Enantioselective dearomative [3 + 2] cycloadditions of indoles with azomethine ylides derived from alanine imino esters†

Anthony L. Gerten and Levi M. Stanley*

Catalytic, enantioselective [3 + 2] cycloadditions of azomethine ylides derived from alanine imino esters with 3-nitroindoles are reported. The dearomative cycloaddition reactions occur in the presence of a catalyst generated in situ from Cu(OTf)2 and (R)-1,1-difluorophos to form exo-pyrroloindoline cycloadducts and establish four contiguous stereogenic centers, two of which are fully substituted. The exo-pyrroloindoline products are formed in moderate-to-good yields (39–85%) with high diastereoselectivities (up to 98 : 1 : 1 dr) and enantioselectivities (up to 96% ee).

Introduction

The development of dearomatization reactions offers the potential to rapidly generate molecular complexity and new molecular frameworks.1 In recent years, [2 + 2],2 [3 + 2],3 [4 + 2],4 and [5 + 2]5 dearomative cycloadditions have emerged as promising strategies to construct polycyclic carbocycles and heterocycles from arenes and heteroarenes. Despite the steady development of new dearomative cycloaddition reactions, examples of catalytic, enantioselective dearomative cycloadditions are limited.2a,3e–g,9–i

Among the promising classes of dearomative cycloadditions for further development are intermolecular [3 + 2] cycloadditions of nitrogen-containing 1,3-dipoles with arenes and heteroarenes. In particular, cycloadditions of azomethine ylides with arenes and heteroarenes have emerged as a viable approach to generate polycyclic nitrogen heterocycles.6 Gribble and co-workers initially reported cycloadditions of unstabilized azomethine ylides with 2- and 3-nitroindoles to form racemic pyrroloindolines.7 More recently, Chataingner, Piettre, and co-workers showed that cycloadditions of unstabilized azomethine ylides with electron-deficient arenes and heteroarenes form a wide variety of racemic, polycyclic cycloadducts in good-to-excellent yields.8

In 2014, Awata and Arai reported the first catalytic, enantioselective dearomative cycloadditions of stabilized azomethine ylides with 3-nitroindoles.9 Cycloadditions of a wide range of azomethine ylides derived from glycine imino esters occur with excellent enantioselectivity and nearly perfect exo-selectivity when the reactions are run in the presence of a complex prepared from Cu(OTf)2 and a chiral PyBidine ligand. However, catalytic, enantioselective dearomative cycloadditions of azomethine ylides derived from alanine imino esters have

Levi M. Stanley received his B.A. in chemistry from Augustana College (SD) in 2001, where he worked with Professors Gary Earl and Jetty Duffy-Matzner. In 2002, he began his graduate studies with Professor Mukund P. Sibi at North Dakota State University, where he developed enantioselective dipolar cycloadditions and studied applications of chiral relay ligands and auxiliaries in enantioselective catalysis. He received his Ph.D. in 2007 and joined professor John F. Hartwig's group at the University of Illinois as an NIH Postdoctoral Fellow. His work in the Hartwig group focused on the development of iridium-catalyzed allylic substitution reactions. In 2011, he joined the faculty at Iowa State University in the Department of Chemistry. Areas of research interest include catalysis, synthetic organic chemistry, and heterocyclic chemistry.
not been reported. Herein, we report the first examples of diastereo- and enantioselective dearomative cycloadditions of alanine-derived azomethine ylides with 3-nitroindoles. These reactions generate pyrroloindolines with four contiguous stereo-selective centers, two of which are fully substituted (Scheme 1).

Results and discussion

To identify a diastereo- and enantioselective catalyst for dearomative cycloadditions of alanine-derived azomethine ylides, we evaluated the model reaction of N-tosyl-3-nitroindole 1a with racemic imino ester 2a (Table 1). Initially, we found that copper(II) triflate complexes of the chiral bisphosphine ligands (R)-BINAP, (R)-Segphos, and (R)-Difluorphos (10 mol%) catalyzed the cycloadditions of 1a with 2a. These reactions formed a diastereomeric mixture of cycloadducts 3a with exo'-3a generated as the major diastereomer (entries 1–3). The reaction of 1a and 2a occurred with the highest diastereoselectivity (93 : 3 : 4 exo'-3a : exo-3a : endo-3a) with the copper(II) triflate complex of (R)-difluorphos as catalyst (entry 3).10 The cycloadduct exo'-3a was isolated in 73% yield with 86% ee. The high enantioselectivity and diastereoselectivity observed for the model reaction led us to explore additional reaction parameters using the combination of Cu(OTf)2 and (R)-difluorphos as catalyst.

By lowering the reaction temperature to 0 °C and −20 °C, we observed higher enantioselectivity for exo'-3a (92–93% ee) with lower diastereoselectivity (entries 4 and 5). For example, the reaction of 1a with 2a forms a 41 : 15 : 44 mixture of exo'-3a : exo-3a : endo-3a when the reaction is carried out at −20 °C. The endo selectivity of the reaction carried out at

<sup>a</sup> Reaction conditions: 1a (0.20 mmol), rac-2a (0.20–0.40 mmol), Cu(OTf)2 (0.02 mmol, 10 mol%), ligand (0.02 mmol, 10 mol%), DBU (0.04 mmol, 20 mol%), THF (1.0 mL), 14–18 h. <sup>b</sup>Determined by <sup>1</sup>H NMR spectroscopy of the crude reaction mixture. <sup>c</sup>Isolated yield of exo'-3a with >95 : 5 dr. <sup>d</sup>Determined by chiral HPLC analysis. <sup>e</sup>Reaction conducted with 5 mol% of the Cu catalyst.
–20 °C led us to postulate that the model cycloaddition is endo-selective, but epimerization of endo-3a to exo-′3a occurs at higher temperatures through a retro-Mannich/Mannich addition pathway and leads to the observed exo′-selectivity.11

Lowering the loading of the copper catalyst also proved detrimental to the diastereo- and enantioselectivity of the model reaction. The reaction of 1a with 2a in the presence of 5 mol% of the copper catalyst formed 3a as a 71 : 11 : 18 mixture of exo′ : exo : endo diastereomers with exo′-3a isolated in 76% ee (entry 6). The decrease in enantioselectivity and diastereoselectivity observed at lower catalyst loading suggests: (1) the rate of uncatalyzed background reaction is likely competitive with the rate of the catalyzed process; and (2) the copper complex may catalyze the epimerization of endo-3a to exo-′3a.

Varying the concentration of imino ester 2a has minimal impact on the yield and selectivity of the model reaction (compare entries 3 and 7–9). The diastereoselectivity remains essentially unchanged when varying the amounts of imino ester 2a from 1.0–2.0 equivalents. However, a slight excess (1.2 equivalents, entry 7) of 2a leads to a modest increase in enantioselectivity, but this trend does not hold when the concentration of 2a is further increased (entries 8 and 9).

To develop a better understanding of the rates of the catalyzed reaction and the uncatalyzed background reaction and the evolution of the diastereoselectivity over time, we conducted cycloadditions of 1a with 2a in the presence and absence of copper catalyst and monitored the yield and diastereoselectivity over time (Table 2). The catalyzed reaction of 1a with 2a occurs to approximately 90% conversion after 2 h (entry 1) and is complete after 6 h (entry 3), while the uncatalyzed reaction occurs to approximately 50% and 80% conversion over the same time periods (entries 2 and 4). Although the uncatalyzed background reaction is slower than the catalyzed process, this data shows that the rate of uncatalyzed cycloaddition is sufficient to negatively impact the enantioselectivity of the cycloadditions and likely explains the poor enantioselectivity observed when the catalyst loading is lowered.

The evolution of diastereoselectivity over time is greatly influenced by the presence or absence of the copper catalyst. The uncatalyzed model reaction forms a 59 : 6 : 35 ratio of exo′ : exo : endo diastereomers after 2 h, and this ratio does not change significantly over an additional 4 h (Table 2, entries 2 and 4). In contrast, the diastereoselectivity of the copper-catalyzed cycloaddition changes markedly with reaction time. The catalyzed reaction forms a 69 : 5 : 26 ratio of exo′ : exo : endo diastereomers after 2 h (entry 1); a ratio that is similar to that observed in the uncatalyzed reaction. However, the diastereomeric ratio improves to 77 : 9 : 14 (entry 3) after 6 h and to 93 : 3 : 4 (entry 5) after 16 h. The dramatic decrease in the amount of endo-3a and increase in the amount of exo′-3a indicates that the complex generated from Cu(OTf)2 and L3 catalyzes the epimerization of endo-3a to exo′-3a which leads to the high exo′ selectivity of the cycloaddition reaction.

With a practical set of reaction conditions and a diastereo- and enantioselective catalyst identified, we evaluated cycloadditions of N-tosyl-3-nitroindole 1a with a variety of imino esters 2b–k derived from alanine methyl ester and an array of aromatic aldehydes. Results of these reactions are summarized in Table 3. In general, cycloadditions of 1a with imino esters containing 4-substituted aryl groups occur to form exo-3 in >70% yield with >90% ee and >90 : 7 : 3 exo′ : exo : endo diastereoselectivity (entries 1–5). The notable exceptions to these typical yields and selectivities include the reactions of imino esters 2b (Ar = 4-FC6H4) and 2c (Ar = 4-ClC6H4). The cycloaddition of 2b with 1a occurs in high yield with excellent diastereoselectivity (entry 1). However, exo′-3b is isolated with 80% ee, possibly due to a faster rate of uncatalyzed background reaction with an azomethine ylide containing an electron-withdrawing 4-trifluoromethyl group on the arene moiety. This hypothesis is supported by a positive correlation between enantioselectivity of the reaction and increasing electron-donating ability of substituents at the 4-position on the aryl ring of the dipoles. The cycloaddition of 2c with 1a forms exo′-3b in 70% yield with 88% ee, but the reaction occurs with modest diastereoselectivity (entry 2).

Cycloadditions of imino esters 2g–k containing 2- and 3-substituted aryl groups with 1a generally occur with slightly lower yields and selectivities (entries 6–10) than imino esters 2b–f. While the cycloaddition of 3-MeO-substituted imino ester 2g occurs to form exo-3g in high yield with high diastereo- and enantioselectivity (entry 6), the cycloaddition of 3-Br-substituted imino ester 2h formed exo′-3h in only 40% yield with modest diastereoselectivity, likely due to a relatively slow epimerization of endo-3g to exo-3g, and slightly lower enantioselectivity (entry 7). Cycloadditions of 2-MeO, 2-F, and 2-Cl-substituted imino esters 2i–k formed exo′-3i–k in 39–85%
yield with 79–87% ee and with diastereoselectivities ranging from 67 : 5 : 27 to 88 : 8 : 4 \text{exo}^\prime : \text{exo} : \text{endo} (entries 8–10).

The absolute configuration of \text{exo}^\prime-3f was determined after treatment with HBr to form \text{exo}^\prime-3f-\text{HBr} in >99% yield (Scheme 2). The absolute configuration of \text{exo}^\prime-3f-\text{HBr} was determined to be (1S,3R,3aS,8bS) by X-ray crystallographic analysis.

Although our studies focused on reactions of N-tosyl-3-nitroindole 1a with imino esters derived from alanine methyl ester, we have also demonstrated that cycloadditions involving an imino ester derived from alanine isopropyl ester and \text{N-tosyl-5-bromo-3-nitroindole} occur in high yields with excellent stereoselectivity (Scheme 3). For example, the reaction of \text{N-tosyl-3-nitroindole} 1a with imino ester 2l derived from alanine isopropyl ester occurs with 93 : 7 \text{exo}^\prime : \text{exo} diastereoselectivity and forms pyrroloindoline \text{exo}^\prime-3l in 71% yield with 94% ee (Scheme 3a). The \text{endo} diastereomer was not observed after the 18 h reaction time. The cycloaddition of imino ester 2a with \text{N-tosyl-5-bromo-3-nitroindole} 1b occurs with nearly perfect \text{exo}^\prime selectivity (>98 : 1 : 1 \text{exo}^\prime : \text{exo} : \text{endo}, Scheme 2b).

Pyrroloindoline \text{exo}^\prime-3m was isolated in 79% yield with 91% ee.

Conclusions

In summary, we have developed the first catalytic, enantioselective dearomative cycloadditions of alanine-derived imino esters with 3-nitroindoles. These exo'-selective dearomative cycloadditions form a variety of highly enantioenriched pyrrolindolines with four contiguous stereogenic centers, two of which are fully substituted, when the reactions are conducted in the presence of a catalyst generated from Cu(OTf)$_2$ and (R)-difluorphos. The high diastereoselectivities observed favoring the formation of the exo'-cycloadduct result from a Cu(OTf)$_2$/ (R)-difluorphos-catalyzed epimerization of the endo'-cycloadduct to the exo'-cycloadduct during the course of the reaction. Studies to develop new catalytic, enantioselective dearomative cycloadditions with additional classes of aromatic and heteroaromatic dipolarophiles are ongoing in our laboratory.
