m \leq r, m \leq r \). Then \( R \) is finite dimensional, stable under \( \text{ad}(g_0) \), graded, and \( R \mathcal{U}(g_0) = \mathcal{U}(g) \). Hence

\[
\mathcal{U}(g) \otimes_{\mathcal{U}(g_0)} M = R \otimes_{\mathcal{U}(g_0)} M.
\]

The action of \( \mathcal{U}(g) \) on \( V \) is by the left on the first factor. Since \( R \) is \( \text{ad}(g_0) \)-stable, the action of \( g_0 \) is the tensor product of the adjoint action on \( R \) and the action on \( M \). We recall a well known result. If \( p, q, r \) are three irreducible representations of \( \mathfrak{t} \), we write \( p < q \otimes r \) if \( p \) occurs in \( q \otimes r \). Then:

\[
p < q \otimes r \iff r^* < q \otimes p^*
\]

where \( a^* \) is the dual representation of \( a \). This follows from the fact that \( p < q \otimes r \) if and only if \( q \otimes r \otimes p^* \) contains the trivial representation, and hence if and only if \( r^* < q \otimes p^* \).

**Proposition 2.8.** Let \( M \) be a Harish-Chandra module for \( g_0 \). Then \( V := \mathcal{U}(g) \otimes_{\mathcal{U}(g_0)} M \) is a Harish-Chandra module for \( (g, \mathfrak{t}) \).

**Proof.** We must show that for any irreducible class \( p \) of \( \mathfrak{t} \), \( \dim(V_p) < \infty \). Let \( r_1, \ldots r_t \) be the irreducible classes in \( R \). \( M \) is the direct sum of the \( M_q \) for the various irreducible classes \( q \) of \( \mathfrak{t} \), and we know that \( \dim(M_q) < \infty \) for all \( q \). Now, by our remark above, \( p \) occurs in \( r \otimes q \) if and only if \( q^* < r \otimes p^* \). Taking \( r = r_1, \ldots, r_t \) and fixing \( p \), this gives only finitely many choices for \( q \). Let \( Q \) be the finite set of \( q \) such that \( q^* < r_j \otimes p^* \) for some \( j = 1, 2, \ldots, t \). Hence

\[
V_p \subset R \otimes_{q \in Q} M_q
\]
showing that $\dim(V_p) < \infty$. □

**Remark 2.9.** By a slight variation of the argument in the Lemma 2.5 we can show that $V$ has subquotients which are irreducible. Starting with a module $M$ for which the weight spaces are not all finite dimensional, one of the subquotients of a finite composition series for $V$ will have this property and so will not be a highest weight module. These modules were studied in [7, 8] for ordinary Lie algebras and the above theory allows us to build non highest weight Harish-Chandra modules for Lie superalgebras. We plan to explore this further in a forthcoming paper.

### 3. Infinitesimal Unitarity

#### 3.1. Harish-Chandra homomorphism.

Let $\mathfrak{g}_C$ be a contragredient complex Lie superalgebra (see [14]). The Harish-Chandra homomorphism

$$\beta : Z(\mathfrak{g}_C) \to S(\mathfrak{h}_C)^W$$

identifies the center $Z(\mathfrak{g}_C)$ of the universal enveloping algebra with the subalgebra $I(\mathfrak{h}_C)$ of $S(\mathfrak{h}_C)^W$ (see [13]):

$$I(\mathfrak{h}_C) = \{ \phi \in S(\mathfrak{h}_C)^W \mid \phi(\lambda + t\alpha) = \phi(\lambda), \forall \lambda \in \langle \alpha \rangle^\perp, \alpha \text{ isotropic}, \forall t \in \mathbb{C} \}$$

For any $\mu \in \mathfrak{h}^*_C$, let $\mathcal{U}[\mu]$ be the subspace of $\mathcal{U}(\mathfrak{g}_C)$ given by

$$\mathcal{U}[\mu] = \{ a \in \mathcal{U}(\mathfrak{g}_C) \mid [H, a] = \mu(H)a \quad \forall H \in \mathfrak{h}_C \}.$$ 

Then $\mathcal{U}[0]$ is a subalgebra, $Z(\mathfrak{g}_C) \subset \mathcal{U}[0]$, and $(\mathcal{U}[\mu])$ is a grading of $\mathcal{U}(\mathfrak{g}_C)$; moreover $\mathcal{U}[\mu] \neq 0$ if and only if $\mu$ is in the $\mathbb{Z}$-span of the roots. If $\gamma_1, \ldots, \gamma_t$ is an enumeration of the positive roots, $\Delta^+ = \{ \gamma_1, \ldots, \gamma_t \}$ and $(H_i)$ is a basis for $\mathfrak{h}_C$, then elements of $\mathcal{U}[0]$ are linear combinations of monomials:

$$X_{-\gamma_1}^{p_1} \cdots H_1^{c_1} \cdots X_{\gamma_t}^{n_t}$$

with $(p_1 - n_1)\gamma_1 + \cdots = 0$. It is then clear that every term occurring in such a linear combination must necessarily have some $p_i > 0$ except those that are just monomials in the $H_i$ alone. So for any $u \in \mathcal{U}[0]$ we have an element $\beta(u) \in \mathcal{U}(\mathfrak{h}_C)$ such that

$$u \cong \beta(u)(\text{mod} \mathcal{P}), \quad \mathcal{P} = \sum_{\gamma > 0} \mathcal{U}(\mathfrak{g}_C)\mathfrak{g}_\gamma, \quad \gamma \in \Delta^+$$

Let $\lambda \in \mathfrak{h}^*_C$. The action of $u$ on the Verma module $V_\lambda$ must leave the weight spaces stable since it commutes with $\mathfrak{h}_C$, and so applying it to the highest weight vector $v_\lambda$ we see that $uv_\lambda = \beta(u)(\lambda)v_\lambda$ where we are identifying $\mathcal{U}(\mathfrak{h}_C)$ with the algebra of all polynomials on $\mathfrak{h}_C$, so that $\beta(u)(\lambda)$ makes sense. It follows from this that if $u \in \mathcal{U}(\mathfrak{h}_C) \cap \mathcal{P}$ then $u(\lambda) = 0$ for all $\lambda$ and so $u = 0$, i.e., $\mathcal{U}(\mathfrak{h}_C) \cap \mathcal{P} = 0$. Hence $\beta(u)$ is uniquely determined by the equation (3).

We extend the homomorphism $\beta : \mathcal{U}[0] \to \mathcal{U}(\mathfrak{h}_C)$ to a linear map $\mathcal{U}(\mathfrak{g}_C) \to \mathcal{U}(\mathfrak{h}_C)$ by making it 0 on $\mathcal{U}[\mu]$ for $\mu \neq 0$.
3.2. Hermitian forms. Let $V$ be a complex super vector space. An hermitian form on $V$ is a complex valued sesquilinear form $(,)$ (linear in the first, antilinear in the second argument) such that:

$$\langle u, v \rangle = (-1)^{|u||v|}\overline{\langle v, u \rangle}, \quad \forall u, v \in V$$

and $(u, v) = 0$ for $|u| \neq |v|$, where $|u|$ denotes the parity of an homogeneous element $u \in V$ (see [26] pg 111 and [9] Sec. 4). If $X$ is an endomorphism of $V$, we define its adjoint $X^*$ as

$$\langle Xu, v \rangle = (-1)^{|u||X|}\overline{\langle u, X^*v \rangle},$$

One can immediately verify that (see [26] pg 110):

$$\langle u, v \rangle = \begin{cases} i\langle u, v \rangle & |u| = |v| = 1 \\ (u, v) & \text{otherwise} \end{cases}$$

is an ordinary hermitian form. If $X^\dagger$ is the adjoint with respect to this ordinary hermitian form, we have that $X^* = i[X^\dagger].$ In fact, taking $|u| = |X| = 1$, $|v| = 0$, we have $\langle Xu, v \rangle = -\langle u, X^*v \rangle$ and

$$\langle Xu, v \rangle = -i\langle Xu, v \rangle = -i\langle u, X^\dagger v \rangle$$

A similar calculation is done if $|u| = 0$, and $|X| = |v| = 1$.

$(,)$ is an hermitian product on $V$ if $(,)$ and $i(,)$ are positive definite on $V_0$ and $V_1$ respectively, i.e. if the ordinary form $(,)$ is positive definite on $V$.

Let $V$ be a $\mathfrak{g}$ module, $\mathfrak{g}$ a real Lie algebra, via the representation $\pi$. $V$ (or $\pi$) is said to be unitary if there is an hermitian product $(,)$ for $V$ such that

$$\langle \pi(X)u, v \rangle = -(-1)^{|u||X|}\langle u, \pi(X)v \rangle \quad (u, v \in V, X \in \mathfrak{g}),$$

(see [26] pg 111). This implies:

$$\pi(X)^* = \begin{cases} -\pi(X), & |X| = 0 \\ +\pi(X), & |X| = 1 \end{cases} \quad \pi(X) = \begin{cases} -\pi(X), & |X| = 0 \\ -i\pi(X), & |X| = 1 \end{cases}$$

As one can readily check, this is equivalent to (U1), (U2) in Sec. 1 with (6) as hermitian product there. In fact, while condition (U1) regards the ordinary case, condition (U2) is expressed for $|X| = |u| = 1$ (similarly for $|X| = |v| = 1$) as:

$$\langle e^{-i\pi/4}\pi(X)u, v \rangle = \langle u, e^{-i\pi/4}\pi(X)v \rangle$$

that is:

$$\langle \pi(X)u, v \rangle = i\langle u, \pi(X)v \rangle$$

This implies the condition of unitarity to be $\pi(X)^\dagger = -i\pi(X)$, in agreement with (9).

Let $\mathfrak{g}$ be a real form of contragredient complex superalgebra $\mathfrak{g}_C$ and $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$ its Cartan decomposition. We assume $\mathfrak{g}_C$ to satisfy the equal rank condition:

$$\mathfrak{h}_C \subset \mathfrak{k}_C \subset \mathfrak{g}_C$$

for a fixed Cartan subalgebra $\mathfrak{h}_C$. Assume also that $\mathfrak{k}_C$ has a non trivial center. Then $\mathfrak{k}_C$ and $\mathfrak{p}_C$ decompose into the sum of root spaces and the root system of $\mathfrak{g}_C$ has
Lemma 3.2. Consists of even elements only and $\beta$ sequilinear: linear in the first and antilinear in the second argument. Notice that ordinary linear algebra (see [22]), this implies that $\langle w, z \rangle$ defines a semipositive definite supersymmetric sesquilinear form on $X$. It is uniquely determined by these requirements. We then can extend the unitary condition for a representation expressed in (8):

$$\langle \pi(X)u, v \rangle = (u, \pi(X)v) \quad X \in \mathcal{U}(\mathfrak{g}_C)$$

3.3. Unitary highest weight representations. We now wish to give a criterion for an highest weight representation of $\mathfrak{g}_C$ to be unitary. We shall follow closely [11].

**Lemma 3.1.** Let $\pi_\lambda$ be a unitary highest weight representation of $\mathfrak{g}_C$ of highest weight $\lambda$. Then $(-i)^{|a|} \beta(a^*a)(\lambda) > 0$ for all $a \in \mathcal{U}(\mathfrak{g}_C)$.

**Proof.** Let $v$ be the highest weight vector. It is not restrictive to assume $v$ to be even. By definition of $\beta$ we have:

$$(av, v) = \beta(a)(\lambda)(v, v), \quad a \in \mathcal{U}(\mathfrak{g}_C)$$

Hence:

$$0 < (-i)^{|a|} \beta(a^*a)(\lambda) \geq 0$$

which gives our claim, since $(v, v) = \langle v, v \rangle > 0$. \qed

To ease the notation let $\beta_\lambda(a) := \beta(a)(\lambda), a \in \mathcal{U}(\mathfrak{g}_C)$.

**Lemma 3.2.** Assume $(-i)^{|a|} \beta(a^*a) \geq 0$ for all $a \in \mathcal{U}(\mathfrak{g}_C)$. Then:

$$\langle w, z \rangle = (-i)^{|z||w|} \beta_\lambda(z^*w) \quad w, z \in \mathcal{U}(\mathfrak{g}_C)$$

defines a semipositive definite supersymmetric sesquilinear form on $\mathcal{U}(\mathfrak{g}_C)$, whose radical $R$ is a left ideal.

**Proof.** By [10] and by the definition of $\beta$ and $\ast$ we immediately have that $\langle \cdot, \cdot \rangle$ is sesquilinear: linear in the first and antilinear in the second argument. Notice that $\langle w, z \rangle = 0$ if $|z| \neq |w|$. In fact, if $|z| \neq |w|$, $|z^*w| = 1$, hence $z^*w \notin \mathcal{U}[0]$, which consists of even elements only and $\beta_\lambda$ is zero on $\mathcal{U}[\mu]$, for $\mu \neq 0$. Moreover since $(-i)^{|a|} \beta(a^*a)(\lambda) \geq 0$, we have that $\langle a, a \rangle \geq 0$, by [10]. By a standard argument in ordinary linear algebra (see [22]), this implies that $\langle a, b \rangle = \langle b, a \rangle, |a| = |b|$ and this concludes the first part of the proof.

Let $\mathcal{R}$ be the set of $z \in \mathcal{U}(\mathfrak{g}_C)$ with $\|z\| := \sqrt{\langle z, z \rangle} = 0$. If $z, z' \in \mathcal{R}$, that is $\|z\| = \|z'\| = 0$, by $\|z + z'\| \leq \|z\| + \|z'\|$, we immediately have that $\mathcal{R}$ is a subspace. Furthermore if $b^* = b'$, for $b, b' \in \mathcal{U}(\mathfrak{g}_C)$, we have:

$$\langle w, bz \rangle = (-i)^{|w||bz|} \beta_\lambda((bz)^*w) = \pm(-i)^{|w||b||z|} \beta_\lambda(z^*b^*w) = \pm(b'w, z)$$
Hence \( \|(w,bz)\| \leq \|bw\|\|z\| \). If \( z \in \mathcal{R} \), i.e. \( \|z\| = 0 \) and \( w = bz \), we get \( \|bz\| = 0 \), hence \( \mathcal{R} \) is a left ideal.

**Lemma 3.3.** Let the notation be as above. Assume \((-i)^{|a|}\beta_\lambda(a^*a) \geq 0 \) for all \( a \in \mathcal{U}(\mathfrak{g}_\mathbb{C}) \). Then \( \mathcal{U}(\mathfrak{g}_\mathbb{C})/\mathcal{R} \) is a unitary representation of \( \mathfrak{g}_\mathbb{C} \) with highest weight \( \lambda \).

**Proof.** One can check right away that \((,\) is well defined on \( \mathcal{U}(\mathfrak{g}_\mathbb{C})/\mathcal{R} \). To prove our claim, we need to show \( \mathcal{R} = M_\lambda \) the (unique) maximal ideal containing \( \mathcal{P}_\lambda = \sum_{\gamma \in \mathcal{P}} \mathcal{U}(\mathfrak{g}_\mathbb{C}) \mathfrak{g}_\mathbb{C}_\gamma + \sum_{\gamma \in \mathcal{P}} \mathcal{U}(\mathfrak{g}_\mathbb{C})(H_\gamma - \lambda(H_\gamma)1) \). We have \( \mathcal{P}_\lambda \subset \mathcal{R} \). They are both left ideals, so it is enough to show \( X_\alpha \in \mathcal{R} \) for \( \alpha > 0 \) and \( H_\gamma - \lambda(H_\gamma)1 \in \mathcal{R} \), the latter being an ordinary statement, so true for the ordinary theory. Notice that: \((X_\alpha,v) = \beta_\lambda(v^*X_\alpha) = 0 \) because of (3), hence \( X_\alpha \in \mathcal{R} \).

Now let \( \mathcal{M}' \) be a proper maximal ideal containing \( \mathcal{R} \). We want to show \( \mathcal{M}' = \mathcal{R} \). We first notice that it is stable under the \( \mathfrak{h}_\mathbb{C} \) action, in fact:

\[
[H,m] = Hm - m(H - \lambda(H)) - \lambda(H)m \in \mathcal{M}', \quad H \in \mathfrak{h}_\mathbb{C}, \quad m \in \mathcal{M}'
\]

By a standard fact, then also \( m_0 \), the \( \mathcal{U}[0] \) component of \( m \) is in \( \mathcal{M}' \). Then by (3) \( m_0 \equiv h \mod (\mathcal{P}) \) and \( h \equiv \beta_\lambda(h) \mod (\mathcal{P}_\lambda) \), so that \( m_0 \equiv \beta_\lambda(h) \mod (\mathcal{P}_\lambda) \) for some \( h \in \mathcal{U}(\mathfrak{h}_\mathbb{C}) (\mathcal{P} \subset \mathcal{P}_\lambda) \). Since \( \mathcal{P}_\lambda \subset \mathcal{R} \subset \mathcal{M}' \), we have \( \beta_\lambda(h) \in \mathcal{M}' \), and being a complex number, this tells that \( \beta_\lambda(h) = 0 \), otherwise \( \mathcal{M}' \) would not be a proper ideal. Hence, also \( \beta_\lambda(m_0) = \beta_\lambda(h) = 0 \). Now, let \( z \in \mathcal{M}' \). Since \( X_\alpha^* = c_\alpha X_{-\alpha} \) for any root vector \( X_\alpha \), \( \alpha \) a root of \( \mathfrak{g}_\mathbb{C} \) (see [9] Sec. 4), we have \( z^*z \in \mathcal{U}[0] \). Taking \( m_0 = z^*z \), for any \( z \in \mathcal{M}' \), this gives \((-i)^{|\lambda|}\beta_\lambda(z^*z) = (z,z) = 0 \), so \( \mathcal{M}' = \mathcal{R} \).

We are ready for the main result of this section.

**Proof of Theorem 3.3.** The first statement is immediate from the previous lemmas. The second statement comes from the ordinary result in [11] and easy calculations.

### 4. Irreducible Representations of \( \mathfrak{osp}_R(1|2) \)

#### 4.1. Introductory remarks.

We present here some calculations on highest weight Harish-Chandra modules for \( \mathfrak{g}_\mathbb{C} = \mathfrak{osp}_C(1|2) \) and the unitary ones of \( \mathfrak{g} = \mathfrak{osp}_R(1|2) \).

Let \( \mathbb{N} = \{0,1,2,\ldots\} \). We assume that \( t \notin \mathbb{N} \).

The Lie superalgebra \( \mathfrak{g}_\mathbb{C} \) consists of matrices

\[
\begin{pmatrix}
0 & \xi & \eta \\
\eta & a & b \\
-\xi & c & -a
\end{pmatrix}
\]

where \( \xi, \eta \) are complex odd variables, \( a, b, c \) complex even variables. The real form \( \mathfrak{g} \) consists of the real Lie superalgebra of matrices

\[
\begin{pmatrix}
0 & \xi & -i\xi \\
-i\xi & ia & b \\
-\xi & -b & -ia
\end{pmatrix}
\]

where the variables \( \xi, b \) are still complex, \( a \) is real, and bar denotes complex conjugation (see [11] Appendix A for notation).
The complex basis of $(\mathfrak{g}_C)_0 = \mathfrak{sl}(2)$ is the standard one $H = E_{22} - E_{33}, X = E_{23}, Y = E_{32}, E_{ij}$ denoting the elementary matrices (see [25] for notation). The complex basis for the odd part $(\mathfrak{g}_C)_1$ is $\{x, y\}$ where

$$x = E_{13} + E_{21}, \quad y = E_{12} - E_{31}.$$ 

For the real form, the even part has real basis $\{iH, X + Y, i(X - Y)\}$ and the odd part has real basis

$$x^* = -ix + y, \quad y^* = -x + iy.$$ 

4.2. Verma modules for $(\mathfrak{g}_C)_0$ with highest weight $t \not\in \mathbb{N}$. We recall here the ordinary theory. Let $W_t$ be the Verma module for $(\mathfrak{g}_C)_0$ of highest weight $t$. Then $W_t$ has basis $\{v_t, v_{t-2}, \ldots\}$ where $v_t \neq 0$, $Xv_t = 0$, $v_{t-2r} = Y_r v_t$. One knows that all the $v_{t-2r}$ are non zero, because of the identity:

$$XY^{r+1} = Y^{r+1}X + (r + 1)Y^r(H - r)$$

in $\mathcal{U}(\mathfrak{g}_C)_0$, established easily by induction on $r$. This shows that

$$Xv_{t-2(r+1)} = (r + 1)(t - r)v_{t-2r}.$$ 

Since $t \not\in \mathbb{N}$, the factor $(r + 1)(t - r)$ is non zero for any integer $r \geq 0$, it follows that if some $v_{t-2(r+1)} = 0$, then $v_{t-2r} = 0$, so that we eventually get $v_t = 0$. That this is irreducible already is seen because of (11). Indeed (11) shows that starting with any $v_{t-2r}$, we can reach $v_t$ by applying $X$ repeatedly. Thus the Verma modules $W_t$ are already irreducible. We now want to determine when the $W_t$ are unitary. By unitary we mean the existence of a hermitian product such that

$$(Zu, v) = -(u, Zv)$$

for all $Z$ in the real form of $\mathfrak{sl}(2)$, and $u, v \in W_t$, i.e., for $Z = iH, X + Y, i(X - Y)$. The main idea is to transfer the condition for unitarity to the complex Lie algebra $\mathfrak{sl}(2)$. For the Verma modules $W_t$, unitarity is equivalent to assuming that the $v_{t-2r}$ are mutually orthogonal and $X^* = -Y$ or $Y^* = -X$ or both. In fact, the condition is that $H^* = H, (X + Y)^* = -(X + Y), (X - Y)^* = X - Y$.

**Proposition 4.1.** $W_t$ is unitary if and only if $t$ is real and $t < 0$.

**Proof.** Recall that $t \not\in \mathbb{N}$. Let $W_t$ be unitary. Then $(v_{t-2}, v_{t-2}) = (Yv_t, v_{t-2}) = -(v_t, Xv_{t-2})$. But:

$$Xv_{t-2} = XYv_t = YXv_t + Hv_t = tv_t.$$ 

Hence $(v_{t-2}, v_{t-2}) = -t > 0$ if we normalize $(v_t, v_t) = 1$ (possible). Hence $-t > 0$. For the converse we must, when $t < 0$, define a unique hermitian product such that $(v_t, v_t) = 1$ and $X^* = -Y$. The $v_{t-2r}$ are to be mutually orthogonal and so we need to determine the $N(r) := (v_{t-2r}, v_{t-2r})$ inductively so that $X^* = -Y$ and all the $N(r) > 0$. The requirement $X^* = -Y$ forces the relation (by (11)):

$$(v_{t-2r}, v_{t-2r}) = (Yv_{t-2(r-1)}, v_{t-2r}) = -r(t - r + 1)(v_{t-2(r-1)}, v_{t-2(r-1)})$$

or

$$N(r) = -r(t - r + 1)N(r - 1), \quad N(1) = 1.$$
the second being the normalization \((v_t, v_t) = 1\). We define \(N(r)\) inductively by this and note that for \(t < 0\) we have \(N(r) > 0\) for all \(r\), since the factor \(-r(t - r + 1)\) is always \(> 0\) for \(r \geq 1\), as \(t < 0\). The hermitian product is now well defined and positive definite. It is now only a question of verifying that \(X^* = -Y\). For this we need only check \((Y v_{t-2(r-1)}, v_{t-2r}) = -(v_{t-2(r-1)}, X v_{t-2r})\) as all other hermitian products needed are zero. But the left hand side is \(N\) by definition of \(\text{Super Verma modules for}\ 4.3.

\textbf{Lemma 4.2.} Let \(t \not\in \mathbb{N}\) where \(\mathbb{N} = \{0, 1, 2, \ldots\}\) and let \(V_t\) be the \(\mathfrak{g}_C\) module with highest weight \(t\) and highest weight vector \(v_t\).

\textbf{Proof.} By Poincaré-Birkhoff-Witt theorem, \(\mathcal{U}(\mathfrak{g}_C) = \mathcal{U}(\mathfrak{g}_C)_0\{1, x, y, xy\}\). Hence

\[ V_t = \mathcal{U}(\mathfrak{g}_C)_0 v_t + \mathcal{U}(\mathfrak{g}_C)_0 v_{t-1}. \]

If \(v_{t-1} = 0\) then \(x v_t = y v_t = 0\), hence, as \(H = xy + yx\), we have \(H v_t = tv_t = 0\) showing that \(t = 0\). Also if \(X v_{t-1} \neq 0\), then it has weight \(t + 1\) which is impossible. The modules \(\mathcal{U}(\mathfrak{g}_C)_1 v_t, \mathcal{U}(\mathfrak{g}_C)_1 v_{t-1}\) are then highest weight non zero modules, of highest weights \(t, t - 1\). Hence, by our assumption that \(t \not\in \mathbb{N}\), they are Verma modules and irreducible. Note the sum is direct since \(H\) has disjoint spectra in the two pieces. Hence the result.

\textbf{Corollary 4.3.} Let the notation be as above. \(V_t\) has basis \(\{v_t, v_{t-1}, \ldots\}\) where \(v_{t-r} = y^r v_t\).

\textbf{Proof.} Recall that \(y^2 = -Y\). Given \(t \not\in \mathbb{N}\) there is only one structure of a super \(\mathfrak{g}_C\) module for \(W_t \oplus W_{t-1}\), namely the super Verma with highest weight weight \(t\). \(\square\)

\textbf{Lemma 4.4.} Let the notation be as above. In \(\mathcal{U}(\mathfrak{g}_C)\) we have

\[ xy^{2m} = y^{2m}x - my^{2m-1}, \quad xy^{2m+1} = -y^{2m+1}x + y^{2m}(H - m) \]

In particular, in \(V_t\),

\[ x v_{t-m} = c_m v_{t-m+1}, \quad c_{2m} = -m, \quad c_{2m+1} = t - m. \]

\textbf{Proof.} Since \(xy = -yx + H\) in \(\mathcal{U}(\mathfrak{g}_C)\), we have, by direct calculation, \(xy^2 = y^2x - y\) and \(xy^3 = -y^3x + y^2(H - 1)\). Hence the results are true for \(m = 1\). We use induction on \(m\). We have

\[ xy^{2m+2} = xy^{2m+1} = (-yx + H)y^{2m+1} = y^{2m+2}x - (m + 1)y^{2m+1} \]

and

\[ xy^{2m+3} = xy^{2m+2} = (-yx + H)y^{2m+2} = -y^{2m+3}x + y^{2m+2}(H - m - 1) \]

by direct calculation. The induction is complete. The formulae for \(V_t\) are immediate consequences by applying them to \(v_{t-m} = y^{t-m} v_t\). \(\square\)
4.4. **Unitary Super Verma modules for** $\mathfrak{g}_C$. The main idea now is to transform the condition for unitarity to the complex setting. For the ordinary Verma modules $W_t$, unitarity is equivalent to $X^* = -Y$ or $Y^* = -X$ or both. In fact, the condition is that $H^* = H$, $(X + Y)^* = -(X + Y)$, $(X - Y)^* = X - Y$. For supermodules we impose, following [3] and (U2) as in Sec. 4 the condition $\zeta Z$ is symmetric in the hermitian product where $\zeta = e^{-i\pi/4}$ (see [3]). As in the Verma case, we must convert this definition into a condition on the complex basis for $\mathfrak{g}_C$. The condition is that $\zeta x^\sim$, $\zeta y^\sim$ are symmetric (acting on the module) where $x^\sim = -ix + y$, $y^\sim = -x + iy$. This is the same as (see (3)):
\[
x^{\dagger} = -ix, \quad y^{\dagger} = -iy
\]
or
\[
ix^{\dagger} + y^{\dagger} = -x - iy, \quad -x^{\dagger} - iy^{\dagger} = ix + y.
\]
These are the same as
\[
x^{\dagger} = -y, \quad y^{\dagger} = -x
\]
or even just one of these relations, as the other follows by taking adjoints. Notice that for $u, v$ even $u^{\dagger} = u^*$ and $(u, v) = \langle u, v \rangle$, see Sec. 3.2 for the notation.

**Theorem 4.5.** $V_t$ is unitary if and only if $t$ is real and $t < 0$.

*Proof.* Recall that $t \not\in \mathbb{N}$. Let $V_t$ be unitary. Then
\[
xv_{t-1} = xv_t = -yv_t + Hv_t = tv_t
\]
So
\[
\langle v_{t-1}, v_{t-1} \rangle = \langle yv_t, v_{t-1} \rangle = -\langle v_t, xv_{t-1} \rangle = -t\langle v_t, v_t \rangle
\]
We can normalize $\langle v_t, v_t \rangle = 1$ so that we get $\langle v_{t-1}, v_{t-1} \rangle = -t$. Thus we must have $t < 0$. We now prove the converse. If $t < 0$ we must define a hermitian product on $V_t$ such that $x^{\dagger} = -y$.

The definition of the hermitian product goes as in the Verma case. The formulae for $c_m$ of Lemma 4.4 show that for $m \geq 1$, we see that $c_m < 0$ always. Let $N(r) = \langle v_{t-r}, v_{t-r} \rangle$. The relation $x^{\dagger} = -y$ forces the relation
\[
\langle v_{t-r}, v_{t-r} \rangle = \langle yv_{t-r+1}, v_{t-r} \rangle = -c_r\langle v_{t-r+1}, v_{t-r+1} \rangle
\]
or
\[
N(r) = -c_rN(r-1).
\]
We define $N(r)$ inductively with $N(0) = 1$. Then, as $-c_r > 0$, the $N(r)$ are defined and $> 0$ for all $r$. With the orthogonality of the $v_{t-r}$ this defines a hermitian product for $v_t$. To prove that $x^{\dagger} = -y$ in this hermitian product we need only check that $\langle xv_{t-r+1}, v_{t-r} \rangle = -\langle v_{t-r+1}, xv_{t-r} \rangle$. The left side in $N(r)$ while the right side is $-c_rN(r-1)$ and so we are done. \qed

**Remark 4.6.** We observe that the necessary conditions of Theorem 1.3 for $V$, chosen as in Theorem 4.5 to be unitary is satisfied, since we have only a non compact even root $\alpha$ and $\lambda(H_\alpha) = \lambda(H) = t < 0$.

*Proof of Theorem 1.4.* The first statement is Theorem 4.5. The second statement is an immediate consequence of the first statement and Theorem 1.2.
