Abstract. In the process of cyanidation of gold concentrate from a smelting company, the content of copper and zinc in the liquid gradually increased. In production, acidizing process is used to treat the lean solution from high copper concentrate, and mixed products containing copper, zinc and other metals are produced. In this paper, the pH value of zinc precipitation is 6.0 and the pH value of copper precipitation is 3.0 through theoretical calculation and experiment. The separation of copper and zinc in the lean solution is realized successfully. The zinc product with grade of 42.97% and the copper product with grade of 58.33% are produced.

1 Introduction

In the production process of a smelting company, the incoming gold concentrate enters the pre-leaching flotation process after grinding. In flotation, the gold concentrate is divided into high copper concentrate, high sulfur concentrate and low sulfur concentrate. After thickening and filtering, the three products respectively enter the corresponding cyanidation leaching system. The leaching solution is replaced by zinc powder, and the resulting lean solution returns to the cyanidation system. In the process of leaching, the copper and zinc in the lean liquor increase gradually. In the production, the lean liquor produced from high copper concentrate is treated by acidification to produce mixed products containing copper, zinc and other metals.

2 Brief introduction of the process

When copper and zinc are recovered from cyanide containing liquid respectively, two kinds of high-grade sulfide products can be produced. In the precipitation process, the main equilibrium reactions mainly include: the formation of HCN and the dissociation of H₂S, the sulfide precipitation of copper and zinc, the dissociation of cyanide containing ligands and the formation of precipitates [1-2].

During the reaction, the precipitation reaction of copper and zinc is as follows:

\[
\text{CN}^- + \text{H}^+ \rightarrow \text{HCN}
\]

\[
2\text{Cu(CN)}_2^+ + 8\text{H}^+ + \text{S}^2^- \rightarrow \text{Cu}_2\text{S}_4 + 8\text{HCN}
\]

\[
\text{Zn(CN)}_2^+ + \text{S}^2^- \rightarrow \text{ZnS} \downarrow + 4\text{CN}^-
\]

It can be seen from Formula (1)- (3) that in the reaction process, metal (complex) ions and sulfur ions can form metal sulfide precipitation under different conditions, and release hydrogen cyanide and free cyanide [3-4].

3 Theoretical calculation

3.1 Related parameters

Since there are many kinds of complex forms containing cyanide in copper, there is a complex equilibrium relationship between them. In this calculation process, it is considered that copper cyanide complex mainly exists in the form of \([\text{Cu(CN)}_4]^-\). Zinc sulfide exists in two forms, one of which is \(\alpha-\text{ZnS}\). The solubility product of \(\alpha-\text{ZnS}\) is easier to form in theory. The iron ions in the solution exist in the form of \(\text{Fe(CN)}_6^{3-}\).

The theoretical constant of 25°C is used in the calculation process, and the activity value is approximately replaced by the concentration value. The specific data are shown in Table 1.

| Dissociation Constant | Number | Solubility Product | Number |
|-----------------------|--------|--------------------|--------|
| HCN=H^+CN^-           | \(6.2 \times 10^{-10}\) | CuS                | \(2.5 \times 10^{44}\) |
| H₂S=H^+HS            | \(1.3 \times 10^{-7}\) | CuS               | \(6.3 \times 10^{38}\) |
| H₂S=H^+S²⁻          | \(7.1 \times 10^{15}\) | \(\alpha-\text{ZnS}\) | \(1.6 \times 10^{34}\) |
| Complex stability constant | Number | CuSCN              | \(4.8 \times 10^{13}\) |
| Cu(CN)_4^2⁻         | \(5.0 \times 10^{-28}\) | Cu₂[Fe(CN)_6]     | \(1.3 \times 10^{-18}\) |
| Zn(CN)_4^2⁻        | \(2.0 \times 10^{-11}\) | Zn₂[Fe(CN)_6]    | \(4.0 \times 10^{-18}\) |

3.2 Calculation of pH value in precipitation process

3.2.1 pH calculation of zinc precipitation

In the lean solution, Zn(CN)\(_2\) is the main zinc in the liquid. It can be seen from Table 1 that the complex stability constant is \(2.0 \times 10^{-17}\). When the concentration of zinc ion is 0.008 mol·L\(^{-1}\) in the solution, the concentration of cyanide ion is 1.51 \times 10^{-4} \text{ mol·L}^{-1}. The weak acid dissociation constant of hydrogen cyanide is 6.2 × 10^{-10}, When the pH value of the solution is less than 5.99, the dissociation reaction of Zn(CN)\(_2\) proceeds to the right, generating hydrogen cyanide gas and ZnS under the action of sulfur ion.

The reaction of zinc cyanogen complex in acid system is calculated as follows:
\[
\text{Zn(CN)}_4^{2-} \rightleftharpoons \text{Zn}^{2+} + 4\text{CN}^- \quad \text{K}_d = 2.0 \times 10^{-17} \quad (4)
\]

In the solution of 0.008 mol·L\(^{-1}\), it can be seen from the calculation that:
\[
\text{C(Zn}^{2+}) = 1.51 \times 10^{-4} \text{ mol·L}^{-1} \quad (5)
\]
\[
\text{C(CN}^-) = 6.03 \times 10^{-4} \text{ mol·L}^{-1} \quad (6)
\]
\[
\text{HCN} \rightleftharpoons \text{H}^+ + \text{CN}^- \quad \text{K}_a = 6.2 \times 10^{-10} \quad (7)
\]

When \(\text{C(H}^+) \cdot \text{C(CN}^-) = \text{K}_a\), HCN gas begins to overflow from the solution, the dissociation of copper cyanide complex proceeded to the right, and Cu\(^+\) gradually increased in the solution. From this we can calculate \(\text{C(H}^+) = 2.04 \times 10^{-4}\), the pH is 3.69.

4 Test

4.1 Test Sample

The sample used in this test is the lean solution produced by the leaching of high copper concentrate from a smelting company. The test results of main components in the sample are shown in Table 2.

| Table 2 Composition of test sample |
|-----------------------------------|
| Unit   | Cu  | Zn  | Pb  | SCN\(^-\) | SO\(_4^{2-}\) | CN\(^-\) |
|--------|-----|-----|-----|---------|-----------|---------|
| g/L    | 8.22| 0.55| 0.01| 26.98   | 40.42     | 3.90    |
| mol/L  | 0.13| 0.008| Trace| 0.47    | 0.42      | 0.15    |

It can be seen from table 2 that the content of copper and zinc is 8.22g/L and 0.55g/L respectively.

4.2 Test equipments and reagents

Na\(_2\)S·9H\(_2\)O, Three head reactor, Magnetic stirrer, Measuring cylinder, Concentrated sulfuric acid, Sodium hydroxide, Vacuum filter, Gas washing cylinder, The pH meter, Stopwatch, Constant pressure liquid funnel.

4.3 Test process

Zinc precipitation process: take a certain amount of lean liquid to be added to the reaction kettle placed on the magnetic stirrer, turn on the magnetic stirrer to make the rotor drive the lean liquid to rotate, insert the pH meter into the lean liquid, and slowly add sulfuric acid into the lean solution with a constant pressure separating funnel until the required pH value is reached, Na\(_2\)S·9H\(_2\)O is added, and the stopwatch is used to timing. After the reaction reaches the predetermined time, turn off the magnetic stirrer.

The liquid after reaction is separated by vacuum suction filter, and the liquid is retained for subsequent copper precipitation.

Copper precipitation process: add the filtered liquid in the zinc precipitation stage into the reactor placed on the magnetic stirrer, slowly add sulfuric acid into the lean solution with constant pressure separating funnel until the required pH value is reached, add Na\(_2\)S·9H\(_2\)O, use
stopwatch to timing, and turn off the magnetic stirrer after the reaction reaches the predetermined time. The liquid after reaction is separated by vacuum suction filter. The theoretical amount of sodium sulfide in the test is calculated according to formula 2) and formula 3).

4.4 Zinc precipitation test

4.4.1 The pH test

Under the condition that the amount of sodium sulfide is 1.2 times of the theoretical calculation amount and the reaction time is 5min, the test is carried out under different pH values. The test results are shown in Figure 1.

![Fig. 1 Changes of zinc precipitation rate under different pH values](image1)

It can be seen from Figure 1 that the change of pH value has a great influence on the precipitation rate of metal ions. When the pH value is less than 8.0, the precipitation rate of zinc increases rapidly. When the pH value is 6.0, the precipitation rate of zinc reaches 94.13%, and the precipitation rate of copper is low; When the pH value is less than 6.0, the copper in the liquid begins to precipitate. In order to ensure the separation effect of copper and zinc in lean solution, the pH value of zinc precipitation test was determined to be 6.0.

4.5 Copper precipitation test

4.5.1 The pH test

In the copper precipitation stage, sodium sulfide 1.2 times of the theoretical calculation amount was added, and the test was carried out under the condition of reaction time of 5min. The test results are shown in Fig.3.

![Fig. 2 Changes of copper precipitation rate under different pH values](image2)

It can be seen from Figure 3 that when the pH value is less than 4.0, the copper precipitation rate increases obviously. Considering that with the gradual decrease of pH value, a large amount of sulfate will be introduced into the pulp, it is determined that when the pH value is 3.0, the copper precipitation rate reaches 98.30%, and the zinc precipitation rate reaches 99.76%.

4.6 Product inspection

The three elements of copper, zinc and iron in the precipitation products were analyzed. The analysis results are shown in Table 3.

| Name            | Moisture content,% | Cu,%  | Zn,%  |
|-----------------|--------------------|-------|-------|
| Zinc product    | 60.85              | 2.04  | 42.97 |
| Copper product  | 58.63              | 58.33 | 1.58  |

According to table 3, the moisture content of zinc products and copper products is 60.85% and 58.63% respectively after filtration. The zinc grade of zinc products is 42.97%, and copper grade is 2.04%. The copper grade of copper products is 58.33%, and zinc grade is 1.58%.
Copper in zinc products is mainly due to the high local H+ concentration in the process of zinc precipitation and H2SO4, which cannot be dissolved back to CuS precipitation. The reason for the zinc content in copper products is that the laboratory cannot filter zinc precipitation thoroughly, and a small amount of zinc precipitates enter into the copper precipitation process.

5 Conclusion

(1) Through theoretical analysis, the pH value of zinc precipitation in lean solution of a smelting company is 5.99, and that of copper precipitation is 3.69.

(2) In the experiment, the pH value of zinc precipitation is 6.0, and the zinc precipitation rate is 94.13%; the pH value of copper precipitation is 3.0, and the copper precipitation rate is 98.30%. The zinc content in zinc products is 42.97%, and the copper content in copper products is 58.33%.

(3) This process realizes the separation of copper and zinc products in the lean solution, reduces the metal content in the lean solution, and increases the economic benefits of the enterprise.
