NEVANLINNA-PICK INTERPOLATION PROBLEM
IN THE BALL

LUKASZ KOSIŃSKI AND WŁODZIMIERZ ZWONEK

ABSTRACT. We solve a 3-point Nevanlinna-Pick problem in the Euclidean ball. In particular, we determine a class of rational functions that interpolate this problem.

1. Introduction

The Nevanlinna-Pick problem for a domain $D$ of $\mathbb{C}^n$ may be stated as follows: Given distinct points $z_1, \ldots, z_N$ in $D$ and numbers $\lambda_1, \ldots, \lambda_N$ in the unit disc $D$, decide whether there is an analytic function $F : D \to D$ that interpolates, i.e., $F(z_j) = \lambda_j$, $j = 1, \ldots, N$. The problem is very classical; its original version was stated for $D = \mathbb{D}$ and solved by Pick in 1916 (see [21]).

This problem has been considered in different domains, and many attempts have been made to extend it in different directions. In general, the analogue of Nevanlinna-Pick’s theorem does not hold for domains other than the disc. So far it is not clear how to get any solvability criterion for an arbitrary domain $D$. An important result towards understanding this problem was achieved by Sarason, who found deep relations between the Nevanlinna-Pick problem and several results in operator theory (see [23]). Cole, Lewis, and Wermer in [9] considered the problem for any uniform algebra. In a sequence of influential papers (see [2–5] and also a monograph [6]) Agler and McCarthy used the operator theory approach to carry out an analysis of the Nevanlinna-Pick problem for the bidisc. However, methods developed there did not work for any other domains. They even failed for higher dimensional polydiscs $D^n$. Some results for $D^n$ and the Euclidean ball $B_n$ were obtained by Hamilton [13]. Interpolation in the Euclidean ball was also investigated by Amar and Thomas [7, 8]. Recently, the first author of this paper found an alternate approach to the Nevanlinna-Pick problem in the polydisc (see [16]) and $N = 3$, which resulted in solving the problem in this situation. This approach also allowed Knese to prove the von Neumann inequality for $3 \times 3$ matrices (see [15]).

In our paper we adopt the methods from [16] to deal with the Nevanlinna-Pick problem for the Euclidean ball.

Roughly speaking we show that a 3-point Nevanlinna-Pick problem in the Euclidean ball may be expressed in terms of a dual problem $D \to B_n$. We also find a class of rational functions of degree at most 2 interpolating every such problem. Extremal functions in this class are, up to a composition with an automorphism of
2. Definitions and results

2.1. Interpolation problems. Extremal maps. The definitions we present here are taken from [17] and [24].

Let $D$ be a domain in $\mathbb{C}^n$ and let $N \geq 2$. Fix pairwise distinct points $\lambda_1, \ldots, \lambda_N \in D$ and points $z_1, \ldots, z_N \in D$. We call the interpolation data $D \rightarrow D, \lambda_j \mapsto z_j, j = 1, \ldots, N,$ extremally solvable if it is solvable; i.e., there is a map $h \in \mathcal{O}(D, D)$ such that $h(\lambda_j) = z_j, j = 1, \ldots, N,$ and there is no $f$ holomorphic on a neighborhood of $D$ with the image in $D$ such that $f(\lambda_j) = z_j, j = 1, \ldots, N.$

Note that the latter condition is equivalent to the fact that there is no $h \in \mathcal{O}(D, D)$ such that $h(\lambda_j) = z_j, j = 1, \ldots, N,$ and $h(D)$ is relatively compact in $D$.

This leads us to the following definition (see [17]). Let $f : D \rightarrow D$ be an analytic disc. Let $\lambda_1, \ldots, \lambda_N \in D$ be pairwise distinct points. We say that $f$ is a weak $N$-extremal with respect to $\lambda_1, \ldots, \lambda_N$ if the problem

$$D \rightarrow D, \lambda_j \mapsto f(\lambda_j), j = 1, \ldots, N,$$

is extremally solvable.

Naturally, we shall say that $f$ is a weak $N$-extremal if it is a weak extremal with respect to some $N$ pairwise distinct points in the unit disc.

The idea of the above definition has roots in [1], where authors introduced the notion of $N$-extremal maps, demanding that the above problem is extremal for all choices of pairwise distinct points $\lambda_1, \ldots, \lambda_N$. Our definition of extremals is weaker; however, for many domains classes of $N$-extremals and weak $N$-extremals coincide (see [17]). This is the case for among others homogenous (i.e., with transitive group of holomorphic automorphisms) and balanced domains. In particular, both definitions are equivalent for the Euclidean ball. Similar maps were also investigated by Edigarian [11].

The dual problem to the one presented above (we call it the $N$-Pick problem for $D$) is to interpolate the following problem:

$$D \rightarrow D, z_j \mapsto \lambda_j, j = 1, \ldots, N,$$

i.e., to find an $F \in \mathcal{O}(D, D)$ such that $\lambda_j = F(z_j), j = 1, \ldots, N$. The problem is extremal if there is no $G \in \mathcal{O}(D, D)$ with $G(z_j) = \lambda_j, j = 1, \ldots, N,$ and the image $G(D)$ lies relatively compactly in $D$.

The two problems present two different generalizations of the classical Nevanlinna-Pick problem in the unit disc which are mutually dual.

In the paper we show a very close relation between them for $D = \mathbb{B}_n$ and $N = 3$.

2.2. Case $N = 2$. Lempert theorem. Recall that in the case $N = 2$ the mutual relationship between the above two problems is well understood. In the case of the ball and the polydisc the description of extremal problems is obtained very easily. In a much more general case of bounded convex domains the same description of the extremality of the problems

$$D \rightarrow D, z_j \mapsto \lambda_j, j = 1, 2,$$
and
\[ D \to D, \quad \mu_j \mapsto z_j, \quad j = 1, 2, \]
is a consequence of the Lempert theorem (see \[ 19 \]). More precisely, for the fixed \( z_1, z_2 \in D \) the extremality of (1) and (2) implies the existence of the interpolating functions \( f \in \mathcal{O}(D, D) \) and \( F \in \mathcal{O}(D, \mathbb{D}) \) such that \( F \circ f \) is an automorphism of \( D \) (in the language we shall use, Blaschke products of degree 1). Moreover, for the given distinct points \( z_1, z_2 \in D \) the existence of the extremal interpolation function \( F \) and corresponding points \( \lambda_1, \lambda_2 \) in the problem (1) (respectively, the existence of the extremal interpolation function \( f \) and \( \mu_1, \mu_2 \) in the problem (2)) implies the existence of \( f \) and \( \lambda_1, \lambda_2 \) (respectively, \( F \) and \( \mu_1, \mu_2 \)) as above. One of our aims is to find an analogue to this description in the case of \( N = 3 \) and \( D \) being the unit ball \( \mathbb{B}_n \).

2.3. Complex \( N \)-geodesics. The above observations make us recall the following definition (see \[ 17 \]). An analytic disc \( f : \mathbb{D} \to D \) is called a complex \( N \)-\( \text{geodesic} \) if there is a holomorphic function \( F : D \to \mathbb{D} \) such that \( b := F \circ f \) is a non-constant Blaschke product of degree at most \( N - 1 \). The function \( F \) is called a \( \text{left inverse} \) to the complex \( N \)-\( \text{geodesic} \) \( f \).

Recall that if \( f : \mathbb{D} \to D \) is a complex \( N \)-\( \text{geodesic} \), \( F : D \to \mathbb{D} \) is its left inverse, and \( b := F \circ f \), then for any pairwise distinct \( \lambda_1, \ldots, \lambda_N \in \mathbb{D} \) the interpolation problems
\[ D \to \mathbb{D}, \quad f(\lambda_j) \mapsto b(\lambda_j), \quad j = 1, \ldots, N, \]
and
\[ \mathbb{D} \to D, \quad \lambda_j \mapsto f(\lambda_j), \quad j = 1, \ldots, N, \]
are extremal.

2.4. Solution of the extremal 3-point problem in the ball. In our paper we deal with \( D := \mathbb{D}_n \) and \( N = 3 \). The main result of the paper is the following.

Theorem 1. Let \( F \in \mathcal{O}(\mathbb{B}_n, \mathbb{D}) \) and let \( z_1, z_2, z_3 \in \mathbb{B}_n \) be pairwise different. A 3-point \( \text{Pick} \) problem in \( \mathbb{B}_n \),
\[ \mathbb{B}_n \to \mathbb{D}, \quad z_j \mapsto \lambda_j := F(z_j), \quad j = 1, 2, 3, \]
is extremal if and only if there is an \( f \in \mathcal{O}(\mathbb{D}, \mathbb{B}_n) \) such that either \( f \) passes through the points \( z_1, z_2, z_3 \) and \( F \circ f \) is a non-constant Blaschke product of degree at most 2 or \( f \) passes through at least two of the points \( z_1, z_2, z_3 \) and \( F \circ f \) is a Blaschke product of degree 1.

Actually, we prove much more than what is stated above. Before we may state the most general results we need to introduce some notion and recall known facts. However, at this place to show that the results we have are to a wide extent effective, we present a theorem describing a class of interpolating functions. This description follows directly from Theorems (3) and (5) which contain more detailed results.

Theorem 2. If the 3-point \( \text{Pick} \) interpolation problem
\[ \mathbb{B}_n \to \mathbb{D}, \quad z_j \mapsto \lambda_j, \quad j = 1, 2, 3, \]
is extremal, then, up to a composition with automorphisms of \( \mathbb{B}_n \) and \( \mathbb{D} \), it is interpolated by a function which belongs to one of the classes
\[ \mathcal{F}_D := \left\{ x = (x_1, \ldots, x_n) \mapsto \frac{2x_1(1 - \tau x_1) - \tau \omega x_2^2}{2(1 - \tau x_1) - \omega x_2^2} \mathcal{E}, \quad |\tau| = 1, |\omega| \leq 1 \right\} \]
and
\[ F_{ND} := \left\{ x = (x_1, \ldots, x_n) \mapsto \frac{x_1^2}{2 - a^2} + \frac{2\sqrt{1 - a^2}x_2}{2 - a^2} : a \in [0, 1) \right\}. \]

2.5. Geometry of the unit ball. To proceed with the presentation of main results let us recall some well-known facts on the unit ball (see e.g. \[14\] and \[22\]). First recall that the group of automorphisms of \( \mathbb{B}_n \) is generated by idempotent mappings \( \chi_w, \quad w \in \mathbb{B}_n \), and unitary mappings. For the fixed \( w \) the mapping \( \chi_w \) is the automorphism interchanging \( w \) and \( 0, \quad w \in \mathbb{B}_n \). In the special case of the unit disc \( (n = 1) \) we put \( m_a := \chi_a, \quad a \in \mathbb{D} \). Then \( m_a \) is the idempotent Möbius map. Recall that the automorphisms of the unit ball map the parts of complex lines lying in the ball onto the same type of sets. Moreover, any three points from the ball may be mapped by some automorphism into a given two-dimensional intersection of an affine subspace with the ball.

We also need to know the effective formula for the Carathéodory distance of the unit ball - the uniquely determined holomorphically invariant function (for the definition of the Carathéodory distance and its properties see e.g. \[14\]):
\[
c_s^\mu_n(w, z) = \sqrt{1 - \frac{(1 - ||w||^2)(1 - ||z||^2)}{|1 - \langle w, z \rangle|^2}}, \quad w, z \in \mathbb{B}_n,
\]
where \( \langle \cdot, \cdot \rangle \) denotes the standard inner product in \( \mathbb{C}^n \).

2.6. Reformulation of the extremal 3-point Pick problem in the ball. Thanks to the transitivity of the group of automorphisms of the ball, while considering the 3-point Pick problem in the ball we may, without loss of generality, restrict ourselves to the problem
\[
\mathbb{B}_n \to \mathbb{D}, \quad 0 \mapsto 0, \quad z \mapsto \sigma, \quad w \mapsto \tau,
\]
where \( z \neq w, \quad z \neq 0, \quad w \neq 0, \) and \( (\sigma, \tau) \neq (0, 0) \).

Let us come back to the formulation of our main problem. In order to do it we repeat reasoning from \[16\] which allows us to formulate the problems in a more handy way.

Let us denote \( \mathcal{D}_n := \{(z, w) \in \mathbb{B}_n \times \mathbb{B}_n : z \neq w, z \neq 0, w \neq 0\} \).

A standard Montel-type argument shows that for any \((z, w) \in \mathcal{D}_n\) and any \((\sigma, \tau) \in \mathbb{C}^2 \setminus \{(0, 0)\}\) there is exactly one \( t = t_{z, w, (\sigma, \tau)} > 0 \) such that the problem
\[
(4) \quad \mathbb{B}_n \to \mathbb{D}, \quad 0 \mapsto 0, \quad z \mapsto t\sigma, \quad w \mapsto t\tau
\]
is extremal. It is simple to see that the mapping
\[
\mathcal{D}_n \times (\mathbb{C}^2 \setminus \{(0, 0)\}) \ni (z, w, \sigma, \tau) \mapsto t_{z, w, (\sigma, \tau)} \in \mathbb{R}_{>0}
\]
is continuous. Moreover, for fixed nodes \( z, \quad w \) the mapping \([\sigma : \tau] \mapsto (t_{z, w, (\sigma, \tau)} \sigma, \quad t_{z, w, (\sigma, \tau)} \tau)\) gives a \( 1 - 1 \) correspondence between the projective plane \( \mathbb{P}^1 \) and the set of target points for which \([14]\) is extremally solvable modulo a unimodular constant. When we refer to the extremal 3-point Pick problem corresponding to the data \((z, w, [\sigma : \tau])\) we mean the problem
\[
\mathbb{B}_n \to \mathbb{D}, \quad 0 \mapsto 0, \quad z \mapsto t_{z, w, (\sigma, \tau)} \sigma, \quad w \mapsto t_{z, w, (\sigma, \tau)} \tau.
\]

In particular, the target points \( t_{z, w, (\sigma, \tau)} \sigma \) and \( t_{z, w, (\sigma, \tau)} \tau \) are determined up to a unimodular constant.
2.7. Degenerate and non-degenerate cases. An extremal 3-point Pick problem in $D$,
\[ D \rightarrow \mathbb{D}, \quad z_j \mapsto \lambda_j, \ j = 1, 2, 3, \]
is called non-degenerate if no 2-point subproblem is extremal.

We divide the set $D_n \times \mathbb{P}^1$ into three sets $A$, $B$ and $C$ with $A \cap B = \emptyset$, $A \cup B = D_n \times \mathbb{P}^1$, and $A$ open.

We say that an element $(z, w, [\sigma : \tau]) \in D_n \times \mathbb{P}^1$ belongs to the set $A$ (respectively, $B$) if and only if its corresponding extremal 3-point Pick problem is non-degenerate (respectively, degenerate). Moreover, we define $C$ to consist of points $(z, w, [\sigma : \tau])$ such that $0$, $z$ and $w$ lie in the range of a 2-extremal. In other words this means that points $0$, $z$, and $w$ are co-linear. It is clear that $C$ is a proper analytic set.

Our aim will be the effective description of $B$ from which we shall conclude that $A \setminus C$ is connected and thus so is $A$. We shall see that for any extremal function $F \in \mathcal{O}(\mathbb{B}_n, \mathbb{D})$ corresponding to the extremal 3-point Pick problem $(w, z, [\sigma : \tau])$ there will be an $f : \mathbb{D} \rightarrow \mathbb{B}_n$ such that $F$ is a left inverse to $f$ (and thus $f$ is a complex 3-geodesic). In the case $(z, w, [\sigma : \tau]) \in B$ we may effectively pick the extremal function $F$ from a given class of functions (to be defined later), whereas the existence of extremal functions $f$ corresponding to the extremals $F$ for points from $A$ will follow from some topological argument (relying on connectivity of $A \setminus C$).

This idea is the same as in the recent paper [16] concerning the same problem but in the polydisc. In the latter case we shall be able to find the class of extremal functions, too.

2.8. Description of the degenerate case. The description of the set $B$ is given below. Note that the degeneracy of the extremal 3-point Pick problem
\[ \mathbb{B}_n \rightarrow \mathbb{D}, \quad w \mapsto F(w), \ z \mapsto F(z), \ u \mapsto F(u), \]
where $F \in \mathcal{O}(\mathbb{B}_n, \mathbb{D})$, means that for two distinct points, say $w, z$, we have $c_0^w(w, z) = c_0^z(F(w), F(z))$. Composing nodes with automorphisms of $\mathbb{B}_n$ we lose no generality assuming that $w = 0$, $F(0) = 0$, and $F(z_1, 0') = z_1$ for some, and consequently, applying the Schwarz lemma, for any $z_1 \in \mathbb{D} \setminus \{0\}$. Therefore, the description of $B$ reduces to the description of the possible values of $F(u)$ for fixed $u \in \mathbb{B}_n$ where $F \in \mathcal{O}(\mathbb{B}_n, \mathbb{D})$ satisfies $F(z_1, 0) = z_1, z_1 \in \mathbb{D}$.

In other words the problem of description of $B$ reduces to the description, for the fixed $w \in \mathbb{B}_n$, of the set
\[ \mathcal{B}(w) := \{ F(w) : F \in \mathcal{O}(\mathbb{B}_n, \mathbb{D}), F(z_1, 0') = z_1, z_1 \in \mathbb{D} \}. \]

One more reduction is possible: due to the form of the group of automorphisms of $\mathbb{B}_n$, the point $w$ may be assumed to be from $\mathbb{B}_2 \times \{0\}$. It is therefore sufficient to discuss the case $n = 2$.

Summarizing, the set $\mathcal{B}(w)$ comprises the possible values $\sigma$ of the degenerate extremal 3-point Pick problem in $\mathbb{B}_2$,
\[ \mathbb{B}_2 \rightarrow \mathbb{D}, \quad (0, 0) \mapsto 0, \ (z_1, 0) \mapsto z_1, \ w \mapsto \sigma, \]
for some (any) $z_1 \in \mathbb{D}_\mathbb{z}$.

Note that having given a function $G \in \mathcal{O}(\mathbb{B}_2, \mathbb{D})$ such that $G(z_1, 0') = z_1, z_1 \in \mathbb{D}$, any function of the form
\[ z \mapsto \tau G(\tau z_1, \omega z_2), \]
where $|\tau| = 1, |\omega| \leq 1$ maps $\mathbb{B}_2$ to $\mathbb{D}$ and points $(z_1, 0)$ to $z_1$.

Define
\[ F_{1,1}(z) := \frac{2z_1(1 - z_1) - z_2^2}{2(1 - z_1) - z_2^2}, \quad z \in \mathbb{B}_2. \]

Note that \( F_{1,1} \in \mathcal{O}(\mathbb{B}_2, \mathbb{D}) \) - it is a straightforward consequence of elementary transformations. It is also worth mentioning that we deduced the formula for the function \( F_{1,1} \) as a function playing a special role in describing the set \( B(w) \) using the fact that it lies in the closure of the set of non-degenerate points.

For \( |\tau| = 1, |\omega| \leq 1 \) define
\[
F_{\tau,\omega}(z) := \tau F_{1,1}(\tau z_1, \omega z_2) = \frac{2\tau z_1(1 - \tau z_1) - \tau^2 \omega^2 z_2^2}{2(1 - \tau z_1) - \omega^2 z_2^2}. 
\]

Then \( F_{\tau,\omega} \in \mathcal{O}(\mathbb{B}_2, \mathbb{D}) \) and \( F_{\tau,\omega}(z_1, 0) = z_1. \) The functions just introduced show non-uniqueness of left inverses to complex geodesics in the ball, and their form is much simpler than the one studied in [18].

The fact that \( B(w) \) has non-empty interior is one of the main results of [7]. Our next theorem precisely describes this set.

**Theorem 3.** Let \( w \in \mathbb{B}_2 \). Then
\[
B(w) = m_{w_1} \left( B \left( 0, \frac{w_2}{\sqrt{1 - |w_1|^2}} \right) \right) = m_{w_1} \left( \bigtriangleup \left( 0, \frac{|w_2|^2}{2 - 2|w_1|^2 - |w_2|^2} \right) \right),
\]

where \( \bigtriangleup(\lambda_0, r) := \{ \lambda \in \mathbb{C} : |\lambda - \lambda_0| \leq r \} \), \( \lambda_0 \in \mathbb{C}, r \geq 0. \) In particular, the set \( B(w) \) is a closed Euclidean disc.

Moreover, the extremal 3-point Pick interpolating functions in the degenerate case may be chosen from a nice class of functions. More precisely,
\[ B(w) = \{ F_{\tau,\omega}(w) : |\tau| = 1, |\omega| \leq 1 \}. \]

In Theorem 3 not only do we have the effective description of the set \( B(w) \) (and thus \( B \)) but also we find the class of extremal mappings which deliver all the possible values in the degenerate case.

In any case it will follow from the above theorem that the set \( A \) is connected (see Lemma 13). This fact will be crucial in the proof of the next theorem.

### 2.9. Description of the non-degenerate case

Let \( U_n(\mathbb{C}) \) denote the \( n^2 \)-dimensional Lie group of unitary matrices.

Below we present a construction that allows us to derive Theorem 1 in the non-degenerate case. As already mentioned, it is sufficient to express it for \( n = 2 \).

Let us consider a mapping \( \Phi \) defined on the set
\[
\Omega := \{(x, y, a, U, c) \in \mathbb{D}_* \times \mathbb{D}_* \times (0, 1) \times U_2(\mathbb{C}) \times (-1, 1) : x \neq y\}
\]
by the formula
\[
\Phi(x, y, a, U, c) := (\varphi_{a, U, c}(x), \varphi_{a, U, c}(y), [xm_{\gamma}(x) : ym_{\gamma}(y)]),
\]
where \( \gamma = \frac{2c}{1 + |c|^2} \), \( \varphi_{a, U, c}(\lambda) := \chi_w(U(am_{\gamma}(\lambda), (1 - a^2)^{1/2} m_{\gamma}(\lambda))), \lambda \in \mathbb{D}. \) Recall that \( m_c \) is the idempotent Möbius map switching 0 and \( c \), and \( \chi_w \), where \( w = U((1 - a^2)^{1/2} c, ac^2) \), is an idempotent automorphism of the Euclidean unit ball switching 0 and \( w \).

Let us formulate a result which is contained in the proof of Theorem 5.8 in [24].
Proposition 4 (See [21]). Let $a, U, c, \gamma$ be as above. Then there is a holomorphic mapping $F : \mathbb{B}_2 \to \mathbb{D}$ such that

$$F(\varphi_{a,U,c}(\lambda)) = \lambda m_\gamma(\lambda), \lambda \in \mathbb{D}.$$ 

In particular, $\varphi_{a,U,c}$ is a 3-complex geodesic (that is not a 2-extremal), and $F$ is its left inverse.

The above proposition implies that the image of $\Phi$ lies in the set $\mathcal{A} \setminus \mathcal{C}$ (see Lemma 8 for details). Our aim is to show more. Namely, we have

Theorem 5. With the notation as above, $\Phi(\Omega) = \mathcal{A} \setminus \mathcal{C}$.

In other words, there is a correspondence (in fact 2 : 1) between the three extremals and the non-degenerate 3-point Pick problem in the ball. Moreover, as we shall see the solution of the non-degenerate extremal 3-point Pick problem in the ball may also be taken from a relatively simple class of functions.

An analogous result holds in the polydisc (see [16]). However, there are some differences between the case of the ball and that of the polydisc. First note that unlike in the case of the polydisc the case of the unit ball may be easily reduced (due to the form of holomorphic automorphisms) to the two-dimensional case. For instance the proof in the polydisc was different in dimension 2, 3, and at least 4. Second, the situation in the ball differs from that in the polydisc since the degenerate case in the ball is a big one.

3. Degenerate case - proof of Theorem 3

At first we clarify the situation when the degeneracy is ‘strong’. Roughly speaking the result below says that if two of three 2-point subproblems corresponding to $(z, w, \xi)$ are extremal, then $(z, w, \xi)$ lies in $\mathcal{C}$. More precisely:

Lemma 6. Assume that two of three 2-point subproblems of the 3-problem Pick problem

$$\mathbb{B}_n \to \mathbb{D}, \quad z_i \mapsto \sigma_i, \quad i = 1, 2, 3,$$

are extremal. Then $z_1, z_2, z_3 \in \mathbb{B}_n$ lie on a common complex affine line.

Proof. Let $F$ be a function interpolating the above 3-point Pick problem. Since automorphisms of the Euclidean ball map complex affine lines into complex affine lines we may assume that $z_3 = 0$, $z_1 = (z'_1, 0)$, and the subproblems comprising $z_1, z_3$, and $z_2, z_3$ are extremal. We may also assume that $\sigma_3 = 0$ and $\sigma_1 = z_1$. Suppose the claim does not hold, so $z_2 = \lambda_0 v$ for some $\lambda_0 \in \mathbb{D} \setminus \{0\}$, where $||v|| = 1$ and $|v_1| < 1$. Then it is clear that $F(\lambda, 0) = \lambda$ and $F(\lambda v) = e^{i\theta} \lambda$ for some $\theta \in \mathbb{R}$ and all $\lambda \in \mathbb{D}$.

Consequently,

$$(c^*_{\mathbb{B}_n}((z'_1, 0), \lambda v))^2 \geq c^*_{\mathbb{D}}(F(z'_1, 0), F(\lambda v))^2 = (c^*_{\mathbb{D}}(z'_1, e^{i\theta} \lambda))^2, \lambda \in \mathbb{D},$$

which is equivalent to

$$|1 - e^{i\theta} \lambda z_1|^2 \leq |1 - \lambda v_1 z_1|^2, \lambda \in \mathbb{D}.$$ 

Substituting $\lambda$ in the unit circle such that $\text{Re}(e^{i\theta} \lambda z_1) = -|z_1|$ we get a contradiction.

Now we proceed to the proof of Theorem 3
Proof of Theorem 3. We shall make use of the invariance of the sets $B(w)$ under automorphisms, so at first we study the case of $w \in \{0\} \times \mathbb{D}$. To do this define
\[
u(z_2) := \sup\{|F(0, z_2)| : F \in \mathcal{O}(\mathbb{B}_2, \mathbb{D}), F(z_1, 0) = z_1\}, \quad z_2 \in \mathbb{D}.
\]
It is simple to see that $u(z_2) = u(|z_2|)$.

We claim that
\[
u(z_2) \leq \frac{|z_2|^2}{2 - |z_2|^2}, \quad z_2 \in \mathbb{D}. \tag{8}
\]

Fix $1 > z_2 \geq 0$. Take $F \in \mathcal{O}(\mathbb{B}_2, \mathbb{D})$ such that $F(z_1, 0) = z_1$, $z_1 \in \mathbb{D}$. Without loss of generality assume that $x := F(0, z_2) \geq 0$. The holomorphic contractibility of the Carathéodory distance gives
\[
(c^*_B(z_1, 0), (0, z_2)))^2 \geq (c^*_D(F(z_1, 0), F(0, z_2)))^2 = c^*_D(z_1, x)^2
\]
for any $z_1 \in \mathbb{D}$. The last inequality may be written in the form
\[
1 - (1 - |z_1|^2)(1 - |z_2|^2) \geq \frac{z_1 - x}{1 - x z_1}^2, \quad z_1 \in \mathbb{D}.
\]

Consider only $z_1 \in (-1, 1)$. Then the last inequality is equivalent to
\[
x^2(1 - z_1^2)(1 + z_1^2 - z_2^2) - 2 x z_1(1 - z_1^2)(1 - z_2^2) - z_2^2(1 - z_1^2) \leq 0, \quad z_1 \in (-1, 1).
\]
Consequently,
\[
x^2(1 + z_1^2 - z_1^2 z_2^2) - 2 x z_1(1 - z_2^2) - z_2^2 \leq 0, \quad z_1 \in (-1, 1).
\]

Passing $z_1 \to -1$ we get that
\[
x^2(2 - z_2^2) + 2 x(1 - z_2^2) - z_2^2 \leq 0.
\]

The last is equivalent to the inequalities $-1 \leq x \leq \frac{z_2^2}{2 - z_2^2}$, which finishes the claim.

The inequality (3) implies that for any $w_2 \in \mathbb{D}$ we get the inclusion $B(0, w_2) \subset \{\sigma : |\sigma| \leq \frac{|w_2|^2}{2 - |w_2|^2}\}$. To see the opposite inclusion fix $w_2 \in \mathbb{D}$. Then manipulating with $|\tau| = 1$, $|\omega| \leq 1$ we easily find that for any $|\sigma| \leq \frac{|w_2|^2}{2 - |w_2|^2}$ there is a function $F := F_{\tau, \omega}$ such that $F(0, w_2) = \sigma$. In fact, $F_{\tau, \omega}(0, w_2) = \frac{\omega \tau w_2}{2 - \omega^2 w_2}$, and now observe that the continuous function
\[
\mathbb{D} \ni \omega \mapsto \frac{\omega^2 w_2^2}{2 - \omega^2 w_2^2} \tag{9}
\]
attains the values 0 (for $\omega = 0$) and some point of the absolute value equal to $\frac{|w_2|^2}{2 - |w_2|^2}$ (for $|\omega| = 1$ such that $\omega^2 w_2^2 = |w_2|^2$), and thus the connectedness of the image of the function implies for any $|\sigma| \leq \frac{|w_2|^2}{2 - |w_2|^2}$ the existence of $\tau$ and $\omega$ as desired. This gives the desired description of $B(0, w_2)$.

Recall that $\chi_{(w_1, 0)}(z) = \left( m_{w_1}(z_1), \frac{\sqrt{1 - |w_1|^2}}{1 - w_1 \bar{z}_1} z_2 \right), \quad z \in \mathbb{B}_2$.

Note that for any function $F \in \mathcal{O}(\mathbb{B}_2, \mathbb{D})$ such that $F(z_1, 0) = z_1$, $z_1 \in \mathbb{D}$, the function $G := m_{w_1} \circ F \circ \chi_{(w_1, 0)} \in \mathcal{O}(\mathbb{B}_2, \mathbb{D})$ and it satisfies the equality $G(z_1, 0) = z_1$, $z_1 \in \mathbb{D}$, too.
Since \( \chi(w_1,0)(w) = \left(0, \frac{w_2}{\sqrt{1-|w_1|^2}}\right) \) this implies that
\[
B(w) = m_{w_1} \left( B \left(0, \frac{w_2}{\sqrt{1-|w_1|^2}}\right) \right),
\]
which gives the desired description. In particular, for any \( w \in B_2 \) the set \( B(w) \) is the closed Euclidean disc lying in \( \mathbb{D} \). More precisely it is a closed disc with respect to the Poincaré distance (the function \( c_{D}^{\circ} \)) centered at \( w_1 \).

The above procedure also allows us to construct functions that give all the values \( F(w) \) from the set \( A(w) \). It follows from the above reasoning (and the result for \( w \in \{0\} \times \mathbb{D} \)) that these extremal values will be attained by functions from the class
\[
\{ m_{w_1} \circ F_{\tau,\omega} \circ \Psi_{(w_1,0)} : |\tau| = 1, |\omega| \leq 1 \}.
\]

But this class (formally depending on \( w \)) is the same for all \( w \), and consequently it coincides with that for \( (0,w_2) \) (some or any). To see this, it is sufficient to make elementary calculations to get that
\[
m_{w_1} \circ F_{\tau,\omega} \circ \Psi_{(w_1,0)}(z) = \frac{2 \left(1 - z_1 \frac{\overline{\tau - w_1}}{1 - \tau w_1}\right) z_1 + \omega^2 \frac{\bar{\tau} - w_1}{1 - \tau w_1} z_2^2}{2 \left(1 - z_1 \frac{\overline{\tau - w_1}}{1 - \tau w_1}\right) + \omega^2 \frac{\bar{\tau} - w_1}{1 - \tau w_1} z_2^2}.
\]
It is easy to observe that the last form is the function \( F_{\tilde{\tau},\tilde{\omega}} \), where \( \tilde{\tau} = \frac{\overline{\tau - w_1}}{1 - \tau w_1} \), \( \tilde{\omega}^2 = -\omega^2 \frac{\bar{\tau} - w_1}{1 - \tau w_1} \).

One may conclude more from the proof of Theorem 3. Note that in contrast with the situation in the polydisc in the case of the ball the set of degenerate extremal 3-point Pick problems is a ‘big’ one in the sense that the set \( B \) has non-empty interior. Moreover, as formulated in Theorem 3 the class of functions which gives all the possible values in this case is, up to automorphisms of the ball, recovered from a nice class of functions:
\[
\mathcal{F}_D = \{ F_{\tau,\omega} : |\tau| = 1, |\omega| \leq 1 \},
\]
where \( F_{\tau,\omega} \) is given by (6). It is interesting to note that in order to parametrize the boundary \( \partial B \) the corresponding class of functions may be chosen from the above one with the additional assumption that \( |\omega| = 1 \).

4. Non-degenerate case - proof of Theorem 3

4.1. 3-complex geodesics. It was proven in [24, Theorem 5.8] that any 3-extremal in the unit ball is a complex 3-geodesic. We recall the reasoning that led to this result.

Let \( f : D \to B_2 \) be a 3-extremal in the unit ball which is not a 2-extremal. Recall that then \( f \) is, up to a composition with an automorphism of \( B_n \), of the form
\[
\lambda \mapsto (a\lambda, \sqrt{1 - a^2 \lambda} m_\alpha(\lambda)),
\]
where \( a \in [0,1) \) and \( \alpha \in \mathbb{D} \) (see [17, Section 3]).

It was also proved in [17] that any such \( f \) with \( \alpha = 0 \) admits a left inverse of the form
\[
F(z) = \frac{z_1^2}{2 - a^2} + \frac{2\sqrt{1 - a^2} z_2}{2 - a^2},
\]
thus showing that such an \( f \) is a complex 3-geodesic.
Later, Warszawski in [24, Theorem 5.8] showed additionally that any 3-extremal \( f \) that is not a 2-extremal is actually equivalent with a 3-complex geodesic of the form
\[
\lambda \mapsto (am_\epsilon(\lambda), \sqrt{1 - a^2m_\epsilon^2(\lambda)}), \quad a \in [0, 1).
\]
A more detailed result on 3-geodesy of 3-extremals (not being 2-extremals) proven in [24] is presented in Proposition 4.

Remark that the above facts show that one may choose a relatively small class (modulo automorphisms of the unit ball) of left inverses that would be good for all 3-extremals. This class of functions equals (up to automorphisms)
\[
\mathcal{F}_{ND} = \left\{ \frac{z_1^2}{2 - a^2} + \frac{2\sqrt{1 - a^2z_2}}{2 - a^2} : a \in [0, 1) \right\}.
\]

These observations will be crucial in our subsequent considerations.

### 4.2. Left inverses.

As we have already mentioned the function \( F \) given by the formula \( F(z) = \alpha z_1^2 + \beta z_2 \) with \( \alpha = \frac{1}{2 - a^2}, \beta = \frac{2\sqrt{1 - a^2}}{2 - a^2} \) is a left inverse to \( \lambda \mapsto (a\lambda, b\lambda^2) \), where \( a, b \geq 0, a^2 + b^2 = 1 \). Elementary calculations also show that \( |F| \) attains its maximum on the topological boundary of \( \partial B_2 \) along the algebraic set \( \{z \in \partial B_2 : bz_1 = a^2z_2\} \).

This brings us to the following general situation: let \( D \) be a smooth domain in \( \mathbb{C}^n \) and let \( F \in \mathcal{O}(\overline{D}) \) be such that \( F(D) \subset \mathbb{D} \). Assume that there exists \( g \in \mathcal{O}(\overline{D}) \) such that \( \{z \in \partial D : |F(z)| = 1\} = \{z \in \partial D : g(z) = 0\} \cap \partial D \). Some methods coming from analytic geometry will allow us to show that there is \( \alpha \in \mathbb{N} \) such that
\[
F_K(z) := \frac{F(z)}{\sqrt{1 - Kg^\alpha(z)}} \in \mathbb{D}, \quad z \in D,
\]
whenever \( K > 0 \) is small enough.

Actually, let \( Z := \{|F| = 1\} \cap \partial D \). Lojasiewicz inequality (see e.g. [20]) gives
\[
C \, \text{dist}(z, Z)^\alpha \leq 1 - |F(z)|^2
\]
for \( z \in \partial D \). On the other hand, since \( Z \) is the zero set of \( g \) on \( \partial D \), for any \( x \in Z \) we get that \( |g(z)| = |g(z) - g(x)| \leq C'|z - x| \), so the following trivial inequality holds:
\[
|g(z)| \leq C' \, \text{dist}(z, Z).
\]

Now (12) and (13) together give
\[
K|g(z)|^\alpha + |F(z)|^2 < 1, \quad z \in \partial D,
\]
where \( K \) is small enough. The maximum principle finishes the proof of our claim.

Below we shall provide the reader with an elementary proof of the above fact for \( D \) being the unit ball and \( F \) given as above by the formula \( F(z) = \alpha z_1^2 + \beta z_2 \) and the function \( g \) given by the formula \( g(z) = bz_1 - a^2z_2 \). Beyond being elementary it has other advantages as it gives explicit formulas for \( \alpha \) and \( K \) satisfying the claim.

Let us fix the situation that we study. Let
\[
a \in (0, 1), \quad b := \sqrt{1 - a^2}, \quad F(z) := \frac{1}{2 - a^2}(z_1^2 + 2bz_2).
\]

As already mentioned \( F \) maps \( B_2 \) into \( \mathbb{D} \) and
\[
F(a\lambda, b\lambda^2) = \lambda^2, \quad \lambda \in \mathbb{D}.
\]
Lemma 7. With the notation as above for any $0 \leq \varepsilon < 1$ the function
\[
F_{\varepsilon}(z) := \frac{F(z)}{\sqrt{1 - \frac{\varepsilon^2}{(2-a^2)^2} (bz_1^2 - a^2z_2)^2}}
\]
maps $\mathbb{B}^2$ into $\mathbb{D}$.

Proof. To show the above property it is sufficient to show that
\[
|z_1^2 + 2bz_2|^2 + \varepsilon^2|a^2z_2 - bz_1^2|^2 < (2-a^2)^2
\]
on $\mathbb{B}^2$.

For $\varepsilon > 0$ such that $2b \geq \varepsilon^2a^2b$ it is sufficient to show that
\[
f(x) \leq f(b) = (2-a^2)^2, \quad x \in [0,1],
\]
where $f(x) := (1-x^2 + 2bx)^2 + \varepsilon^2(a^2x - b(1-x^2))^2$.

Since $f$ is a polynomial of degree 4 with the positive leading coefficient, $f(0) = 1 + \varepsilon^2b^2$, $f(1) = 4b^2 + \varepsilon^2(1-b^2)^2$, $f(b) = (1+b^2)^2$, $f'(b) = 0$, $f''(b) = -4(2-a^2) + 2\varepsilon^2(2-a^2)^2$ we easily conclude the desired inequality for $\varepsilon$ such that $f''(b) < 0$, and this is the case for $0 < \varepsilon < 1$. □

In the sequel we shall need the following observation:

Lemma 8. Let us keep the notation as in Subsection 2.9 Let $x, y \in \mathbb{D} \setminus \{0\}$ be such that $x \neq y$. Then the problem
\[
\mathbb{B}_2 \to \mathbb{D}, \quad 0 \mapsto 0, \quad \varphi(x) \mapsto x m_\gamma(x), \quad \varphi(y) \mapsto y m_\gamma(y),
\]
where $\varphi = \varphi_{a,u,c,\varepsilon}$ is extremal, non-degenerate, and omits $\mathcal{C}$. In other words $\Phi(x, y, a, U, c) \in \mathcal{A} \setminus \mathcal{C}$ for any $(x, y, a, U, c) \in \Omega$.

Proof. Extremality is clear, as Blaschke products are 3-extremals in $\mathbb{D}$.

We shall show that the subproblem
\[
\mathbb{B}_2 \to \mathbb{D}, \quad 0 \mapsto 0, \quad \varphi(x) \mapsto x m_\gamma(x)
\]
is not extremal. The proof for two other 2-point subproblems is based on the same idea.

Note that extremality of the above 2-point subproblem is equivalent to the equality (use [14] and the definition of the $\varphi$).
\[
c_{\varepsilon_{\mathbb{B}_2}}((ac^2, (1-a^2)^{1/2}, am_\varepsilon(x), (1-a^2)^{1/2} m_\varepsilon(x))) = c_{\mathbb{D}}((c^2, m_\varepsilon^2(x))).
\]

Put $y = m_\varepsilon(x)$ and $b = (1-a^2)^{1/2}$. The last equality means that there is a geodesic $\psi$ in $\mathbb{B}_2$ such that $\psi(c^2) = (ac^2, bc)$ and $\psi(y^2) = (ay^2, by)$. Let $F_{\varepsilon}$ be functions constructed in Lemma 7 such that $F_{\varepsilon}(b\lambda, a\lambda^2) = \lambda^2$, $0 \leq \varepsilon < 1$. Note that $F_{\varepsilon} \circ \psi$ is the identity for any $0 \leq \varepsilon < 1$, so due to the form of $F_{\varepsilon}$ we get the equality $av_2^2 \equiv b^2\psi_2$ on $\mathbb{D}$. This means that the image of $\psi$ lies in the variety $\{(\lambda, a/b^2\lambda^2), \lambda \in \mathbb{D}\}$. Since geodesics lie on affine lines we find that $a = 0$. But then $c_{\varepsilon_{\mathbb{B}_2}}((0, c), (0, y)) = c_{\mathbb{D}}((c^2, y^2))$, a contradiction.

Finally, we shall show that $0, \varphi(x)$, and $\varphi(y)$ are not co-linear. Since automorphisms of $\mathbb{B}_2$ map affine lines into affine lines the assertion is equivalent to an obvious fact that $(am_\varepsilon(0), bm_\varepsilon^2(0))$, $(am_\varepsilon(x), bm_\varepsilon^2(x))$, and $(am_\varepsilon(y), bm_\varepsilon^2(y))$ do not lie on an affine line. □
4.3. Openness of the range of $\Phi$.

**Lemma 9.** The continuous mapping $\Phi : \Omega \to A \setminus C$ is two-to-one. Moreover, $\Phi(x, y, a, U, c) = \Phi(-x, -y, a, U, -c)$.

In particular, $\Phi$ is locally injective on any domain composed of points such that $x \neq y$.

**Proof.** It follows from the definition that the equality $\Phi(x, y, a, U, c) = \Phi(-x, -y, a, U, -c)$ holds for any $(x, y, a, U, c) \in \Omega$. What remains to be proven is to show that if $\Phi(x_1, y_1, a_1, U_1, c_1) = \Phi(x_2, y_2, a_2, U_2, c_2)$, then either $(x_1, y_1, a_1, U_1, c_1) = (x_2, y_2, a_2, U_2, c_2)$ or $(x_2, y_2, a_2, U_2, c_2) = (-x_1, -y_1, a_1, U_1, -c_1)$.

Assume that $\Phi(x_1, y_1, a_1, U_1, c_1) = \Phi(x_2, y_2, a_2, U_2, c_2)$. To simplify the notation let us denote $\varphi_i = \varphi_{a_i, U_i, c_i}$ and $\gamma_i = \frac{2c_i}{1+|c_i|^2}$, $b_i = (1 - a_i^2)^{1/2}$, $w_i = U_i(a_i, c_i, b_i c_i^2)$, $\chi_i = \chi_{w_i}$, $i = 1, 2$. Notice that if the problem

$$\mathbb{B}_2 \rightarrow \mathbb{D}, \quad 0 \mapsto 0, \varphi_1(x_1) \mapsto x_1 m_{\gamma_1}(x_1), \varphi_1(y_1) \mapsto y_1 m_{\gamma_1}(y_1)$$

is interpolated by a function $F$, then the problem

$$\mathbb{B}_2 \rightarrow \mathbb{D}, \quad 0 \mapsto 0, \varphi_2(x_2) \mapsto x_2 m_{\gamma_2}(x_2), \varphi_2(y_2) \mapsto y_2 m_{\gamma_2}(y_2)$$

is interpolated by a function $\omega F$ for some unimodular $\omega$. Applying this observation to $F := m_{c_1} \circ F_\varepsilon \circ U_1^{-1} \circ \chi_1$, where $F_\varepsilon$ is a left inverse to $\lambda \mapsto (a_1 \lambda, (1 - a_1^2)^{1/2} \lambda^2)$ constructed in Lemma 7, $0 \leq \varepsilon < 1$, we get that there is some $\omega \in \partial \mathbb{D}$ such that

$$F_\varepsilon \circ U_1^{-1} \circ \chi_1 \circ \varphi_2(\lambda) = m_{c_1}(\omega \lambda m_{\gamma_2}(\lambda)), \quad \lambda \in \mathbb{D},$$

and any $\varepsilon < \sqrt{2}$.

**Claim 10.** Let $\psi \in \mathcal{O}(\mathbb{D}, \mathbb{B}_2)$. Assume that there is a Blaschke product of degree 2 such that

$$F_\varepsilon \circ \psi \equiv B$$

for any $0 \leq \varepsilon < 1$. Then $B \equiv \eta m^2$ for some Möbius map $m$ and unimodular constant $\eta$. Moreover, $\psi_2 \equiv b_1 m^2$ and $\psi_1^2 \equiv a_1^2 m^2$.

**Proof of the claim.** Since the equality $F_\varepsilon \circ \psi(\lambda) = B(\lambda)$ for $\lambda \in \mathbb{D}$ holds for all $\varepsilon$ small enough we get from the form of $F_\varepsilon$ that $b_1 \psi_1^2(\lambda) = a_1^2 \psi_2(\lambda)$ for $\lambda \in \mathbb{D}$. Direct computation gives equalities

$$B(\lambda) = F_\varepsilon(\psi(\lambda)) = F(\psi(\lambda)) = \psi_1^2(\lambda)/a_1^2, \quad \lambda \in \mathbb{D},$$

and the claim follows. \hfill $\square$

We come back to the proof of the lemma. Making use of the claim we see that

$$m_{c_1}(\omega \lambda m_{\gamma_2}(\lambda)) = \eta m^2_2(\lambda), \quad \lambda \in \mathbb{D},$$

for some idempotent Möbius map $m_\alpha$ and unimodular constant $\eta$. Differentiating \[16\] at the point $\alpha$ we find that $\gamma_2 = \frac{2\alpha}{1+|\alpha|^2}$; in particular, $\alpha \in \mathbb{R}$. Putting $\lambda = 0$ to \[16\] one gets $c_1^2 = \eta a_1^2$ and, therefore, $\eta = 1$ and $c_1^2 = a_1^2$. Consequently, $\gamma_2 = \pm \frac{2c_1}{1+|c_1|^2}$, which means that $c_2 = \pm c_1$. Putting $\lambda = 1$ to \[16\] one gets $\omega = 1$.

Replacing, if necessary, $(x_2, y_2, c_2)$ with $(-x_2, -y_2, -c_2)$ we may assume that $c_2 = c_1$. What we have to do now is show that $x_1 = x_2$, $y_1 = y_2$, $U_1 = U_2$, and $a_1 = a_2$.

Note that Claim \[10\] implies that

$$U_1^{-1} \circ \chi_1 \circ \varphi_2(\lambda) = J \circ U_1^{-1} \circ \chi_1 \circ \varphi_1(\lambda), \quad \lambda \in \mathbb{D},$$
where $J$ is either the identity matrix or $J = \text{diag}(-1,1)$. Substituting $\lambda = 0$ in the above equality we infer that $J$ fixes $(a_1 c_1, b_1 c_1^2)$, whence one deduces that $J$ is the identity. Consequently, $\varphi_2 \equiv \varphi_1$ so

$$\chi_2 \circ U_2(a_2 \lambda, b_2 \lambda^2) = \chi_1 \circ U_1(a_1 \lambda, b_1 \lambda^2), \quad \lambda \in \mathbb{D}.$$ 

Thus $\chi_2(0) = \chi_1(0)$, so $\chi_2 \equiv \chi_1$. Since $U_1$ and $U_2$ are isometries, the above relations imply that $||(a_1, b_1 \lambda)|| = ||(a_2, b_2 \lambda)||$ for any $\lambda \in \mathbb{D}$. Remembering that $a_i, b_i$ are positive, we simply deduce that $a_1 = a_2$, so $U_1 = U_2$ trivially. Finally, the equalities $x_1 = x_2$ and $y_1 = y_2$ follow immediately from the relations $\varphi_1(x_1) = \varphi_2(x_2)$ and $\varphi_1(y_1) = \varphi_2(y_2)$.

\[\square\]

4.4. Closedness of the range of $\Phi$.

Lemma 11. The range $\Phi(\Omega)$ is closed in $A \setminus C$.

Proof. We are using the notation as in Proposition 4. Let a sequence $((x_n, y_n, a_n, U_n, c_n))$ in $\Omega$, convergent to $(x_0, y_0, a_0, U_0, c_0)$ in $\Omega$, be such that the sequence $(\Phi(x_n, y_n, a_n, U_n, c_n)) =: (\Phi_n(x_n, y_n, \xi_n))$ is convergent to $(0, w_0, \xi_0) \in A \setminus C$. Put $\sigma_n := x_n m_{\gamma_n}(x_n)$ and $\tau_n := y_n m_{\gamma_n}(y_n)$. Assume additionally that sequences $(\sigma_n)$ and $(\tau_n)$ are convergent to $\sigma_0$ and $\tau_0$. We easily get that $\sigma_0, \tau_0 \in \mathbb{D}$. Additionally, it follows from the continuity argument that the problem

$$\mathbb{B}_2 \to \mathbb{D}, \quad 0 \mapsto 0, \quad z_0 \mapsto \sigma_0, \quad w_0 \mapsto \tau_0$$

is extremal.

And once more since the sequence $(\Phi(x_n, y_n, a_n, U_n, c_n))$ converges to an element from $A \setminus C$ we get that $a_0 \in (0,1)$.

Note that if we show that $c_0 \in (-1,1)$, then we are done.

Therefore, we may assume that $c_0$ converges to 1 (the case $c_0 = -1$ follows from the fact that $\Phi$ is even with respect to the variables $x, y, c$). In such a case the sequence $(\gamma_n)$ tends to $\gamma_0 = 1$. We shall consider three cases.

The first one is when $x_0 = y_0 = 1$. Then

$$c_{\mathbb{D}}^*(\sigma_0, \tau_0) = \lim c_{\mathbb{D}}^*(m_{\gamma_n}(x_n), m_{\gamma_n}(y_n))$$

$$= \lim c_{\mathbb{D}}^*(x_n, y_n) \geq \lim c_{\mathbb{B}_2}^*(z_n, w_n) = c_{\mathbb{B}_2}^*(z_0, w_0).$$

On the other hand we have the trivial inequality $c_{\mathbb{D}}^*(\sigma_0, \tau_0) \leq c_{\mathbb{B}_2}^*(z_0, w_0)$. Both these relations imply that the 2-point problem

$$\mathbb{B}_2 \to \mathbb{D}, \quad z_0 \mapsto \sigma_0, \quad w_0 \mapsto \tau_0$$

is extremal, so $(z_0, w_0, \xi_0) \in \mathcal{B}$, a contradiction.

Now suppose that $x_0 \in \mathbb{D}$. Then $\sigma_0 = x_0$, which implies that the 2-point problem $0 \mapsto 0, \quad z_0 \mapsto \sigma_0$ is extremal, a contradiction also. If $y_0 \in \mathbb{D}$ we proceed similarly.

We are left with the case when $x_0, y_0 \in \partial \mathbb{D}$ and either $x_0 \neq 1$ or $y_0 \neq 1$. But this means that either $\tau_0$ or $\sigma_0$ does not lie in the unit disc, which leads to a contradiction also. \[\square\]
4.5. Connectedness of non-degenerate set.

Lemma 12. Suppose that $z, w \in B_2$ do not lie on a line passing through 0. Then the set of points $\xi = [\sigma : \tau]$ such that $(z, w, \xi) \in A$ is connected.

Proof. To prove the assertion we shall show that points $\xi$ for which $(z, w, \xi) \in B$ form a union of three disjoint simply-connected and closed sets.

Two of them are closed discs consisting of points $\xi = [\sigma : \tau]$ such that one of the following 2-point interpolation subproblems

$$0 \mapsto 0, \quad z \mapsto t_{z,w,(\sigma,\tau)} \sigma \quad \text{or} \quad 0 \mapsto 0, \quad w \mapsto t_{z,w,(\sigma,\tau)} \tau$$

is extremal (use Theorem 3).

To get the assertion it thus suffices to show that the set of $\xi$ such that

$$z \mapsto t_{z,w,(\sigma,\tau)} \sigma, \quad w \mapsto t_{z,w,(\sigma,\tau)} \tau$$

is extremal is simply-connected. The reason for this is that all the sets constructed here are disjoint, according to Lemma 6.

Let us compose nodes and points with proper automorphisms so that we are in a position that allows us to apply Theorem 3 again. Then one can see that we aim to describe $[\sigma : \tau]$ such that $m_\sigma(\tau) = ||x|| = x_1 > 0$ (and thus $x_2 = 0$) and $c_\sigma^*(\tau, z_1) \leq \frac{|z_2|^2}{2-2|x_1|^2-|z_2|^2} =: r$, where $x = (x_1, x_2) = (x_1, 0) = U(\chi_z(w))$ with suitably chosen unitary matrix $U$.

But then $\tau = \frac{\sigma - x_1}{1-x_1 \sigma}$. What we need is to show that the set

$$\left\{ \frac{\tau}{\sigma} = \frac{\sigma - x_1}{\sigma - x_1 \sigma} : \sigma \in \mathbb{D}, \ c_\sigma^*(\sigma, z_1) \leq r \right\} \subset \hat{\mathbb{C}}$$

is simply-connected (if $\sigma = 0$ the fraction with $0$ in the denominator is understood to be $\infty$).

We shall prove it. Since

$$\frac{\sigma - x_1}{\sigma - x_1 \sigma} = 1 - x_1 \frac{1 - |\sigma|^2}{\sigma - x_1 |\sigma|^2}$$

we easily reformulate the problem.

Consider the function

$$\psi : \mathbb{D} \ni \sigma \mapsto \frac{\sigma - x_1 |\sigma|^2}{1 - |\sigma|^2} \in \mathbb{C}.$$ 

Since any closed Poincaré disc in $\mathbb{D}$ is the Euclidean disc, to finish the proof of the lemma it is sufficient to show that for any closed disc $K \subset \mathbb{D}$ the set $\psi(K)$ is simply-connected.

To prove it note that the (real) Jacobian of $\psi$ equals

$$\frac{1 + |\sigma|^2 - 2 \text{Re}(x_1 \sigma)}{(1 - |\sigma|^2)^3} > 0, \ \sigma \in \mathbb{D}.$$ 

Consequently $\psi$ is a local diffeomorphism. Note also that $\psi$ is proper onto its image (equal to $\mathbb{C}$). Consequently, $\psi$ is a finite topological covering, which easily implies the desired conclusion. \hspace{1cm} $\Box$

Lemma 13. The set of non-degenerate points $(z, w, \xi)$ is connected.
Proof. Note that the set $C_1$ of $(z, w)$ lying on the same complex line is analytic, so removing it does not affect the connectedness.

Thus the result is a consequence of the trivial fact that the natural projection

$$A \setminus C \ni (z, w, \xi) \mapsto (z, w) \in D_n \setminus C_1$$

is open and Lemma 12, which says that fibers of the above projection are connected. □

Proof of Theorem 5. It follows from Lemmas 9 and 11 that the range of the mapping $\Phi$ is open and closed in $A \setminus C$, which is connected, according to Lemma 13 □

5. PROOF OF THEOREM 11

Proof of Theorem 11. The existence of $f$ as in the theorem easily implies the extremality of the 3-point Pick problem. So assume the problem formulated in the theorem is extremal.

First recall that if the problem

$$B_n \rightarrow \mathbb{D}, \quad z \mapsto \mu_j := F(z_j), \quad j = 1, 2, 3,$$

is degenerate, then by Lempert’s theorem there is a complex geodesic $f$ in $B_n$ passing through (at least) two of the nodes such that $F \circ f$ is a Möbius map (see Section 2.2). Thus the theorem in this case is clear.

Let us assume that (17) is non-degenerate. As mentioned in Section 2.6 one may assume that $z_3 = 0$ and $\lambda_3 = 0$.

The assertion is clear if $(z_1, z_2, [\mu_1 : \mu_2])$ lies in the range of $\Phi$, which is equal to $A \setminus C$ (see Theorem 5).

Therefore, it suffices to show that the theorem holds if $(z_1, z_2, [\mu_1 : \mu_2])$ is in $C$. Recall that this means that $z_1$ and $z_2$ lie on a complex line. Let $z_j = \lambda_j v$, $j = 1, 2$, for some $v \in \mathbb{C}^n$, $\|v\| = 1$. Let $U$ be a unitary matrix such that $U(1, 0, \ldots, 0) = v$.

Define $B(\lambda) := F(U(\lambda, 0, \ldots, 0))$ and $f(\lambda) := U(\lambda, 0, \ldots, 0)$, $\lambda \in \mathbb{D}$. $f$ interpolates the extremal 3-point problem

$$\mathbb{D} \rightarrow B_n, \quad 0 \mapsto 0, \quad \lambda_j \mapsto \lambda_j v, \quad j = 1, 2.$$

Then the problem

$$\mathbb{D} \rightarrow \mathbb{D}, \quad 0 \mapsto 0 = B(0), \quad \lambda_j \mapsto B(\lambda_j), \quad j = 1, 2,$$

is extremal. Actually, otherwise there would be a $g \in \mathcal{O}(\mathbb{D}, \mathbb{D})$ with $g(0) = 0$, $g(\lambda_j) = B(\lambda_j) = F(z_j)$, $j = 1, 2$, and $g(\mathbb{D})$ lying relatively compactly in $\mathbb{D}$. Then define $G$ with $G(z) := g(U^{-1}(z)))$, $z \in B_n$, where $\pi$ is the projection onto the first variable. Then $G \in \mathcal{O}(B_n, \mathbb{D}), G(0) = 0, G(z_j) = F(z_j), j = 1, 2$, and $G(B_n)$ lies relatively compactly in $\mathbb{D}$, which contradicts the extremality of $F$. Therefore, $B$ is a Blaschke product of degree at most 2, which completes the proof. □

6. RELATIONS WITH THE GREEN FUNCTION WITH TWO POLES

For a domain $D \subset \mathbb{C}_n, p, q, z \in D, p \neq q$, define $l_D(p; q; z)$ as the minimum of three values:

$$\inf\{|\lambda| : \exists f \in \mathcal{O}(\mathbb{D}, D) : f(0) = z, f(\lambda) = p, f(\sigma) = q\},$$

$$\inf\{|\lambda| : \exists f \in \mathcal{O}(\mathbb{D}, D) : f(0) = z, f(\lambda) = p\},$$

$$\inf\{|\lambda| : \exists f \in \mathcal{O}(\mathbb{D}, D) : f(0) = z, f(\lambda) = q\}.$$
We also define
\[ c_D(p; q; z) := \sup \{|F(z)| : F \in \mathcal{O}(D, \mathbb{D}), F(p) = F(q) = 0\}. \]

Then \( c_D \leq l_D \). Let \( D \) be additionally bounded and \( z \neq p, q \). Then we may find an \( F \in \mathcal{O}(D, \mathbb{D}) \) with \( F(p) = F(q) = 0 \) and \( F(z) = c_D(p; q; z) =: \tau \). Note that the 3-point Pick problem
\[ D \to \mathbb{D}, \quad p \mapsto 0, \quad q \mapsto 0, \quad z \mapsto \tau \]
is then extremal and \( F \) interpolates it. It is then simple to see that the existence of a holomorphic \( f : \mathbb{D} \to D \) passing through three points \( p, q, \) and \( z \) such that \( F \circ f \) is a non-Blaschke product of degree at most 2 or the existence of a holomorphic \( f : \mathbb{D} \to D \) passing through at least two of the points \( p, q, z \) such that \( F \circ f \) is a non-constant Blaschke product of degree 1 (note that in the latter case \( f \) must necessarily pass through \( z \)!) implies the equality
\[ c_D(p; q; z) = l_D(p; q; z). \]
The above equality implies that the Green function with logarithmic poles at \( p \) and \( q \) at \( z \) coincides with both \( \log c_D(p; q; z) = \log l_D(p; q; z) \), and thus this shows that in such a case the conjecture of Coman with two poles does hold (see [10]).

In view of Theorem 1 the equality (18) holds for \( D = \mathbb{B}_n \), and thus this gives another proof showing that the conjecture of Coman holds for the unit ball with two logarithmic poles (see [10], [12]).
