(Received 19 September 2019; revised 12 May 2020; accepted 5 June 2020; published 10 July 2020)

A spin-U(1)-symmetry protected momentum-dependent integer-Z-valued topological invariant is proposed to time-reversal-invariant superconductivity whose nonzero value will lead to exactly flat surface band(s). The theory is applied to the weakly spin-orbit-coupled quasi-1D \( A_2Cr_3As_3 \) (\( A=\text{Na, K, Rb, Cs} \)) superconductors family with highest \( T_c \), up to 8.6 K with \( p_z \)-wave pairing in the \( S_z = 0 \) channel. It’s found that up to the leading atomic spin-orbit coupling (SOC), the whole (001) surface Brillouin zone is covered with exactly flat surface bands, with some of the regime hosting three flat bands and the remaining part hosting two. Such exactly flat surface bands will lead to a very sharp zero-bias conductance peak in the scanning tunneling microscopic spectrum. When a tiny subleading spin-flipping SOC is considered, the surface bands will only be slightly split. The application of this theory can be generalized to other unconventional superconductors with weak SOC, particularly to those with mirror-reflection symmetry.

I. INTRODUCTION

Topological superconductivity (TSC) has aroused great interest in past decades [1,2]. The key feature of TSC lies in the presence of gapless Majorana fermions at the end (for one dimension), edge (for two dimensions), or surface (for three dimensions) [3–17]. In one dimension, it is proposed that an effective \( p \)-wave superconductor realized via Rashba spin-orbit coupling (SOC) with Zeeman coupling [18] can accommodate Majorana end state, detected by the scanning tunneling microscope (STM) as a pronounced zero-bias conductance peak (ZBCP) [19]. However, in two or three dimensions, the dispersion of the Majorana bands on the edge or surface will broaden the bands and lead to weak [20–22] or no ZBCP [23,24] in the STM. Therefore, the experimental identification of TSC in higher than one dimension is still a challenge.

Here we investigate the evolution of the isolated end states of a one-dimensional (1D) \( p \)-wave superconductor when a weak imposed three dimensionality expands them into several branches of surface bands with dispersion. It is interesting to ask: is it possible to realize a quasi-1D TSC protected by some symmetries which hosts dispersionless surface band(s)? Here we propose a class of TSC protected by the time-reversal (TR) and the spin-U(1) symmetry (SUS), which hosts exactly flat surface band(s). Different from conventional nodal-line TSC [9,25–29], the flat surface band(s) here does not rely on the presence of the nodal line, and the whole surface Brillouin zone (BZ) can be covered by flat band(s), causing sharp ZBCP in the STM. Furthermore, we propose that the recently synthesized quasi-1D \( A_2Cr_3As_3 \) (\( A=\text{Na, K, Rb, Cs} \)) family [30–33] with predicted \( p_z \)-wave pairing symmetry [34,35] belongs to this TSC class, up to the leading SOC.

The low-energy degrees of freedom in the \( A_2Cr_3As_3 \) family are dominated by the Cr-3d orbitals [36,37], which are expected to be strongly correlated [34,35,38–40], supported by various experiments [41–45], implying an electron–interaction-driven pairing mechanism. Diverse experiments [30–32,41,42,46–50] have revealed unconventional pairing states, particularly with line nodes [31,46] and possibly triplet pairings [30–32] in the system. Symmetry analysis suggests that the leading SOC in the \( A_2Cr_3As_3 \) family is the atomic SOC conserving the SUS [34], and combined weak- and strong-coupling approaches have predicted time-reversal-invariant (TRI) \( p_z \)-wave triplet pairing with line nodes with the \( S_z = 0 \) component [34,35], belonging to the symmetry class required here up to the leading SOC.

In this paper, we provide a topological invariant associated with flat surface band(s) under combined TR+SUS symmetries for TSCs, and apply it to the quasi-1D \( A_2Cr_3As_3 \) family. As a result, the momentum-dependent topological invariant \( Z(k_x, k_y) \) for \( A_2Cr_3As_3 \) is nonzero all over the \( (k_x, k_y) \) plane, with different regimes covered with different \( Z \). Consequently, different regimes on the surface BZ are covered with...
different nonzero numbers of flat bands, causing sharp ZBCP in the STM. Our proposal provides smoking-gun evidence for experimental identification of such quasi-1D \( p_\text{-wave} \) superconductors as the \( \text{A}_2\text{Cr}_3\text{As}_3 \) with weak SOC conserving the SUS.

II. SUS PROTECTED TOPOLOGICAL INVARIANT

Let us consider a multiband TRI superconductor with SUS, whose Bogoliubov–de Gennes (BdG) Hamiltonian is

\[
H = \sum_{k\sigma} \varepsilon_{k\sigma} c_{k\sigma}^\dagger c_{k\sigma} + \sum_{k\beta} \left[ \Delta_{\alpha\beta}(k) c_{k\alpha}^\dagger \sigma'_{\beta\gamma}(k) + \text{H.c.} \right].
\]

Here \( \alpha, \beta = 1, \ldots, N_0 \) represent the band indices and \( \sigma \) labels spin. The TR symmetry requires \( \varepsilon_{k\sigma} = \varepsilon_{-k\sigma} \) and \( \Delta_{\alpha\beta} = \Delta_{\beta\alpha} \). This BdG Hamiltonian can be written in the particle-hole symmetric (PHS) four-component Nambu representation as

\[
H = \frac{i}{2} \sum_{k} \Psi_{k}^\dagger \mathcal{H}_{k} \Psi_{k}, \quad \mathcal{H}_{k} = \begin{pmatrix}
\varepsilon_{k} & 0 & 0 & \Delta_{k} \\
0 & -\Delta_{k}^T & -\varepsilon_{k} & 0 \\
0 & -\varepsilon_{k} & \varepsilon_{k} & 0 \\
\Delta_{k} & 0 & 0 & -\varepsilon_{k} \\
\end{pmatrix}.
\]

Here \( \varepsilon_{k} \equiv \text{diag}(\ldots, \varepsilon_{k\sigma}, \ldots) \). Note that the SUS requires the hopping blocks of the BdG matrix Eq. (2) to be diagonal and the pairing blocks to be block off-diagonal. The combined TRS and PHS lead to chiral symmetry, which enables us to do the unitary transformation \( H \rightarrow \tilde{H} = U^\dagger \mathcal{H} U \) to obtain an off-diagonal Hermitian matrix \( \tilde{H} \). Here the unitary matrix \( U \) and the upper-right off-diagonal block \( \tilde{H}_{12} \) of \( \tilde{H} \)

\[
U = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix},
\]

\[
\tilde{H}_{12} = \begin{pmatrix}
\varepsilon_{k} - i\Delta_{k} & 0 \\
0 & \varepsilon_{k} + i\Delta_{k} \\
\end{pmatrix}.
\]

Note that \( \tilde{H}_{12} \) is block diagonal, caused by the SUS.

Following the standard procedure introduced in Refs. [5,12,26], the so-called \( Q \) matrix is obtained:

\[
Q(k) = I - 2P(k) = \begin{pmatrix} q_1 & q_2 \\ q_1^\dagger & q_2^\dagger \end{pmatrix}.
\]

Here \( P(k) \) is the projection operator and the \( N_0 \times N_0 \) matrix \( q_1(q_2) \) is related to the upper-left (lower-right) block of \( \tilde{H}_{12} \) in Eq. (3), and hence the 1-4 (2-3) block of \( \tilde{H} \) in Eq. (2). Each block of the Hamiltonian only has the chiral symmetry and belongs to the AIII class, characterized by a Z topological invariant in 1D. The detailed formulas of \( q_1(q_2) \) are provided in Appendix A. Note that, in contrast with the cases in ordinary TRI superconductor [5,12,26], the extra SUS here makes the off-diagonal block \( q \equiv \text{diag}(q_1(q_2)) \) of the \( Q \) matrix block diagonalized into \( q_1(q_2) \) sub-blocks. This enables us to define the following two 1D winding number \( Z_{1/2} \) for the two sub-blocks \( q_1(q_2) \), instead of the one \( Z \) defined for the whole \( q \) for ordinary TRI superconductors [5,12,26]:

\[
Z_{1/2}(k_x, k_y) = \frac{i}{2\pi} \int_{-\pi}^{\pi} \text{tr}(q_{1/2}^\dagger \delta_{k_x} q_{1/2}) dk_z.
\]

Here, in defining the path-dependent 1D winding number \( Z_{1/2} \), we have chosen the path \( \gamma = \text{perimeter} \) [26] to be a vertical line passing \((k_x, k_y, 0)\). Note that due to the double counting brought about by the gauge redundancy in this representation, the physical topological invariant here should be \( Z_{1}(k_x, k_y) \), which leads to \([Z_1(k_x, k_y)]\) flat surface bands as shown in Appendix A. The relationship between the winding numbers \( Z \) and \( Z_{1/2} \) is similar to that between the Chern number and the spin Chern number [51,52].

It’s interesting to investigate the case of the intraband-pairing limit where \( \Delta_{k}^{zz} = \Delta_{k}^{\alpha\beta} \). In this case, it is proved in Appendix A that \( q_{1}(k) = \text{diag}(\ldots, e^{-ik_{0} z}, \ldots) \) with \( e^{-i\theta_{k}} = (\varepsilon_{k\sigma} - i\Delta_{k}^{\sigma\gamma})/|\varepsilon_{k\sigma} - i\Delta_{k}^{\alpha\beta}| \). Then, from Eq. (5), the winding number is obtained as

\[
Z_{1}(k_x, k_y) = \frac{i}{2\pi} \sum_{\alpha} \int_{-\pi}^{\pi} d\theta_{k\alpha} = \sum_{\alpha} t_{\alpha}(k_x, k_y).
\]

Equation (6) suggests that, in this limit, \( Z_{1}(k_x, k_y) \) is a summation of the contributions from each band \( \alpha \), with each contribution equal to the winding number of the complex phase angle of \( \varepsilon_{k\sigma} - i\Delta_{k}^{\sigma\gamma} \) along a closed path perpendicular to the \( k_z = 0 \) plane.

III. APPLIED TO \( \text{A}_2\text{Cr}_3\text{As}_3 \)

The point group of the quasi-1D \( \text{A}_2\text{Cr}_3\text{As}_3 \) family is \( D_{1h} \), which includes a \( C_{3z} \) rotation about the \( z \) axis and a mirror reflection about the \( xy \) plane. The low-energy band structure of \( \text{A}_2\text{Cr}_3\text{As}_3 \) can be well captured by a three-band tight-binding (TB) model \( H_{TB} \) in the absence of SOC [34], with the three relevant orbitals to be the \( 3d_{z^2}, 3d_{x^2-y^2}, \) and \( 3d_{x-y} \), respectively. From the symmetry analysis which is given in Appendix B, the leading SOC in this family takes the following on-site formula [34]:

\[
H_{SOC} = i\lambda_{so} \sum_{k\sigma} \sigma [c_{2\sigma}(k)c_{3\sigma}(k) - c_{3\sigma}(k)c_{2\sigma}(k)],
\]

which possesses the SUS required. We adopt \( \lambda_{so} \approx 10 \text{ meV} \) [34] below. Note that the mirror-reflection symmetry forbids spin-flipping on-site SOC, because each such term as \( c_{i\sigma\mu} c_{i\sigma\nu} \sigma g_{\mu\nu} \) would be changed to \( c_{i\sigma\mu} c_{i\sigma\sigma} \sigma g_{\mu\nu} = -c_{i\sigma\mu} c_{i\sigma\mu} \sigma g_{\mu\nu} \) under this symmetry operation as shown in Appendix B.

The FSs of the spin-up electrons shown in Fig. 1(a) consist of two 1D FSs named as \( \alpha \) and \( \beta \) and one 3D FS named as \( \gamma \). While each 1D FS contains two FS sheets nearly parallel to the \((k_x, k_y)\) plane, the 3D \( \gamma\)-FS intersects with the \((k_x, k_y)\) plane with their intersection line shown in Fig. 1(b). Note that the shape of the \( \gamma\)-FS is counterintuitive: it contains one connected large concave pocket centering around the \( \Gamma \) point, instead of three isolated small convex pockets centering around the \( M \) points. The FSs of the spin-down electrons are related to those of the spin-up electrons through the relation \( \varepsilon_{k\sigma} = \varepsilon_{-k\sigma} \uparrow \) brought about by the TRS, and the lack of inversion symmetry leads to \( \varepsilon_{-k\sigma} \neq \varepsilon_{k\sigma} \) and hence \( \varepsilon_{k\sigma} \neq \)
The paths Li intraband pairing, wherein Eq. (6) applies. Therefore, the A2Cr3As3 family are expected to belong to the paths part) in Fig. 1(b) are covered by pz symmetry of the system is TRI species do not coincide. The nontrivial topological invariant of A2Cr3As3 leads to 2 (3) flat bands over this regime on the surface BZ on each (001) surface.

IV. SURFACE SPECTRUM AND STM

The nontrivial topological invariant of A2Cr3As3 leads to flat surface bands. We have studied the edge spectrum of this system on the (001) surface as shown in Appendix C. The obtained energy spectrum as a function of kx and ky is shown in Fig. 2(a) along the high symmetric line, in comparison with the bulk band in the superconducting state shown in Fig. 2(b) with fixed kz = 0. To enhance visibility, the adopted pairing gap amplitudes are enhanced from realistic Δ1 ≈ 1 meV, Δ2 = Δ3 = 2 meV [34] for K2Cr3As3 with Tc ≈ 6 K to Δ1 = 20 meV, Δ2 = Δ3 = 40 meV. The comparison between Figs. 2(a) and 2(b) suggests that, in addition to the bulk continuum, some regime in the (kx, ky) plane is covered by an extra six flat bands, while the remaining regime is covered by extra four, with the boundary of the two regimes to be just the SC nodal lines shown in Fig. 1(b).
Fig. 2(a) are covered by 3 (2) flat bands on each surface BZ, consistent with the topological invariant calculations above.

The topological flat surface bands obtained above can be detected as the ZBCP in the site-dependent differential conductance spectrum $dI/dV$ of the STM. Details for the calculation of $dI/dV$ are provided in Appendix D. Figure 3(b) shows the $dI/dV \sim V$ curves for the end (red) and middle (black) points of the needlelike sample of the quasi-1D material, respectively. Obviously, there is a very sharp ZBCP in the spectrum of the end point, which is absent in that of the middle point.

V. SPIN-FLIPPING SOC

In real material of $\text{A}_2\text{Cr}_3\text{As}_3$, there can be weak subleading NN-spin-flipping SOC, whose explicit formula is given in Appendix B. This SOC term breaks the SUS, and the topological invariant Eq. (5) does not apply. However, this NN-SOC for the 3d orbitals is so weak (with strength $\lambda_{1/2} = 2$ meV) adopted that the above obtained flat bands are only slightly split, as shown in Fig. 4(a) and its zoom-in in Fig. 4(b). As a result, the sharp ZBCP is still present in the STM spectrum shown in Fig. 4(d).

Remarkably, even the spin-flipping SOC breaks the SUS here; there is still a narrow but finite regime in the BZ covered by a pair of exactly flat bands, as highlighted by the red oval in Fig. 4(b). This pair of exactly flat bands are protected by the topological invariant for conventional TRI SC without SUS [5,12,26]. As introduced above, for sufficiently weak $\lambda_{1/2}$, $Z(k_x, k_z) = Z_1(k_x, k_z) + Z_2(-k_x, -k_z)$. As the $\text{A}_2\text{Cr}_3\text{As}_3$ family is noncentrosymmetric, the weak difference between $\epsilon_{k_{0z}}$ and $\epsilon_{-k_{0z}}$ caused by Eq. (7) leads to weak noncentrosymmetry in $|Z_1(k_x, k_z)|$ and hence nonzero $Z(k_x, k_z) = \pm 1$ in the narrow shaded regime in Fig. 4(c), causing a pair of exactly flat surface bands there.

VI. DISCUSSION AND CONCLUSION

One may worry that the bad quality of the surface and the breaking of mirror-reflection symmetry there might hinder the detection of the surface states. The solution of these problems is shown in Fig. 4(e): when the tip of the STM is put on the side surface near the end of the sample within the localized length $\xi \approx 45c \approx 20$, there would be pronounced ZBCP in the spectrum, and when the tip is far from the end the ZBCP would vanish. Note that we can use the STM configuration adopted recently [53] to distinguish between the edge spectra of the $\text{A}_2\text{Cr}_3\text{As}_3$ and $\text{ACr}_3\text{As}_3$: while the former would exhibit the ZBCP, the latter with $s^\pm$ pairing [54] would not. Interestingly, the number of surface flat bands here can be easily tuned via doping as shown in Appendix E, readily tested by experiments.

The SUS-protected topological invariant proposed here also applies to other unconventional superconductors with weak SOC, particularly those with mirror-reflection symmetry proved in Appendix B, which maintains the SUS required here.

In conclusion, we have proposed an SUS protected momentum-dependent integer-Z valued topological invariant for TRI superconductors, whose nonzero value will lead to exactly flat surface bands. The projection of the bulk nodal line onto the surface BZ serves as a boundary across which the topological invariant changes $\pm 1$, which can be nonzero on both sides due to their integer-Z-valued character, distinguished from conventional topological nodal-line superconductors. Applying this theory to the $\text{A}_2\text{Cr}_3\text{As}_3$ family up to the leading SOC, we find that the whole (001) surface BZ is covered with exactly flat bands, which can be detected by the STM as sharp ZBCP. Probably, the band flattening on the surface might drive new instabilities to be detected. Our discovery not only reveals another type of TRI TSC, but...
it also provides smoking gun evidence for the experimental identification of the $p_\pm$-wave pairing symmetry of the quasi-1D $A_2\text{Cr}_3\text{As}_3$ family.

**APPENDIX A: TOPOLOGICAL INVARIANT**

In this section, we derive the spin-U(1)-symmetry (SUS) protected momentum-dependent integer-Z-valued topological invariant for time-reversal-invariant (TRI) superconductors, whose nonzero value will lead to exactly flat band(s) on the surface Brillouin zone.

We start from the following $N_\alpha$-band model:

$$H = \sum_{k_{\alpha\beta}} C_{k_{\alpha\beta}}^\dagger C_{k_{\alpha\beta}}^0 + \sum_{k_{\alpha\beta}} [C_{k_{\alpha\beta}}^{-\sigma} C_{k_{\alpha\beta}}^{+\sigma} + H.c.]$$

(A1)

Here $\alpha/\beta = 1, \ldots, N_\alpha$ denote the band indices. Note that here we have allowed SOC with SUS and interband pairing. From time-reversal symmetry (TRS), we obtain $\tilde{\varepsilon}_{k}^{\sigma} = \varepsilon_{-k_{\sigma}}$ and $\Delta(k) = \Delta^\dagger(k)$. We can rewrite $H$ into the formula of

$$H = \frac{1}{2} \sum_{k} (C_{k_{\sigma}}^+ C_{k_{\sigma}}^- C_{-k_{\sigma}}^- C_{-k_{\sigma}}^+) (H_{k}) (C_{k_{\sigma}}^- C_{k_{\sigma}}^+ C_{-k_{\sigma}}^+ C_{-k_{\sigma}}^-),$$

(A2)

with $C_{k_{\sigma}}^\pm = \cdots (C_{k_{\sigma\alpha}}^\pm) \cdots$, and

$$H_{k} = \begin{pmatrix} \varepsilon_{k_{\sigma}}^+ & 0 & 0 & \Delta_{k} \\ 0 & \varepsilon_{k_{\sigma}}^- & -\Delta_{k}^T & 0 \\ 0 & -\Delta_{k}^T & \varepsilon_{-k_{\sigma}}^- & 0 \\ \Delta_{k} & 0 & 0 & \varepsilon_{-k_{\sigma}}^+ \end{pmatrix}$$

(A3)

is a $4N_\alpha \times 4N_\alpha$ matrix. Here $\varepsilon_{k_{\sigma}}$ are the corresponding eigenvectors in the form of $(\varepsilon_{k_{\sigma}}, 0, 0, \varepsilon_{k_{\sigma}})$ with $\lambda$ to be the eigenvalue. Since

$$\det \begin{pmatrix} 0 & \varepsilon_{k_{\sigma}}^- - i\Delta_{k} \\ \varepsilon_{k_{\sigma}}^+ - i\Delta_{k} & 0 \\ 0 & 0 \\ \lambda \end{pmatrix} = 0,$$

(A8)

we have $\det(F^\dagger F - \lambda^2 I) = 0$. Because $F^\dagger F$ is a Hermitian operator with positive-definite eigenvalues, the obtained values of $\lambda$ are always positive-negative symmetrically distributed. Therefore, the 1-2 diagonal block of the $H_{k}$ in Eq. (A7) contributes $N_\nu$ negative eigenvalues and $N_\nu$ positive ones, respectively, with the corresponding eigenvectors in the form of $(\mu^T, \nu^T, 0, 0)^T$ and $(\mu^T, -\nu^T, 0, 0)^T$. Similarly, the 3-4 diagonal block of the $H_{k}$ in Eq. (A7) contributes the same number of negative and positive eigenvalues, with the corresponding eigenvectors in the form of $(0, 0, \mu^T, -\nu^T)^T$ and $(0, 0, \mu^T, \nu^T)^T$. Then, from Eq. (A6), the distribution of the eigenvalues of $H_{k}$ is similar, but with corresponding eigenvectors in the form of $(\mu^T, 0, \nu^T)^T$ and $(\mu^T, 0, -\nu^T)^T$. Following the standard procedure for the topological invariant of TRI SC [5,12], we evaluate the projection operator...
\[ \hat{\mathcal{P}} = \sum_{i=1}^{N_a} \begin{pmatrix} \mu_i^0 \\ v_i \\ 0 \\ \frac{1}{2} \end{pmatrix} \begin{pmatrix} \mu_i^0 \\ 0 \\ v_i \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ \mu_i^0 \\ 0 \\ v_i^\dagger \end{pmatrix} \begin{pmatrix} 0 \\ \mu_i^0 \\ 0 \\ v_i^\dagger \end{pmatrix} \begin{pmatrix} 0 \\ \frac{1}{2} \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ -\frac{q_i}{2} \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ \frac{1}{2} \end{pmatrix} \begin{pmatrix} 0 \\ -\frac{q_i}{2} \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ \frac{1}{2} \end{pmatrix}. \] (A10)

Here \((\frac{q_i}{2})_0^0\) (and \((\frac{q_i}{2})_0^0\)) \((i = 1, \ldots, N_a)\) are the \(2N_a\) eigenvectors of Eq. \((A5)\) with negative eigenvalues:

\[ \tilde{H}_k \begin{pmatrix} \mu_i^0 \\ 0 \\ 0 \\ v_i^\dagger \end{pmatrix} = E_i(k) \begin{pmatrix} \mu_i^0 \\ 0 \\ 0 \\ v_i^\dagger \end{pmatrix}, \quad E_i(k) < 0. \] (A11)

The formulas of \(q_1, q_2\) are:

\[ q_1 = -2 \sum_{i=1}^{N_a} \mu_i v_i^\dagger, \]

\[ q_2 = -2 \sum_{i=1}^{N_a} \mu_i^0 v_i^\dagger. \] (A12)

Here we have used the relation \(\sum_{i=1}^{N_a} \mu_i \mu_i^0 + \sum_{i=1}^{N_a} \mu_i \mu_i^0 = I \to \sum_{i=1}^{N_a} \mu_i \mu_i^0 = I/2; \sum_{i=1}^{N_a} v_i v_i^\dagger + \sum_{i=1}^{N_a} (-v_i)(-v_i)^\dagger = I \to \sum_{i=1}^{N_a} v_i v_i^\dagger = I/2 \) and similarly \(\sum_{i=1}^{N_a} \mu_i^0 \mu_i^0 = I/2; \sum_{i=1}^{N_a} v_i^{\dagger} v_i = I/2\). Then the \(\hat{Q}\) operator is:

\[ \hat{Q} = 1 - 2 \hat{\mathcal{P}} = \begin{pmatrix} 0 & 0 & q_1 & 0 \\ 0 & 0 & 0 & q_2 \\ q_1 & 0 & 0 & 0 \\ 0 & q_2 & 0 & 0 \end{pmatrix}. \] (A13)

Note that \(\hat{Q}\) is \(2 \times 2\) block off-diagonal, and furthermore the off-diagonal block is block diagonal. Due to this property, the winding number can be defined as \(Z_{1/2}\), with:

\[ Z_{1/2}(k_x, k_y) = \frac{i}{2\pi} \int_{-\pi}^{\pi} \text{tr}(q_{1/2} \hat{\theta}_{k_x} q_{1/2}) dk_x. \] (A14)

Note that \(Z_1(k_x, k_y)[\{\epsilon_k, \Delta_k\}] = Z_2(-k_x, -k_y)[\{\epsilon_k, \Delta_k^\dagger\}].\)

For nontrivial \(Z_{1/2}(k_x, k_y) \neq 0\), there will be \([Z_1] + [Z_2]\) zero modes at the momentum \((k_x, k_y)\) on the surface Brillouin zone in the above four-component Nambu representation \((A2)\). However, the gauge redundancy in this representation brings up double counting on the number of zero modes for each momentum. In fact, due to the SUS here, one can also write the BdG Hamiltonian in the gauge-redundancy-free two-component Nambu representation as \(H = \sum_k \psi_k^\dagger h \psi_k\), with \(\psi_k = (C_k^c, -C_k^c)\), and \(h\) is equal to the 1-4 block of Eq. \((A3)\). In this representation, the number of zero modes at momentum \((k_x, k_y)\) is \([Z_1(k_x, k_y)]\), and the other \([Z_2(k_x, k_y)]\) zero modes obtained in the four-component representation are just those folded from the momentum \((-k_x, -k_y)\) artificially in that representation, which is a double counting. Therefore, the physical topological invariant here is \(Z_1(k_x, k_y)\), which leads to \([Z_1(k_x, k_y)]\) flat surface bands.

In the following, we consider the special case of the intraband pairing limit, which is the case of most of the existing superconductors. Let us set \(\Delta^0(k) = \Delta^0(k)\delta_{q,0}\) and perform the calculations provided by Eqs. \((A5)\), \((A13)\), and \((A15)\). As a result, we obtain:

\[ q_1 = \text{diag}(e^{-i\theta_{k_1}}, e^{-i\theta_{k_2}}, \ldots, e^{-i\theta_{k_N}}), \]

\[ q_2 = \text{diag}(e^{-i\theta_{k_1}}, e^{-i\theta_{k_2}}, \ldots, e^{-i\theta_{k_N}}), \] (A15)

with:

\[ e^{-i\theta_{k_i}} = (\epsilon_{k_i}^\dagger - i\Delta_{k_i}^0)/|\epsilon_{k_i}^\dagger - i\Delta_{k_i}^0|, \]

\[ e^{-i\theta_{k_i}} = (\epsilon_{k_i}^\dagger - i\Delta_{k_i}^\dagger)/|\epsilon_{k_i}^\dagger - i\Delta_{k_i}^\dagger|. \] (A16)

Then, from Eq. \((A17)\), we evaluate the topological invariant \(Z_{1/2}(k_x, k_y)\) as:

\[ Z_{1/2}(k_x, k_y) = \frac{i}{2\pi} \int_{-\pi}^{\pi} \text{tr}(q_{1/2} \hat{\theta}_{k_x} q_{1/2}) dk_x = \frac{i}{2\pi} \sum_{a=1}^{N_a} \int_{-\pi}^{\pi} \hat{\theta}_{k_x} \text{tr}(q_{1/2} q_{1/2}) dk_x = \frac{1}{2\pi} \sum_{a=1}^{N_a} \int_{-\pi}^{\pi} \hat{\theta}_{k_x} \text{tr}(q_{1/2} q_{1/2}) dk_x. \] (A17)

Equation \((A17)\) suggests that, in the intraband pairing limit, \(Z_{1/2}(k_x, k_y)\) is a summation of the contributions \(I_a\) from each band \(a\), with each contribution \(I_a\) equal to the winding number of the complex phase angle of \(\delta_{k_x} + i\Delta_{k_x}^0\) along a closed path perpendicular to the \(k_z = 0\) plane.

**APPENDIX B: FORMULA OF SOC IN THE \(A_2Cr_3As_3\) FAMILY**

The \(A_2Cr_3As_3\) family are quasi-1D superconductors consisting of alkali-metal-atom-separated \([Cr_3As_2]_{\infty}\) double-walled subnanotubes extending along the easy axis, defined as the \(z\) axis here. The point group of the material is \(D_{3h}\), which includes a \(C_3\) rotation about the \(z\) axis and a mirror reflection \(M\) about the \(xy\) plane. The low-energy degrees of freedom of the material are the \(Cr-3d\) orbitals, which include the \(d_{z^2}\) (orbital 1), the \(d_{xy}\) (orbital 2), and the \(d_{x^2−y^2}\) (orbital 3).

Due to the \(D_{3h}\) point group and the time-reversal-symmetry (TRS), our system with the three low energy \(d\) orbitals has the following symmetry operators.

1. The time-reversal operator \(\hat{T}\):

\[ \hat{T} : \quad C_{i\uparrow} \rightarrow C_{i\downarrow}, \quad C_{i\downarrow} \rightarrow -C_{i\uparrow}. \] (B1)

2. The mirror-reflection operator \(\hat{M}\):

\[ \hat{M} : \quad C_{i\uparrow} \rightarrow C_{i\uparrow}, \quad C_{i\downarrow} \rightarrow -C_{i\downarrow}, \] (B2)
with \[ \mathbf{i}' = \hat{\mathbf{M}} \mathbf{i}. \]  

(3) The 120° rotation \( \hat{C}_3^1 \):  
\[ \hat{C}_3^1 : \quad C_{i\mu\sigma} \to C_{i\nu\sigma} D^{(1)}_{\mu\nu} e^{-i\sigma \pi/3}, \]  
with  
\[ D^{(1)}_{\mu\nu} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \\ 0 & \frac{-1}{\sqrt{3}} & \frac{-1}{\sqrt{3}} \end{pmatrix}. \]  

(4) The 240° rotation \( \hat{C}_3^2 \):  
\[ \hat{C}_3^2 : \quad C_{i\mu\sigma} \to C_{i\nu\sigma} D^{(2)}_{\mu\nu} e^{-2i\sigma \pi/3}, \]  
with  
\[ D^{(2)}_{\mu\nu} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & \frac{-1}{\sqrt{2}} \\ 0 & \frac{-1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix}. \]  

These symmetries bring constraint on the formula of SOC in the system. In the following, we first evaluate possible SOC conserving the SUS in (A), and then evaluate possible spin-flipping SOC in (B).

1. Formula of spin-U(1)-symmetric SOC

In this subsection, we analyze possible SOC terms with SUS, including the on-site formulas in \( a \) and the NN ones in \( b \).

a. Formula of on-site SOC conserving SUS

The on-site SOC with SUS can generally be written as  
\[ C_{i\mu\sigma} \to C_{i\nu\sigma} D^{(1)}_{\mu\nu} g_{\mu\nu} + C_{i\mu\sigma} D^{(2)}_{\mu\nu} g_{\mu\nu}. \]  
We consider possible spin-flipping on-site SOC with SUS conserving the \( \mu\nu \)-matrix to be Hermitian. Note that the TRS has been considered here. Let us evaluate possible SOC conserving the SUS in (A), and then evaluate possible spin-flipping SOC in (B).

b. Formula of NN-SOC with SUS

The combined TRS represented by Eq. (B1), the mirror symmetry represented by Eq. (B2), and the Hermitian character of the Hamiltonian require that the NN-SOC conserving the SUS takes the formula of  
\[ C_{i\mu\nu} g_{\mu\nu} \quad (i = 1, 2, 3); \]  
with  
\[ g_{\mu\nu} = \begin{pmatrix} g_{11} & 0 & 0 \\ 0 & g_{22} & -i \gamma \\ 0 & i \gamma & g_{22} \end{pmatrix}. \]  

Note that the weak diagonal term can be incorporated into the on-site chemical potential term, which will be ignored here. As a result, we get the Hamiltonian term describing this SOC,  
\[ H_{\text{SOC}} = i \lambda_3 \sum_i \sigma (C_{i2\sigma} C_{i3\sigma} - C_{i3\sigma} C_{i2\sigma}). \]  

It can be checked that this Hamiltonian satisfies all the symmetries listed above.

2. Formula of spin-flipping SOC

In this subsection, we analyze possible spin-flipping SOC terms breaking SUS, including the on-site formulas in 1 and the NN ones in 2.

a. Formula of spin-flipping on-site SOC

It is proved here that the mirror-reflection symmetry \( M \) will forbid spin-flipping on-site SOC.

Actually, assuming we have a spin-flipping SOC term in the form of  
\[ C_{i\mu\nu} g_{\mu\nu} \quad (i = 1, 2, 3), \]  
with  
\[ g_{\mu\nu} = \begin{pmatrix} g_{11} & 0 & 0 \\ 0 & g_{22} & -i \gamma \\ 0 & i \gamma & g_{22} \end{pmatrix}. \]  

When considering the possible spin-flipping SOC conserving the SUS, we have  
\[ C_{i\mu\nu} g_{\mu\nu} \quad (i = 1, 2, 3); \]  
with  
\[ g_{\mu\nu} = \begin{pmatrix} g_{11} & 0 & 0 \\ 0 & g_{22} & -i \gamma \\ 0 & i \gamma & g_{22} \end{pmatrix}. \]  

The mirror-reflection symmetry \( M \) will forbid spin-flipping on-site SOC.

b. Formula of spin-flipping NN-SOC

Here we evaluate the possible NN-spin-flipping SOC term. From the combination of the TRS represented by Eq. (B1), the mirror symmetry represented by Eq. (B2), and the Hermitian character of the Hamiltonian, such SOC term takes the following general formula:  
\[ H_{\text{flip-SOC}} = \sum_{i\mu\nu} C_{i\mu\nu} g_{\mu\nu} - C_{i\mu\nu} g_{\mu\nu}. \]  

This Hamiltonian is already Hermitian.

Then the \( C_3^1 \)-rotation symmetry represented by Eq. (B4) leads to the equation  
\[ D^{(1)}_{\mu\nu} g D^{(1)}_{\mu\nu} = g e^{i \pi \gamma}. \]

This equation can be solved as  
\[ g = \begin{pmatrix} 0 & i \lambda_1 & 0 \\ i \lambda_1 & \lambda_2 & i \lambda_2 \\ 0 & i \lambda_2 & -\lambda_2 \end{pmatrix}, \]

where \( \lambda_1 \) and \( \lambda_2 \) are two independent coupling constants.
Therefore, the symmetry-allowed NN-spin-flipping SOC term in the $A_2$Cr$_3$As$_3$ family takes the form of Eq. (B12), with the symmetric $g$ matrix provided by Eq. (B14).

**APPENDIX C: SURFACE SPECTRUM**

To calculate the surface spectrum, we first need a real-space BCS-MF Hamiltonian. For the pairing gap function introduced in the main text, only the $k$-space gap function on the FS is provided, and thus we need a real-space pairing potential. Actually, the pairing state in K$_2$Cr$_3$As$_3$ can be approximately generated by the following MF Hamiltonian including only nearest-neighbor (NN) intraorbital pairing potential [34]:

$$H = H_{TB} + H_{SOC} + H_{\Delta},$$

$$H_{\Delta} = \sum_{i\mu} \left[ (c_{i\mu\uparrow}^\dagger c_{i+1\mu\downarrow} + c_{i\mu\downarrow}^\dagger c_{i+1\mu\uparrow}) \Delta_{\mu} + H.c. \right]. \quad (C1)$$

This pairing state has a weak interband pairing component and its intraband pairing component is well consistent with that obtained by the RPA approach. The topological invariants for this pairing state yield exactly the same results as those of the RPA.

In the following, we adopt two different approaches to calculate the surface spectrum of the system described by Eq. (C1) in the presence of SUS or Rashba SOC. In the first approach, we directly diagonalize the Bogoliubov–de Gennes Hamiltonian of the superconducting system using a slab geometry with open boundary condition along the $z$ axis (the width is 200$\text{c}$) and periodic ones along the $x$ or $y$ axis and (b) the iterative Green’s function approach for K$_2$Cr$_3$As$_3$ with SUS, respectively. The adopted $\Delta_1 = 20 \text{ meV}$ and $\Delta_2 = \Delta_3 = 40 \text{ meV}$ are enhanced by an order of magnitude over realistic ones to enhance the visibility. The on-site SUS SOC $\lambda_{so1} = 10 \text{ meV}$.

Therefore, the symmetry-allowed NN-spin-flipping SOC term along the $x$ or $y$ axis and (b) the iterative Green’s function approach for K$_2$Cr$_3$As$_3$ in the presence of spin-flipping SOC, respectively. Panels (c) and (d) are the zoom-in of (a) and (b). The parameters are taken as $\Delta_1 = 20 \text{ meV}$, $\Delta_2 = \Delta_3 = 40 \text{ meV}$, the on-site SUS SOC $\lambda_{so1} = 10 \text{ meV}$, the NN-SUS SOC $\lambda_{so2} = 2 \text{ meV}$, and the NN-spin-flipping SOC $\lambda_1 = \lambda_2 = 2 \text{ meV}$.

**APPENDIX D: STM**

The site-dependent differential conductance $dI/dV$ spectrum of the STM can be evaluated as

$$\rho(i_x, \omega) = \rho(i_x, i_y, i_z, \omega) = \frac{-\text{Im} \left[ \sum_{i\mu} |\langle \psi_{i,j,i\mu}^\dagger | H | \psi_{i,j,i\mu} \rangle |^2 \right]}{\omega - E + i0^+} \quad (D1)$$

$$= \frac{-2\text{Im} \left[ \sum_{i\mu} \langle \psi_{i,j,i\mu}^\dagger | H | \psi_{i,j,i\mu} \rangle \frac{\sqrt{N_x}}{E - E_m(k_x, k_y) + i0^+} \right]^2}{N_x N_y} \quad (D2)$$

where $N_x, N_y$ are the size of the lattice along $x$ and $y$ directions, $E_m(k_x, k_y)$ is the $m$th eigenvalue of the BdG Hamiltonian matrix for the fixed momentum $(k_x, k_y)$, and $\psi_{i,j,m}(k_x, k_y)$ is the corresponding eigenvector. Note that the spectrum only depends on $i_z$ and not on $i_x$ or $i_y$. The coordinates $i_z = 1(N_z)$ and $i_z = N_z/2$ correspond to the end and the middle of the sample, respectively.

**APPENDIX E: FERMI SURFACE EVOLUTION AND LIFFSHITZ TRANSITION UPON DOPING**

The FS topology of K$_2$Cr$_3$As$_3$ can be drastically changed upon slightly doping, accompanied by several Lifshitz transitions. The results obtained from both approaches agree well with each other, which exhibits the exactly flat surface spectra shown in Figs. 5 and 6.
transitions. As a result, the distribution of the number of topological flat surface bands will be easily engineered through doping, which can be detected by experiments. The FSs in both figures (Fig. 7 for hole doping and Fig. 8 for electron doping) are the FSs of the spin-up electrons, and the FSs for the spin-down channel can be obtained by time-reversal operation. Consistent with the topological invariant calculations in the main text, the corresponding areas in the surface spectrum of Figs. 7 and 8 are covered by two or three flat bands on the surface Brillouin zone.

FIG. 8. Same as Fig. 7 but for electron doping with Fermi energy $E_f = 6$ meV, 14 meV, 20 meV, and 45 meV, respectively.
