Additive Manufacturing and Injection Moulding of High-Performance IF-WS$_2$/PEEK Nanocomposites: A Comparative Study

Atefeh Golbang, Mozaffar Mokhtari, Eileen Harkin-Jones*, Edward Archer and Alistair Mcilhagger

Ulster University, Jordanstown, United Kingdom

In this study, PEEK nanocomposites with 0, 0.5, 1, and 2wt% IF-WS$_2$ were manufactured by injection moulding and Fused Deposition Modelling (FDM). To compare the impact of the two processing methods and the incorporated nanoparticles on the morphology, crystallization and final mechanical properties of the nanocomposites, SEM, DSC and tensile testing were performed. In general, a good distribution of nanoparticles was observed in PEEK, although larger agglomerates were visible at 2 wt% IF-WS$_2$. The crystallization degree of PEEK increased with increasing loading of IF-WS$_2$ nanoparticles up to 1wt% and then declined at 2 wt%, due to lower level of particle dispersion in this sample. The 3D printed samples showed slightly higher crystallinity at each IF-WS$_2$ loading in relation to the injection moulded samples and extruded filaments, because of multiple reheating effect from subsequent layer deposition during FDM, causing recrystallization. In general, incorporation of IF-WS$_2$ nanoparticles increased the mechanical properties of pure PEEK in both 3D printed and injection moulded samples. However, this increment was more noticeable in the 3D-printed nanocomposite samples, resulting in smaller gap between the mechanical properties of the 3D-printed samples and the injection moulded counterparts, in respect to pure PEEK, particularly at 1 wt% IF-WS$_2$. This effect is ascribed to the increased inter-layer bonding of PEEK in the presence of IF-WS$_2$ nanoparticles in FDM. In general, the lower mechanical properties of the 3D printed samples compared with the injection moulded ones are ascribed to poor interlayer bonding between the deposited layers and the presence of voids. However, addition of just 1 wt% of IF-WS$_2$ nanoparticles into PEEK increased the tensile strength and Young’s modulus of the FDM PEEK materials to similar levels to those achieved for unfilled injection moulded PEEK. Therefore, incorporation of IF-WS$_2$ nanoparticles into PEEK is a useful strategy to improve the mechanical performance of FDM PEEK.

Keywords: high-performance nanocomposite, additive manufacturing, injection moulding, PEEK (poly ether ether ketone), inorganic fullerene tungsten sulphide (IF-WS$_2$)
INTRODUCTION

Owing to their high thermal and chemical stability, exceptional strength-to-weight ratio, and recyclability, high performance thermoplastic polymers, such as Polysulfone (PSU), polyetherimide (PEI), and polyether ether ketone (PEEK) are becoming increasingly attractive in competition with metals and ceramics for load bearing applications under harsh operating conditions (Wiesli and Özcan, 2015; Al Christopher et al., 2021). Apart from the intrinsic properties of the polymer, the applied manufacturing method, processing conditions, and the material composition play a major role on the final quality and properties of high-performance thermoplastic parts (Golbang et al., 2017; Golbang et al., 2020; Liu and Kunc, 2020).

Nanofillers are added to polymers to further improve their thermal, mechanical and optical properties, depending on the type of filler (Aradhana et al., 2018; Golbang et al., 2020; Mokhtari et al., 2021a). For example, addition of hydroxyapatite particles increases the bioactivity of PEEK for development of cranial implants with improved biocompatibility (Manzoor et al., 2021). Incorporation of expanded graphite (EG) into PEEK via twin-screw compounding and injection moulding, results in significant enhancement of PEEK electrical conductivity (Mokhtari et al., 2021b).

The processing of high-performance polymers is generally more difficult and expensive compared with commodity thermoplastics due to their high melt viscosity and higher melting temperatures (Golbang et al., 2020). Incorporation of fillers into high-performance polymers for improving their performance may further increase melt viscosity thus creating potential problems in achieving sufficient power to process the material and risking thermal/shear degradation of the polymer. Therefore, the type, amount, and size of filler, as well as the processing method should be chosen carefully when developing high-performance nanocomposites (Diez-Pascual et al., 2012; Valino et al., 2019; Golbang et al., 2020; Mokhtari et al., 2021b; Manzoor et al., 2021).

Among the conventional plastics processing techniques, injection moulding is one of the most commonly used methods for production of high-performance polymers/ nanocomposites (Shaharuddin and Salit, 2006). Injection moulding enables large volume production with good precision, detail, and repeatability (Goodship, 2004; Shaharuddin and Salit, 2006; Bilewicz et al., 2008; Mokhtari et al., 2021b). When assessing the quality of parts produced via new polymer processing technologies such as additive manufacturing, they are often compared with those made via injection moulding. Additive manufacturing (AM) or 3D printing is becoming popular for producing parts from thermoplastic polymers as it can create complex geometries without the need for sophisticated tooling, resulting in cost-effective and sustainable manufacturing. Although, it should be noted that currently, AM is considered cost-effective for small volumes of production as compared to injection moulding (Dawoud et al., 2016; Köstial et al., 2016; Verdejo de Toro et al., 2020).

3D printing is mostly used for commodity plastics such as acrylonitrile butadiene styrene (ABS), and polyactic acid (PLA), polyvinyl alcohol (PVA), polycaprolactone (PCL), and polyamide (Nylon). However, the thermal and mechanical properties of these polymers are limited, and hence, there is growing demand to adopt AM processes to high-performance polymers for widespread commercial application. In recent years, high performance polymers have been successfully 3D printed via additive manufacturing techniques such as Fused Deposition Modelling (FDM) and High temperature selective laser sintering (HT-SLS). FDM is one of the most user-friendly and cost-effective AM methods for producing complex thermoplastic parts (Liu et al., 2019; Valino et al., 2019; Zanjani Jam et al., 2020). However, in comparison with conventional manufacturing methods, such as injection moulding, 3D printing results in lower part mechanical performance. This is mainly due to the weak inter-layer bonding between the deposited layers in FDM and presence of voids. For example, 3D printed Nylon six shows a tensile strength of ~50 MPa as compared with ~80 MPa for the injection moulded parts (Verdejo de Toro et al., 2020). Recently, much research has been conducted to improve the mechanical performance of 3D printed thermoplastics by adjusting and optimizing the printing conditions (i.e., layer thickness, print orientation, infill pattern, nozzle temperature, print bed temperatures, printing speed, etc) or addition of reinforcing particles such as silica, graphite, carbon, or glass fibres (Brucato et al., 1993; Pinto et al., 2015; Yang et al., 2017; Schiavone et al., 2020; Antony Samy et al., 2021). However, addition of fillers to the polymer feedstock is more challenging in FDM due to problems such as clogging of the nozzle, higher melt temperature and low flowability leading to poor chain inter-diffusion and therefore weaker inter-layer bonding as well as delamination. Hence, in order to achieve high quality printed parts, it is important to optimize the printing conditions according to the material flow properties, particle size, and the printer geometrical specification (e.g., nozzle diameter) (Coogan, 2019; Huang et al., 2019; Rostom and Dadmun, 2019; Srinivas et al., 2020; Candal et al., 2021).

To exploit the benefits of additive manufacturing and achieve 3D printed parts comparable with conventional manufacturing techniques such as injection moulding, it is crucial to resolve some of the associated issues with this technology, such as weak interlayer bonding. Hence, this study aims to improve the mechanical properties of 3D printed PEEK through incorporation of IF-WS2 nanoparticles. For this, PEEK nanocomposites with different loadings of IF-WS2 nanoparticles are produced using two methods: FDM and injection moulding. Then, the thermal and mechanical properties of the developed nanocomposites are evaluated and compared. As mentioned, PEEK is considered as a high-performance polymer with excellent thermal stability (up to 600°C), resistance to chemicals and radiation, as well as biocompatibility which makes it suitable for applications in aerospace, medical and automotive industries. IF-WS2 nanoparticles are very distinct types of fillers because of their innate mechanical and tribological properties, acting as both reinforcing and lubricating agents. In our previous research, it was shown that incorporation of IF-WS2 nanoparticles into
PEEK via melt compounding leads to reduction of melt viscosity which is favourable for processing without compromising its final mechanical properties (Golbang et al., 2020). It is believed that reduction of viscosity (improved flowability) can increase the bonding between the deposited layers through polymer chain diffusion and therefore improve the mechanical properties of the 3D-printed parts via FDM. Even though, reinforcing fillers generally increase the mechanical properties of the polymer, not all fillers can strengthen the interlayer bonding in FDM printed parts (Pinto et al., 2015; Coogan, 2019; Rostom and Dadmun, 2019; Srinivas et al., 2020). The objective of this study is to reduce the gap between the mechanical properties of the 3D-printed and injection moulded parts using IF-WS2 nanoparticles to address the low interlayer bonding strength FDM 3D-printed parts, as one of the prominent challenges in additive manufacturing.

**METHODOLOGY**

**Sample Preparation**

Inorganic fullerene like Tungsten di-sulfide (IF-WS2) nanoparticles with 80 nm average diameter were prepared by Professor Yanqui Zhu’s group at the University of Exeter. Polyether ether ketone (PEEK) 450 G was purchased from Victrex, \( M_w \approx 44,000 \text{ g/mol}, \ T_g \approx 143°C, \ T_m \approx 343°C \) and used as the matrix. To produce filaments for 3D printing, the IF-WS2 nanoparticles were melt compounded with PEEK at 0.5, 1, and 2 wt% loading using a twin-screw extruder with 16 mm diameter, length to diameter ratio (L/D) of 40, and screw speed of 30 rpm. The average diameter of filaments was monitored and kept at 1.75 ± 0.15 mm. The screw configuration was designed in a way to enhance nanoparticle dispersion using screw elements consisting of transporting elements for forward conveying of extrudate, kneading elements with 90°, 60°, and 30° twist angles for dispersion, and reverse screw element. The temperatures indicated in each zone of the extruder were: 365 (feeding zone), 400 (melting and compression zone), 385°C (metering zone and die extrusion). The extruded filaments were cooled at room temperature (~25°C).

A modified UM2 + FDM 3D printer was used for to print PEEK nanocomposite specimens which enables extrusion temperatures of up to 420°C (using an all-metal hot end), bed temperature of maximum 350°C (via heating elements embedded under the print bed), and heating lamps for regulation of chamber temperature up to 230°C.

Pellets were cut from the filaments for injection moulding. A Haake Minijet Pro injection moulding machine was used for production of injection moulded tensile samples, operating at melt temperature of 400°C and mould temperature of 280°C. Specimens with similar dimensions to the injection moulded samples were printed from the extruded filaments using a high temperature Ultimaker. The printing speed, building plate temperature, nozzle temperature and nozzle diameter were set at 40 mm/s, 280°C, 400°C and 2 mm, respectively. A raster orientation of ±45° was applied to produce a uniform morphology. A comparison was made between the mechanical properties of the printed and the injection moulded samples.

Pictures of the 3D-printed and injection moulded samples are presented in Figure 1.

The schematic presentation of the sequence of manufacturing process is demonstrated through a flowchart in Figure 2.

**Characterization**

A high resolution FEG SEM (HITACHI), operating at 30 kV and an intensity of \( 9 \times 10^{-9} \) was used to observe the gold coated
fractured surfaces of the filaments to evaluate the dispersion and distribution of IF-WS2 nanoparticles in PEEK.

The thermal properties of the 3D printed and injection moulded nanocomposite samples were measured using a TA-Instrument Q1000 differential scanning calorimeter (DSC). 5 mg samples were sealed in aluminium pans and a standard mode heating-cooling-heating cycle at 10°C/min between 20 and 400°C was applied. The amount of degree of crystallinity ($\chi_c$) was calculated from the crystallization peak (Golbang et al., 2020).

Tensile testing was performed on both 3D printed and injection moulded samples using an Instron testing machine (Instron 3,344) and following the ISO standard: ISO 527 in injection moulded samples using an Instron testing machine (Golbang et al., 2020; Antony Samy et al., 2021). Five specimens (75 mm × 4 mm × 2 mm) were tested for each sample with a crosshead speed of 2.0 mm/min at 20°C and using a 2 kN load cell.

RESULTS AND DISCUSSION

Scanning Electron Microscopy
The SEM images presented in Figure 3 show the morphology of PEEK nanocomposite filaments with 0.5, 1, and 2 wt% IF-WS2. Overall, a homogenous distribution of particles is observed in all three loadings. However, there is slightly larger sizes of inclusions present in the 2 wt% and to some extent in the 0.5 wt% samples, indicating some degree of agglomeration in these cases. The higher dispersion degree of particles achieved at 1 wt% IF-WS2 may be due to the lubricant effect of these nanoparticles. Tendency for agglomeration increases with further increase in the number of particles at the higher loading (2 wt%) (Khare and Burris, 2010; Golbang et al., 2017; Fu et al., 2019; Golbang et al., 2020).

There was no obvious change observed in the distribution and dispersion state of the nanoparticles after the injection moulding and 3D printing process.

Dispersion in a nanocomposite is associated with breaking of agglomerates into smaller sizes and ideally into individual nanoparticles, by overcoming the inter-particle interactions (typically van der Waals forces). The “dispersion state” of nanoparticles is linked to the final properties of the nanocomposite due to the long-range effects of nanoparticle-matrix interface on nearby polymer chains. However, achieving good dispersion is considered as a prominent challenge. The “distribution state” of particles in a nanocomposite is independent of dispersion state (or the size of inclusions). In a good distribution, the inclusions (e.g., particles, agglomerates, aggregates, …) are homogeneously distributed in the matrix and isotropic properties are achieved within the nanocomposite. In other words, each inclusion is as far as possible from its nearest neighbour, so that the space is homogeneously filled (Khare and Burris, 2010; Fu et al., 2019).

Thermal Properties
Changes in the crystallinity of the PEEK nanocomposites after extrusion (i.e., filaments), and shaped via 3D printing and injection moulding are shown in Figure 4.

Incorporation of IF-WS2 nanoparticles increases the crystallinity of PEEK in samples up to a loading of 1 wt% which can be attributed to the nucleation effect of these nanoparticles. Reduction of crystallinity with a further increase in IF-WS2 concentration to 2 wt%, is likely to be due to a reduced nucleation effect of the larger agglomerated IF-WS2 or a confining effect of the particles that restricts molecular mobility and ability of polymer chains to orient and crystallize (Golbang et al., 2020; Antony Samy et al., 2021).

From Figure 4, it can be seen that the overall crystallinity of the 3D printed samples is slightly higher at each filler loading compared with the injection moulded counterparts and filaments. This can be explained by the thermal history experienced in each process. During FDM, the deposited layers are reheated due to the deposition of subsequent layers. This multiple reheating effect contributes to further growth of crystals and higher degrees of crystallinity. During injection moulding, the material is cooled from extrusion temperature (400°C) to the mould temperature (280°C) in less than a minute and then ejected into a room temperature environment. The higher cooling rate in injection moulding compared to that in FDM, results in a lower degree of crystallinity. The filaments have the lowest degree of crystallinity at each filler loading. This is due to the sudden cool down of the polymer melt to room temperature (Brucato et al., 1993; Yang et al., 2017; Golbang et al., 2020; Schiavone et al., 2020; Antony Samy et al., 2021).

Mechanical Properties
The stress-strain curves of the injection moulded and 3D printed samples are illustrated in Figures 3, 4. The average Young’s modulus and ultimate tensile strength are reported in Table 1. As seen in
Figures 5, 6, as well as Table 1, the trend of changes in the Young’s modulus and tensile strength with addition of IF-WS2 nanoparticles are similar, with the addition of IF-WS2 nanoparticles generally increasing the Young’s modulus and tensile strength of PEEK up to a loading of 1 wt%. This increase is due to the presence of the reinforcing filler and the increased crystallinity of these samples. Properties drop off at the 2 wt% loading due to the stress concentration effect of, and lower aspect ratio of, agglomerated IF-WS2, combined with a slightly lower crystallinity. The elongation at break decreases in the injection moulded samples for increasing IF-WS2 which is quite typical when reinforcing fillers are added to a polymer matrix (Pinto et al., 2015; Huang et al., 2019; Rostom and Dadmun, 2019; Golbang et al., 2020). However, the reverse is true for the 3D printed materials with added IF-WS2. Two possible explanations for this improvement are an increase in layer-to-layer bonding due to enhanced thermal conductivity of IF-WS2 containing PEEK and, the lubricating effect of these nanoparticles, contributing to higher molecular mobility and polymer chain interdiffusion during deposition and therefore better bonding between the layers (Coogan, 2019; Srinivas et al., 2020; Candal et al., 2021).

The 3D printed samples have a lower Young’s modulus and tensile strength for each IF-WS2 loading in comparison to the injection moulded samples, by about 80 and 70%, respectively. There is a very significant reduction in elongation at break for the 3D printed materials compared to those that are injection moulded. These results are expected due to the weaker interlayer bonding between the layers in 3D printed samples and the presence of voids. Also, the pressure exerted during injection moulding can compress and strengthen the part (Koštial et al., 2016; Verdejo de Toro et al., 2020).

According to the data presented in Table 1, the Young’s modulus of the 3D printed samples containing 1 wt% IF-WS2 surpasses that of the injection moulded pure PEEK and the tensile strength is significantly increased to just 7% lower than the unfilled PEEK. Hence, it can be concluded that adding small amounts of IF-WS2 nanoparticles can overcome the reduced stiffness and tensile strength caused by poor layer adhesion and voids in 3D printed parts.
Overall, the increment in the Young’s Modulus and tensile strength of PEEK with addition of IF-WS$_2$ nanoparticles is higher for the 3D printed samples in respect to the injection moulded ones. This is ascribed to the improved bonding between the deposited PEEK layers in the presence of IF-WS$_2$ nanoparticles.

CONCLUSION

In this work, a comparison was made between the mechanical properties of high-performance PEEK nanocomposites with loadings of 0.5, 1, and 2 wt% IF-WS$_2$, fabricated by two different methods: injection moulding and 3D printing (FDM). Although the 3D printed samples had slightly higher levels of crystallinity compared with the injection moulded samples, they exhibited lower Young’s modulus and tensile strength as expected by about 82–87% and 73–85%, respectively. The lower mechanical properties of the 3D printed samples compared to their injection moulded counterparts is attributed to the lower packing density, poor inter-layer bonding and presence of voids. Overall, addition of IF-WS$_2$ nanoparticles increases the mechanical properties of PEEK in both 3D printed and injection moulded samples. However, it is worth noting that the presence of IF-WS$_2$ in PEEK reduces the gap between the mechanical properties of the 3D printed and injection moulded samples which can be ascribed to the simultaneous reinforcing and lubricating effect of these particles, allowing higher molecular inter-diffusion and better bonding between the layers.
