The kinetics of the cathode process on tungsten in KF-AlF₃-Al₂O₃ melts and suspensions was studied by means of voltammetry and galvanostatic polarization. The effects of the temperature, [KF]/[AlF₃] ratio, Al₂O₃ content on the kinetic parameters of electrowinning of aluminum from the KF-AlF₃-Al₂O₃ melts and suspensions were determined. Introducing Al₂O₃ slurry into the suspension and increasing its proportion made the diffusion of the electroactive ions to the cathode more difficult. The parameters for the suspension electrolysis were chosen on the basis of electrochemical measurements. The possibility of aluminum production during the electrolysis of KF-AlF₃-Al₂O₃ suspension with 45 wt% Al₂O₃ in the solid phase was demonstrated.

The Al₂O₃ content in the electrolytes of industrial electrolytic melts and suspensions is a very promising technique.1–5 New electrode and construction materials can be used to permit a lowering of the temperature during the electrolysis. 

Preparation of electrolytes.—

KF-AlF₃ melts. Data on Al₂O₃ solubility in the investigated melts and suspensions at the temperatures under study are presented in Table I. Suspensions having a 30% and 45% excess of alumina were chosen for experimental purposes based on the sedimentation effect: the study of cathode processes having a lower solid phase content is complicated by rapid sedimentation.

Experimental

Preparation of electrolytes.—The melts and suspensions were prepared from individual KF, AlF₃ (Chemically Pure Grade, OJSC “Vekton”, Russia) and Al₂O₃ (UC “RUSAL”) compounds. The mixture of KF and AlF₃ having the required [KF]/[AlF₃] ratio was placed into the corundum crucible of the electrochemical cell and heated up to the working temperature by means of a resistance furnace. Then the prepared KF-AlF₃ mixtures were purified by means of potentiostatic electrolysis to remove residuals (electropositive in relation to the aluminum impurities; 2 hours at a 0.2 V vs. the potential of aluminum electrode12,13). Aluminium oxide was added into the purified KF-AlF₃ melts. Data on Al₂O₃ solubility in the investigated melts and suspensions at the temperatures under study are presented in Table I. Suspensions having a 30% and 45% excess of alumina were chosen for experimental purposes based on the sedimentation effect: the study of cathode processes having a lower solid phase content is complicated by rapid sedimentation.

The melts and suspensions were

Electrochemical measurements.—Electrochemical measurements were carried out at temperatures of 670–800 °C in a three-electrode corundum cell under air. Tungsten (W) rods (1 mm, immersion 10 mm) served as a working electrode. A graphite cylinder was used to form a counter electrode (working surface 12 cm²). The potential of the working electrode was measured relative to the potential of the aluminum reference electrode.24

The results of the study supplement scarce data on the kinetics of aluminum electrowinning from KF-AlF₃-Al₂O₃ melts and suspensions.21–23

Results and Discussion

Voltammetry.—The typical cyclic voltammograms (CVs) obtained on W electrode in 1.5KF-AlF₃-Al₂O₃(sat) melt are shown on Fig. 1. The temperatures were 715, 750, and 800 °C and the potential sweep rate (v) varies from 0.01 to 0.5 V s⁻¹. CVs contains one cathode peak (AI) of the aluminum reduction at 715 (current density) is likely to be solely due to the Al₂O₃ dissolution. 25

The latter form of alumina (γ-Al₂O₃) dissolves in a cryolite-alumina melt much more slowly than the former. Thus, an excess of Al₂O₃ promotes the formation of crusts at the bottom of the electrolyzer. The lowering of the temperature reduces the rate of α-Al₂O₃ formation and allows melts saturated with Al₂O₃ to be used as well as the suspensions.1,2 In this case, the rate of the electrochemical process (current density) is likely to be solely due to the Al₂O₃ dissolution.

In terms of the anode process, the using KF-AlF₃-Al₂O₃ suspension for the electrolytic production of aluminium at lower temperature can reduce the chemical oxidation of carbon anodes and provide faster removal of anode gases from the denser electrolyte.

The present work is devoted to a determination of the kinetic features of the cathode process on tungsten in KF-AlF₃-Al₂O₃ melts and suspensions. The KF-AlF₃-based molten systems were chosen due to the higher solubility of Al₂O₃ at the investigated temperatures.

Table I. Al₂O₃ solubility in the melts under study.

| Melt/suspension composition, wt % | [KF]/[AlF₃], Mol mol⁻¹ | Electrolyte 670 | 715 | 750 | 800 |
|----------------------------------|------------------------|----------------|-----|-----|-----|
| 47.4KF-52.6AlF₃                  | 1.3                    | 1.3KF-AlF₃-Al₂O₃(sat) | 4.20 | 4.85 | 5.50 |
| 50.9KF-49.1AlF₃                  | 1.5                    | 1.5KF-AlF₃-Al₂O₃(sat) | 5.70 | 6.85 | 8.35 |

of the potassium reduction (K) at more negatively values than −0.5 V (vs. Al). There is one peak (Al') of aluminum oxidation on the anode sides of CVs at 0.1...0.2 V (vs. Al). The complicated form of anode peak can indicate different forms of reduced aluminum. The rise of the working temperature from 715 to 800°C multiplies the values of the anode and cathode currents on CVs by 1.5–2.0. At the same time the peak currents on CVs at 750 and 800°C are closely matched. We assume that this is due to the reducing diffusion resistances with increasing temperature. Analogous CVs were obtained in the 1.3KF-AlF₃-Al₂O₃(sat) melt (Fig. 2).

The effects of the 30 and 45 wt% solid Al₂O₃ additions to the KF-AlF₃-Al₂O₃(sat) melts on CVs at different temperatures (for \( \nu = 0.1 \) V s⁻¹) are shown in Figs. 3 and 4. As is seen, the addition of the solid Al₂O₃ and further increases of its content in the KF-AlF₃-Al₂O₃(sat) suspensions decrease the peak current densities \( j_{pc} \) of the aluminum electrowinning (especially at the higher temperatures of 750 and 800°C).
The values of potentials ($E_{pc}$) and cathode peak current densities ($j_{pc}$) at different temperatures ($T$) and potential sweep rates ($v$) for the aluminum electrowinning from the KF-AlF$_3$-Al$_2$O$_3$ melts and suspensions are listed in Tables II and III. Relationships $j_{pc}(v^{1/2})$ for all conditions are generally linear (Fig. 5). This means that the process under study is primarily limited by the diffusion. Some shifting of $E_{pc}$ with the $v$ rising indicates the quasi-reversibility of the process (Tables II and III). Conversely, the increases in the solid Al$_2$O$_3$ content in the KF-AlF$_3$-Al$_2$O$_3$ (sat) suspensions made the diffusion more difficult. Numerically, the described effects can be analyzed from the diffusion coefficients (Table IV) of the electroactive ions ($D$) to the W electrode, estimated for the diffusion-controlled process by the Randles-Sevcik equation:\textsuperscript{25,26}

$$j_{pc} = -0.4463(zF)^{3/2}C(vD/RT)^{1/2}$$

where $R$ – gas constant, $R = 8.314$ J mol$^{-1}$ K$^{-1}$; $T$ – temperature, K; $z$ – number of electrons, $z = 3$; $F$ – Faraday constant, $F = 96487$ C mol$^{-1}$; $j_{pc}$ – cathode peak current density, A cm$^{-2}$; $C$ – concentration of the electroactive ions, mol cm$^{-3}$; $v$ – potential sweep rate, V s$^{-1}$; $D$ – diffusion coefficient of the electroactive ions, cm$^2$ s$^{-1}$.

Concentration $C$ was calculated using the data both on the Al$_2$O$_3$ solubility in the KF-AlF$_3$-Al$_2$O$_3$ melts\textsuperscript{18–20} and the melt densities\textsuperscript{27,28} by equation $C = \rho \varphi/M_\text{Al}_2\text{O}_3$ (\(\rho\) – melt density, g cm$^{-3}$, \(\varphi\) – solubility of Al$_2$O$_3$, wt\%, \(M_\text{Al}_2\text{O}_3\) – molar mass of Al$_2$O$_3$, $M_\text{Al}_2\text{O}_3 = 102$ g mol$^{-1}$). The $C$ values for the KF-AlF$_3$-Al$_2$O$_3$ (sat) melts were taken for the $D$ estimation in suspensions.

The $D$ values in the KF-AlF$_3$-Al$_2$O$_3$ melts were from 0.5 to $3.4 \times 10^{-5}$ cm$^2$ s$^{-1}$ depending on the temperature and [KF]/[AlF$_3$] ratio (Table IV). These are close to the $D$ values obtained for graphite and platinum electrodes in previous works.\textsuperscript{21,22} The addition of the solid Al$_2$O$_3$ and increases in its content in the KF-AlF$_3$-Al$_2$O$_3$ (sat) suspensions lead to decreasing $D$ values at the same temperature.

---

**Figure 3.** CVs obtained on W electrode in 1.5KF-AlF$_3$-Al$_2$O$_3$ melt (1) and suspensions with 30 (2) and 45 (3) wt\% of the solid Al$_2$O$_3$ at different temperatures. Potential sweep rate $-0.1$ V s$^{-1}$.

**Figure 4.** CVs obtained on W electrode in 1.3KF-AlF$_3$-Al$_2$O$_3$ melt (1) and suspensions with 30 (2) and 45 (3) wt\% of the solid Al$_2$O$_3$ at different temperatures. Potential sweep rate $-0.1$ V s$^{-1}$.
increases in the current density at −0.7–0.8 V (vs. Al) on GPCs for the 1.5KF-AlF₃-Al₂O₃(sat) melt indicates potassium electroreduction. The temperature rises and lowering of [KF]/[AlF₃] ratios leads to increases in the \( i_d \) values.

The effects of the 30 and 45 wt% solid Al₂O₃ additions to the KF-AlF₃-Al₂O₃(sat) melts on GPCs signals at the different temperatures are shown on Figs. 7 and 8. As well as for CVs, the addition of the solid Al₂O₃ and further increases in its content in the KF-AlF₃-Al₂O₃(sat) suspensions decrease the \( j_d \) of the aluminum electrowinning for all temperatures. Decreases in the values of \( j_{pc} \), \( D \), and \( j_d \) (from CVs and GPCs) can be caused both by increasing the diffusion layer thickness (b) and decreasing the convection flows with the addition of the solid Al₂O₃ phase.

**Electrolysis test.**—The parameters of the suspension electrolysis were determined on the basis of stationary measurements. The explanation of this choice is given below.

1. The suspension with the [KF]/[AlF₃] of 1.3 mol mol⁻¹ was chosen due to the lower liquidus temperature\(^5\) and larger limit current densities at the same other conditions. Hence, it is possible to carry out high-dissolution-rate electrolysis of Al₂O₃ at lower temperatures.\(^5\) Further lowering of the [KF]/[AlF₃] ratio can additionally decrease the possible operating temperature. However, this seems not to be appropriate due to the significant lowering of the Al₂O₃ solubility and its dissolution rate\(^5,20\) with temperature decreases. In addition, increases in the melt viscosity and the phase overvoltage should be taken into account.

2. The optimal temperature of the 1.3KF-AlF₃-Al₂O₃(sat) suspension electrolysis is 700–720°C. This temperature supports the liquid state of aluminum in the electrolytic cell and the lower electrolyte overheating.

3. The optimal content of solid Al₂O₃ in suspension is 45 wt%. Limit current densities for 1.3KF-AlF₃-Al₂O₃ suspensions with both 30% and 45 wt% Al₂O₃ are practically equal. At the same time, the sedimentation ability of the latter is lower. This is conducive for better separation of the anolyte and catholyte.

Electrolysis of the 1.3KF-AlF₃-Al₂O₃ suspension with 45 wt% Al₂O₃ in solid phase was carried out using the parameters:

- current \(- 20 \text{ A}\);
- cathode current density \(- 0.2 \text{ A cm}^{-2}\);
- anode current density \(- 0.4 \text{ A cm}^{-2}\);
- anode-cathode distance \(- 2 \text{ cm}\);
- voltage \(- 4.5-6.0 \text{ V}\);
- temperature \(- 715 \text{ °C}\).

Photographs of the working electrolyzer as well as photos of the electrodes and solidified suspension after the electrolysis are presented in Fig. 9. Considerable gas evolution was observed on the anodes (including lateral sides) during the electrolysis (Fig. 9a). Composition of the anode gas was not determined in present work, but we assume that the CO₂ was the main anode product at a relatively high anode current density (more than 0.05–0.10 A cm⁻²).\(^12,30,31\) Cathodic aluminum was formed near the W cathode in form of 2–8 mm droplets (Fig. 9b). The cathode was also well wetted by aluminum (Fig. 9b). Cathode current efficiency (applied quantity of electricity–48 A·h) was above than 50%. This value is comparable to the cathode current efficiencies obtained for other types of laboratory electrolyzers.\(^5,7,10\)

The results obtained indicate the possibility of the electrolytic production of aluminum during the electrolysis of the low-temperature KF-AlF₃-Al₂O₃ suspension with relatively high current efficiency. However, further study is needed, including research into the processes (particularly the kinetics of the anode process as well as the composition of anode gases) during electrolysis and optimization of the suspension composition and electrolysis parameters.

Conclusions

The effects of the temperature, [KF]/[AlF₃] ratio, Al₂O₃ content (melt, saturated with Al₂O₃; suspensions with 30 and 45 wt% Al₂O₃) on the kinetic parameters of the aluminum electrowinning from the KF-AlF₃-Al₂O₃ melts and suspensions were studied both under stationary and non-stationary conditions.

It was shown that the introduction of Al₂O₃ slurry and increases in its proportion impede the diffusion of the electroactive ions to the cathode. It was shown from both stationary and non-stationary measurements that the introduction of slurred Al₂O₃ into the suspension and increases in its proportion impede the diffusion of the electroactive ions to the cathode.

The parameters for the suspension electrolysis were chosen on the basis of electrochemical measurements. The possibility of producing aluminum through the electrolysis of a KF-AlF₃-Al₂O₃ suspension with 45 wt% Al₂O₃ in the solid phase was demonstrated.
