\textbf{Keywords:} Unramified cover • Quaternion algebra • Shimura variety • Arithmetic group

\section{1. Introduction}

Let \(C_1, C_2\) be smooth complex projective curves. Assume that one has a diagram

\[
\begin{array}{c}
C \\
\downarrow \quad f_2 \\
C_2
\end{array}
\begin{array}{c}
C \\
\downarrow \quad f_1 \\
C_1
\end{array}
\]

with \(f_1, f_2\) étale surjective morphisms. A \textit{co-fibered product} is the universal diagram of the form

\[
\begin{array}{c}
C \\
\downarrow \quad f_2 \\
C_2 \\
\downarrow \quad g_2 \\
C'
\end{array}
\begin{array}{c}
C \\
\downarrow \quad f_1 \\
C_1 \\
\downarrow \quad g_1 \\
C'
\end{array}
\]

with \(C'\) a curve, \(g_1, g_2\) surjective finite morphisms and

\[g_1f_1 = g_2f_2.\]

The starting point for this note was the following question of J. Kollár: are there obstructions to the existence of co-fibered products for unramified covers in the category of Riemann surfaces? In the language of function fields, the condition is equivalent to the triviality of the intersection of the function fields \(k(C_1) \cap k(C_2) \subset k(C)\).

More generally, let $X$ be an algebraic variety over an algebraically closed field $k$ of dimension $n$. Let $K = k(X)$ be its function field. Consider subfields $k(Y_1), k(Y_2) \subset k(X)$, with $\dim(Y_1) = \dim(Y_2) = \dim(X)$. We show that under mild conditions on $k$ and the varieties $Y_1, Y_2$, one has indeed

$$k(Y_1) \cap k(Y_2) = k.$$  

This can be achieved as soon as $k^*$ has an element of infinite order. We will also show that both field extensions $k(X)/k(Y_1)$ and $k(X)/k(Y_2)$ can be unramified, thus satisfying the condition that $f_1$ and $f_2$ above be étale. Using a theorem of Margulis we show that co-fibered products for unramified covers exist unless the curves in question are Shimura curves. Thus our construction provides all counterexamples. In case of curves over the complex numbers, we will give examples with small covering degrees, e.g., $\deg(g_1) = \deg(g_2) = 3$.

In positive characteristic, related questions on intersections of some specific function fields have been considered in [1–3, 5, 6]. A sample result from [1] is: If $k$ is perfect field of characteristic $p$ then

$$k(x^{p^n} + x^{p^n-1}) \cap k(x^n) \neq k$$

if and only if $\gcd(p, n) = 1$. A more precise description of $k(f) \cap k(g)$ is in [2]. However, the question remains whether co-fibered products exist for unramified covers of curves over $\mathbb{F}_p$.

2. Elementary examples

It is easy to construct examples of ramified covers: Let $K := k(\mathbb{P}^1)$ and assume that $k^*$ contains an element $a$ of infinite order. Let us take two involutions

$$\sigma : x \mapsto 1/x, \quad \text{and} \quad \sigma_0 : x \mapsto a/x.$$  

They generate a dihedral group $\mathfrak{D}_a$ with commutator

$$[\sigma, \sigma_0] : x \mapsto x/a^2$$

of infinite order. The fields of invariants $k(x)^{\sigma}$ and $k(x)^{\sigma_0}$ have index 2 in $k(x)$, but the intersection consists of elements which are invariant under $\mathfrak{D}_a$ and hence only of constants.

More generally, let $G \subseteq \text{PGL}_2(k)$ be an infinite subgroup generated by two elements of finite order. The subfields of invariants of $k(\mathbb{P}^1)$ have the required property. Note that such groups $G$ do not exist for $k$ an algebraic closure of a finite field. Indeed, any finite set of elements in $\text{PGL}_2(\mathbb{F}_q)$ is contained in a subgroup $\text{PGL}_2(\mathbb{F}_{p^r})$, for some $q = p^r$, so that this approach fails to produce nonintersecting subfields.

3. Shimura varieties

Natural examples of curve covers arise in the theory of arithmetic groups. Let $G$ be a semi-simple algebraic group defined over a number field $F$. Fix a model $\mathcal{G}$ of $G$ over the ring of integers $\mathcal{O}_F$. For every real embedding $i : F \to \mathbb{R}$ we have a complex symmetric space

$$\mathbb{D}_i := \mathcal{G}_i(\mathbb{R})/\mathcal{K}_i, \quad \mathbb{D} := \bigcap_i \mathbb{D}_i$$

where $\mathcal{K}_i$ is a maximal compact subgroup. We have a homomorphism

$$\phi : \mathcal{G}(\mathcal{O}_F) \to \bigcap_i \mathcal{G}_i(\mathbb{R}).$$

Let $\Gamma \subseteq \phi(\mathcal{G}(\mathcal{O}_F))$ be a subgroup of finite index and

$$X_F := \Gamma \backslash \mathbb{D}.$$
The quotient \( X \) is a complex algebraic variety defined over some finite extension of \( \mathbb{Q} \). For \( h \in \phi[G(F)] \) let \( \Gamma_h := h\Gamma h^{-1} \). Then \( \Lambda_h := \Gamma_h \cap \Gamma \) is a subgroup of finite index in \( \Gamma \) and \( \Gamma_h \). Thus there are surjective maps
\[
X := \mathbb{D}/\Lambda_h \xrightarrow{f_1} \mathbb{D}/\Gamma = X_T \\
\mathbb{D}/\Gamma_h = X_h
\]
Both maps are defined over some number field \( F' \). Thus we have two field embeddings
\[
f_1^*(F'(X_T)) \subset F'(X), \quad f_2^*(F'(X_{\Gamma_h})) \subset F'(X).
\]

Lemma 3.1.
If \( h \) is of infinite order in \( G(F) \) (modulo the center) then the intersection
\[
f_1^*(F'(X_T)) \cap f_2^*(F'(X_{\Gamma_h})) \subset K'(X)
\]
is a subfield of transcendence degree strictly smaller than \( \dim(X) \). If \( h \) and \( \Gamma \) generate a subgroup of \( G(F) \) which acts densely on \( \mathbb{D}/\Gamma \) then the intersection
\[
f_1^*(F'(X_T)) \cap f_2^*(F'(X_{\Gamma_h})) \subset F'(X)
\]
consists only of constants.

The same results hold for arbitrary extensions of \( F' \), in particular for complex numbers.

Proof. The field \( \mathbb{C}(X) \) consists of meromorphic functions on \( \mathbb{D} := \prod_i D_i \) which are invariant under the action of \( \Gamma_h \cap \Gamma \), and the subfields
\[
f_1^*(\mathbb{C}(X_T)), f_2^*(\mathbb{C}(X_{\Gamma_h}))
\]
of meromorphic functions invariant under \( \Gamma, \Gamma_h \) respectively. The intersection \( f_1^*(\mathbb{C}(X_T)) \cap f_2^*(\mathbb{C}(X_{\Gamma_h})) \) consists of functions invariant under both \( \Gamma, \Gamma_h \). If \( h \) has infinite order and if its power is not a central element in \( G(F) \) then \( \Gamma \cap \Gamma_h \) has infinite index in the group generated by \( \Gamma, \Gamma_h \). This is equivalent to \( \mathbb{C}(X_h) \) having an infinite degree over the intersection
\[
f_1^*(\mathbb{C}(X_T)) \cap f_2^*(\mathbb{C}(X_{\Gamma_h})).
\]
Since both fields are algebraic subfields the intersection is also algebraic, i.e., a finite extension of \( \mathbb{C}(y_1, \ldots, y_k) \) for some set \( y_1, \ldots, y_k \). This implies that \( k < \dim(X_h) \).

If \( \Gamma_h \cap \Gamma \) generate a subgroup which acts on \( \mathbb{D} \) with a dense orbit then there are no invariant meromorphic functions on \( \mathbb{D} \). Thus
\[
f_1^*(\mathbb{C}(X_T)) \cap f_2^*(\mathbb{C}(X_{\Gamma_h})) = \mathbb{C}.
\]

Since the maps \( f_i \) are defined over \( F' \) the same holds for arbitrary intermediate subfields \( \bar{F} \subset \mathbb{C}, F' \subset \bar{F} \). □

If the action of \( \Gamma \) on \( \mathbb{D} \) is cocompact then for a subgroup of finite index the stabilizers become trivial. Then both maps \( f_1, f_2 \) are finite unramified covers.

4. Curve covers

Consider \( \Gamma := \text{SL}_2(\mathbb{Z}) \) and \( \Gamma_h := h \text{SL}_2(\mathbb{Z})h^{-1} \), where \( h \in \text{SL}_2(\mathbb{Q}) \setminus \text{SL}_2(\mathbb{Z}) \). The intersection \( \Gamma \cap \Gamma_h \) has finite index in both groups. However, the action of the group generated by \( \Gamma \) and \( \Gamma_h \) on the upper-half plane \( \mathbb{H} \) is not discrete. In this case we have cusps, i.e., the corresponding maps are ramified. A similar argument applies to any arithmetic group acting on \( \mathbb{H} \).

Let \( D \) be a division algebra of dimension 4 over \( \mathbb{Q} \) which embeds into the \( 2 \times 2 \)-matrices \( M_2(\mathbb{R}) \). The splitting field of \( D \) is a real-quadratic field \( \mathbb{Q}(\sqrt{d}) \). Let \( \mathbb{C} \subset D \) be a subgroup of finite index in the group of integral quaternions with norm one which does not contain torsion elements. It acts discretely on \( \mathbb{H} \) with a compact quotient, the complex points of a projective algebraic curve \( C \). Let \( h \in D \) be an element with a nontrivial denominator and \( \Gamma_h := h\Gamma h^{-1} \). Write
\[
\Lambda_h := \Gamma_h \cap \Gamma.
\]
As in Section 3, we have covers

\[ X := \mathbb{D}/\mathbb{A}_h \rightarrow \mathbb{D}/\Gamma = X_\Gamma \]

\[ \mathbb{D}/\Gamma_h = X_{\Gamma_h} \]

On the other hand, the group generated by \( h \) and \( \Gamma \) acts nondiscretely on \( \mathbb{D} \). Thus there are no \( h, \Gamma \)-invariant elements in the function field \( \mathbb{C}(C') \) and hence no nontrivial common quotient. The groups \( \Gamma, \Gamma_h \) and \( \Lambda_h \) contain no elements of finite order. Hence they act freely on \( \mathbb{D} \) and the covers \( f_1 \) and \( f_2 \) are unramified.

We now present a series of examples with small covering degrees. Let \( D \) be a quaternion algebra over \( \mathbb{Q} \) with splitting field \( \mathbb{Q}(\sqrt{d}) \) for \( d > 0 \). Denote by \( \Gamma \subset D \) the subgroup of integer elements in \( D \) of norm 1. Assume that \( D \) has the following properties:

1. \( d \) is a square in \( \mathbb{Q}_2 \) and hence \( D \times \mathbb{Q}_2 = M_2(\mathbb{Q}_2) \).
2. \( \Gamma \) does not contain elements of finite order,
3. the completion of \( \Gamma \) surjects onto \( \text{SL}_2(\mathbb{Z}_2) \).

These conditions are easily satisfied. Note that \( D \) is dense in \( \text{GL}_2(\mathbb{Q}_2) \). Let \( h \in D \) be an element which modulo 4 is equal to

\[ \left( \begin{array}{cc} 1 & -1/2 \\ 0 & 1 \end{array} \right) \]  

and put \( \Gamma_h := h\Gamma h^{-1} \). The intersection

\[ \Lambda_h := \Gamma_h \cap \Gamma \]

contains a subgroup \( x = 1 \mod 2 \) and a subgroup modulo 4 generated by

\[ \left( \begin{array}{cc} 1 & 1 \\ 0 & 1 \end{array} \right) \]

This is a subgroup of index 3 in \( \Gamma \) and also in \( \Gamma_h \). The group \( \Lambda_h \) is the preimage of a congruence subgroup in \( \text{SL}_2(\mathbb{Z}_2) \).

Since \( \text{SL}_2(\mathbb{Z}/2) = \mathbb{S}_3 \) and the unipotent subgroup is \( \mathbb{Z}_2 \) we obtain that \( \Lambda_h \) has index 3.

The construction shows that it suffices to assume that \( \Gamma \) is a subgroup of finite index in the group of integral elements in \( D \) of norm 1, which has no torsion and whose completion surjects onto \( \text{SL}_2(\mathbb{Z}_2) \). For example, we can insist that \( g \in \Gamma \) satisfies \( g = 1 \mod p \), for some prime \( p \neq 2 \).

**Remark 4.1.**

We cannot achieve that both \( g_1, g_2 \) are of degree 2 and unramified. Indeed, in this example the corresponding extensions would be Galois, and the actions of both \( \mathbb{Z}/2 \) could be realized inside an action of a finite group \( H \) on \( C \). Thus \( k(C') \cap k(C'' \) contains \( k(C)^H \), a nontrivial field.

Let \( G \) be a semi-simple algebraic group over \( \mathbb{Q} \) and

\[ \text{Comm}_G(\Gamma) := \{ g \in G(\mathbb{R}) | [\Gamma : \{g\Gamma g^{-1} \cap \Gamma\}] < \infty \} \]

This is a well-defined subgroup of \( G(\mathbb{R}) \) containing \( \Gamma \).

Assume that \( \Gamma \subset \text{SL}_2(\mathbb{R}) \) is a discrete cocompact subgroup without torsion elements. Then \( X \) admits maps \( f_1, f_2 \) as above, if and only if \( \Gamma \) is an arithmetic subgroup of \( \text{SL}_2(\mathbb{R}) \). Note that

\[ [\text{Comm}_{\text{SL}_2(\mathbb{R})}(\Gamma) : \Gamma] < \infty \]

unless \( \Gamma \) is arithmetic. Indeed, we have the following
Theorem 4.1 ([4], Theorem (B), p. 298). Let $G$ be a semi-simple group over $\mathbb{Q}$ and $\Gamma \subset G(\mathbb{R})$ an irreducible lattice. Assume that $\Gamma$

(i) is of infinite index in $\text{Comm}_{\mathbb{C}}(\Gamma)$;

(ii) is finitely generated;

(iii) satisfies property $QD$.

Then $\Gamma$ is arithmetic.

In our applications, $\Gamma$ automatically satisfies properties (ii) and (iii) (see [4, Chapter IX] for definitions and results).
