Abstract
With the abundance of automatic meeting transcripts, meeting summarization is of great interest to both participants and other parties. Traditional methods of summarizing meetings depend on complex multi-step pipelines that make joint optimization intractable. Meanwhile, there are a handful of deep neural models for text summarization and dialogue systems. However, the semantic structure and styles of meeting transcripts are quite different from articles and conversations. In this paper, we propose a novel abstractive summary network that adapts to the meeting scenario. We design a hierarchical structure to accommodate long meeting transcripts and a role vector to depict the difference among speakers. Furthermore, due to the inadequacy of meeting summary data, we pretrain the model on large-scale news summary data. Empirical results show that our model outperforms previous approaches in both automatic metrics and human evaluation. For example, on ICSI dataset, the ROUGE-1 score increases from 34.66% to 46.28%.

1 Introduction
Meetings are a very common forum where people exchange ideas, make plans, and share information. With the ubiquity of automatic speech recognition systems come vast amounts of meeting transcripts. Therefore, the need to succinctly summarize the content of a meeting naturally arises.

Several methods of generating summaries for meetings have been proposed (Mehdad et al., 2013; Murray et al., 2010; Wang and Cardie, 2013; Oya et al., 2014; Shang et al., 2018; Li et al., 2019). As Murray et al. (2010) points out, users prefer abstractive meeting summaries to extractive summaries. While these methods are mostly abstractive, they require complicated multi-stage machine learning pipelines, such as template generation, sentence clustering, multi-sentence compression, candidate sentence generation and ranking. As these approaches are not end-to-end optimisable, it is hard to jointly improve various parts in the pipeline to enhance the overall performance. Moreover, some components, e.g., template generation, require extensive human involvement, rendering the solution not scalable or transferrable.

Meanwhile, many end-to-end systems have been successfully employed to tackle document summarization, such as the pointer-generator network (See et al., 2017), reinforced summarization network (Paulus et al., 2018) and memory network
These deep learning methods can effectively generate abstractive document summaries by directly optimizing pre-defined goals.

However, the meeting summarization task inherently bears a number of challenges that make it more difficult for end-to-end training than document summarization. We show an example of a meeting transcript from the AMI dataset and the summary generated by our model in Table 1.

First, the transcript and summary of a single meeting are usually much longer than those of a document. For instance, in CNN/Daily Mail dataset (Hermann et al., 2015), there are on average 781 tokens per article and 56 tokens per summary, while AMI meeting corpus contains meetings with 4,757 tokens per transcript and 322 tokens per summary on average. And the structure of a meeting transcript is very distinct from news articles. These challenges all prevent existing news summarization models to be successfully applied to meetings.

Second, a meeting is carried out between multiple participants. The different semantic styles, viewpoints, and roles of each participant all contribute to the heterogeneous nature of the meeting transcript.

Third, compared with news, there is very limited labelled training data for meeting summary (137 meetings in AMI v.s. 312K articles in CNN/DM). This is due to the privacy of meetings and the relatively high cost of writing summaries for long transcripts.

To tackle these challenges, we propose an end-to-end deep learning framework, Hierarchical Meeting summarization Network (HMNet). HMNet leverages the encoder-decoder transformer architecture (Vaswani et al., 2017) to produce abstractive summaries based on meeting transcripts. To adapt the structure to meeting summarization, we propose two major design improvements.

First, as meeting transcripts are usually lengthy, a direct application of the canonical transformer structure may not be feasible. For instance, conducting the multi-head self-attention mechanism on a transcript with thousands of tokens is very time consuming and may cause memory overflow problem. Therefore, we leverage a hierarchical structure to reduce the burden of computing. As a meeting consists of utterances from different participants, it forms a natural multi-turn hierarchy. Thus, the hierarchical structure carries out both token-level understanding within each turn and turn-level understanding across the whole meeting. During summary generation, HMNet applies attention to both levels of understanding to ensure that each part of the summary stems from different portions of the transcript with varying granularities.

Second, to accommodate multi-speaker scenario, HMNet incorporates the role of each speaker\(^1\) to encode different semantic styles and viewpoints among participants. For example, a lead manager usually emphasizes the progress of the project while an interface designer tends to focus on user experience. In HMNet, we train a role vector for each meeting participant to represent the speaker’s information during encoding. This role vector is appended to the turn-level representation for later decoding.

To tackle the problem of insufficient training data for meeting summarization, we leverage the idea of pretraining (Devlin et al., 2018). We collect summarization data from the news domain and convert them into the meeting format: a group of several news articles forms a multi-person meeting and each sentence becomes a turn. The turns are reshuffled to simulate a mixed order of speakers. We pretrain the HMNet model on the news task before finetuning it on meeting summarization. Empirical results show that this cross-domain pretraining can effectively enhance the model quality.

To evaluate our model, we employ the widely used AMI and ICSI meeting corpus (McCowan et al., 2005; Janin et al., 2003). Results show that HMNet significantly outperforms previous meeting summarization methods. For example, on ICSI dataset, HMNet achieves 11.62 higher ROUGE-1 points, 2.60 higher ROUGE-2 points, and 6.66 higher ROUGE-SU4 points compared with the previous best result. Human evaluation further show that HMNet generates much better summaries than baseline methods. We then conduct ablation studies to verify the effectiveness of different components in our model.

### 2 Problem Formulation

We formalize the problem of meeting summarization as follows. The input consists of meeting transcripts \( X \) and meeting participants \( P \). Suppose there are \( s \) meetings in total. The tran-\(^1\)Both datasets in experiments only provide role information for each participant. In real applications, we can use a vector to represent each participant when a personal identifier is available.
scripts are \( X = \{X_1, ..., X_s\} \). Each meeting transcript consists of multiple turns, where each turn is the utterance of a participant. Thus, \( X_i = \{(p_1, u_1), (p_2, u_2), ..., (p_{L_i}, u_{L_i})\} \), where \( p_j \in \mathcal{P}, 1 \leq j \leq L_i \), is a participant and \( u_j = (w_1, ..., w_{t_j}) \) is the tokenized utterance from \( p_j \). The human-labelled summary for meeting \( X_i \), denoted by \( Y_i \), is also a sequence of tokens. For simplicity, we will drop the meeting index subscript. So the goal of the system is to generate meeting summary \( Y = (y_1, ..., y_n) \) given the transcripts \( X = \{(p_1, u_1), (p_2, u_2), ..., (p_m, u_m)\} \).

3 Model

Our hierarchical meeting summarization network (HMNet) is based on the encoder-decoder transformer structure (Vaswani et al., 2017), and its goal is to maximize the conditional probability of meeting summary \( Y \) given transcript \( X \) and network parameters \( \theta \): \( P(Y|X; \theta) \).

3.1 Encoder

3.1.1 Role Vector

Meeting transcripts are recorded from various participants, who may have different semantic styles and viewpoints. Therefore, the model has to take the speaker’s information into account while generating summaries.

To incorporate the participants’ information, we integrate the speaker role component. In the experiments, each meeting participant has a distinct role, e.g., program manager, industrial designer. For each role, we train a vector to represent it as a fixed-length vector \( r_p \), where \( P \) is the number of roles. Such distributed representation for a role/person has been proved to be useful for sentiment analysis (Chen et al., 2016). This vector is appended to the embedding of the speaker’s turn (Section 3.1.2). According to the results in Section 4.5, the vectorized representation of speaker roles plays an important part in boosting the performance of summarization.

This idea can be extended if richer data is available in practice:

- If an organization chart of participants is available, we can add in representations of the relationship between participants, e.g., manager and developers, into the network.
- If there is a pool of registered participants, each participant can have a personal vector which acts as a user portrait and evolves as more data about this user is collected.

3.1.2 Hierarchical Transformer

Transformer. Recall that a transformer block consists of a multi-head attention layer and a feed-forward layer, both followed by layer-norm with residuals: \( \text{LayerNorm}(x + \text{Layer}(x)) \), where \( \text{Layer} \) can be the attention or feed-forward layer (Vaswani et al., 2017).

As the attention mechanism is position agnostic, we append positional encoding to input vectors:

\[
\begin{align*}
\text{PE}_{(i,j)} &= \sin(i/10000^{2j}) \\
\text{PE}_{(i,j+1)} &= \cos(i/10000^{2j}),
\end{align*}
\]

where \( \text{PE}_{(i,j)} \) stands for the \( j \)-th dimension of positional encoding for the \( i \)-th word in input sequence. We choose sinusoidal functions as they can extend to arbitrary input length during inference.

In summary, a transformer block on a sequence of \( n \) input embeddings can generate \( n \) output embeddings of the same dimension as input. Thus, multiple transformer blocks can be sequentially stacked to form a transformer network:

\[
\text{Transformer}\{x_1, ..., x_n\} = \{y_1, ..., y_n\}
\]

Long transcript problem. As the canonical transformer has the attention mechanism, its computational complexity is quadratic in the input length. Thus, it struggles to handle very long sequences, e.g. 5,000 tokens. However, meeting transcripts are usually fairly long, consisting of thousands of tokens.

We note that meetings come with a natural multi-turn structure with a reasonable number of turns, e.g. 289 turns per meeting on average in AMI dataset. And the number of tokens in a turn is much less than that in the whole meeting. Therefore, we employ a two-level transformer structure to encode the meeting transcript.

Word-level Transformer. The word-level transformer processes the token sequence of one turn in the meeting. We encode each token in one turn using a trainable embedding matrix \( D \). Thus, the \( j \)-th token in the \( i \)-th turn, \( w_{i,j} \), is associated with a uniform length vector \( D(w_{i,j}) = g_{i,j} \). To incorporate syntactic and semantic information, we also train two embedding matrices to represent the part-of-speech (POS) and entity (ENT) tags. Therefore, the token \( w_{i,j} \) is represented by the vector
\[ x_{i,j} = [g_{i,j}; \text{POS}_{i,j}; \text{ENT}_{i,j}] \]. Note that we add a special token \( w_{i,0} = \text{[BOS]} \) before the sequence to represent the beginning of a turn. Then, we denote the output of the word-level transformer as follows: \( \text{Word-Transformer}(\{x_{i,0}, \ldots, x_{i,L_i}\}) = \{x^W_{i,0}, \ldots, x^W_{i,L_i}\} \).

**Turn-level Transformer.** The turn-level transformer processes the information of all \( m \) turns in a meeting. To represent the \( i \)-th turn, we employ the output embedding of the special token \( \text{[BOS]} \) from the word-level transformer, i.e. \( x^W_{i,0} \). Furthermore, we concatenate it with the role vector of the speaker for this turn, \( p_i \). It follows that the output of the turn-level transformer is:

\[
\text{Turn-Transformer}(\{[x^W_{1,0}; p_1], \ldots, [x^W_{m,0}; p_m]\}) = \{x^T_1, \ldots, x^T_m\}.
\]

### 3.2 Decoder

The decoder is a transformer to generate the summary tokens. The input to the decoder transformer contains the \( k - 1 \) previously generated summary tokens \( \hat{y}_1, \ldots, \hat{y}_{k-1} \). Each token is represented by a vector using the same embedding matrix \( D \) as the encoder, \( D(\hat{y}_i) = g_i \).

The decoder transformer uses a lower triangular mask to prevent the model to look at future tokens. Moreover, the transformer block includes two cross-attention layers. After self-attention, the embeddings first attend with token-level outputs \( \{x^W_{i,j}\}_{i=1,j=1}^m \), and then with turn-level outputs \( \{x^T_i\}_{i=1}^m \), each followed by layer-norm. This makes the model attend to different parts of the inputs with varying scales at each inference step.

The output of the decoder transformer is denoted as: \( \text{Decoder-Transformer}(\{g_1, \ldots, g_{k-1}\}) = \{v_1, \ldots, v_{k-1}\} \).

To predict the next token \( \hat{y}_k \), we reuse the weight of embedding matrix \( D \) to decode \( v_{k-1} \) into a probability distribution over the vocabulary:

\[
P(\hat{y}_k | y_{<k}, X) = \text{softmax}(v_{k-1}D^T)
\]

We illustrate the Hierarchical Meeting Summary Network (HMNet) in Fig. 1.

**Training.** During training, we seek to minimize the cross entropy:

\[
L(\theta) = -\frac{1}{n} \sum_{k=1}^{n} \log P(y_k | y_{<k}, X)
\]
We use teacher-forcing in decoder training, i.e. the decoder takes ground-truth summary tokens as input.

**Inference.** During inference, we use beam search to select the best candidate. The search starts with the special token \(\text{BEGIN}\). We employ the commonly used trigram blocking (Paulus et al., 2018): during beam search, if a candidate word would create a trigram that already exists in the previously generated sequence of the beam, we forcibly set the word’s probability to 0. Finally, we select the summary with the highest average log-likelihood per token.

### 3.3 Pretraining

As there is limited availability of meeting summarization data, we propose to utilize summary data from the news domain to pretrain HMNet. This can warm up model parameters on summarization tasks. However, the structure of news articles is very different from meeting transcripts. Therefore, we transform news articles into the meeting format.

We concatenate every \(M\) news articles into an \(M\)-people meeting, and treat each sentence as a single turn. The sentences from article \(i\) is considered to be utterances from the \(i\)-th speaker, named as \([\text{Dataset-}i]\). For instance, for each XSum meeting, the speakers’ names are \([\text{XSum-}1]\) to \([\text{XSum-}\ M]\). To simulate the real meeting scenario, we randomly shuffle all the turns in these pseudo meetings. The target summary is the concatenation of the \(M\) summaries.

We pretrain HMNet model with a large collection of news summarization datasets CNN/DailyMail (Hermann et al., 2015), NYT (Sandhaus, 2008) and XSum (Narayan et al., 2018), containing 312K, 104K and 227K article-summary pairs. We take the union of three datasets for the pretraining. We choose groups of \(M = 4\) news articles to match the 4-speaker setting in AMI dataset. These converted meetings contain on average 2,812 words with 128 turns and 176 words in the summary.

### 4.2 Baseline models

For comparison, we select a variety of baseline systems from previous literatures: the basic baselines Random (Riedhammer et al., 2008) and Copy from Train, which randomly copies a summary from the training set as the prediction; the template-based method Template (Oya et al., 2014); the ranking systems TextRank (Mihalcea and Tarau, 2004) and ClusterRank (Garg et al., 2009); the unsupervised method UNS; the document summarization model PGNet (See et al., 2017); and the multi-modal model MM (Li et al., 2019).

In addition, we implement the baseline model Extractive Oracle, which concatenates top sentences with the highest ROUGE-1 scores with the golden summary. The number of sentences is determined by the average length of golden summary: 18 for AMI and 23 for ICSI.

---

**Footnotes:**

1. We select the Scenario Meetings of AMI as in Shang et al. (2018)
2. To reduce variance, for each article, we randomly sample 50 times and report the averaged metrics.
3. PGNet treats the whole meeting transcript as an article and generates the summary.
Table 2: ROUGE-1, ROUGE-2, ROUGE-SU4 scores of generated summary in AMI and ICSI datasets. Numbers in bold are the overall best result. * The two baseline MM models require additional human annotations of topic segmentation and visual signals from cameras. ** Results are statistically significant at level 0.05.

4.3 Metrics
Following Shang et al. (2018), we employ ROUGE-1, ROUGE-2 and ROUGE-SU4 metrics (Lin, 2004) to evaluate all meeting summarization models. These three metrics respectively evaluate the accuracy of unigrams, bigrams, and unigrams plus skip-bigrams with a maximum skip distance of 4. These metrics have been shown to highly correlate with the human judgment (Lin, 2004).

4.4 Implementation Details
We employ spaCy (Honnibal and Johnson, 2015) as the word tokenizer and embed POS and NER tags into 16-dim vectors. The dimension of the role vector is 32.

All transformers have 6 layers and 8 heads in attention. The dimension for each word is 512 and thus the input and output dimensions of transformers \(d_{model}\) are 512 for the decoder, \(512 + 16 + 16 = 544\) for the word-level transformer, and \(512 + 16 + 16 + 32 = 576\) for the turn level transformer. For all transformers, the inner-layer always has dimensionality \(d_{ff} = 4 \times d_{model}\). HMNet has 204M parameters in total. We use a dropout probability of 0.1 on all layers.

We pretrain HMNet on news summarization data using the RAdam optimizer (Liu et al., 2020) with \(\beta_1 = 0.9, \beta_2 = 0.999\). The initial learning rate is set to \(1e-9\) and linearly increased to 0.001 with 16000 warmup steps. For finetuning on the meeting data, the optimization setup is the same except the initial learning rate is set to 0.0001. We use gradient clipping with a maximum norm of 2 and gradient accumulation steps as 16.

4.5 Results
Table 2 shows the ROUGE scores of generated summaries in AMI and ICSI datasets. As shown, except for ROUGE-1 in AMI, HMNet outperforms all baseline models in all metrics, and the result is statistically significant at level 0.05, under paired t-test with the best baseline results. On ICSI dataset, HMNet achieves 11.62, 2.60 and 6.66 higher ROUGE points than previously best results. Note that MM is a multi-modal model which requires human annotation of topic segmentation (TopicSeg) and visual focus on attention (VFOA) collected from cameras, which is rarely available in practice. In comparison, our model HMNet is entirely based on transcripts from ASR pipelines. Still, on AMI dataset, HMNet outperforms MM(TopicSeg) by 1.49 points in ROUGE-1 and 6.34 points in ROUGE-2, and is higher than MM(TopicSeg+VFOA) by 5.06 points in ROUGE-2.

Moreover, HMNet significantly outperforms the document summarization model PGNet, indicating that traditional summarization models must be carefully adapted to meeting scenarios. HMNet also compares favorably to the extractive oracle, showing that human summaries are more abstractive rather than extractive for meetings.

It’s worth noting that Copy from Train obtains a surprisingly good result in both AMI and ICSI, higher than most baselines including PGNet. The reason is that the meetings in AMI and ICSI are
not isolated events. Instead, they form a series of related discussions on the same project. Thus, many project keywords appear in multiple meetings and their summaries. It also explains the relatively high ROUGE scores in the evaluation. However, HMNet can focus on salient information and as a result, achieves a considerably higher score than Copy from Train baseline.

**Ablation Study.** Table 3 shows the ablation study of HMNet on the test set of AMI and ICSI. As shown, the pretraining on news summarization data can help increase the ROUGE-1 on AMI by 4.3 points and on ICSI by 4.0 points. When the role vector is removed, the ROUGE-1 score drops 5.2 points on AMI and 2.3 points on ICSI. When HMNet is without the hierarchy structure, i.e. the turn-level transformer is removed and role vectors are appended to word-level embeddings, the ROUGE-1 score drops as much as 7.9 points on AMI and 5.3 points on ICSI. Thus, all these components we propose both play an important role in the summarization capability of HMNet.

### 4.6 Human Evaluation

We conduct a human evaluation of the meeting summary to assess its readability and relevance. Readability measures how fluent the summary language is, including word and grammatical error rate. Relevance measures how well the summary sums up the main ideas of the meeting.

As MM model (Li et al., 2019) does not have summarization text or trained model available, we compare the results of HMNet and UNS (Shang et al., 2018). For each meeting in the test set of AMI and ICSI, we have 5 human evaluators from Amazon Mechanical Turk label summaries from HMNet and UNS. We choose labelers with high approval rating (>98%) to increase the credibility of results.

Each annotator is presented with the meeting transcript and the summaries. The annotator needs to give a score from 1 to 5 (higher is better) for readability (whether the summary consists of fluent and coherent sentences and easy to understand) and likewise for relevance (whether the summary contains important information from the meeting). The annotators need to read both the meeting transcript and the summary to give evaluations. To reduce bias, for each meeting, the two versions of summaries are randomly ordered.

Table 4 shows that HMNet achieves much higher scores in both readability and relevance than UNS in both datasets. And the scores for HMNet are all above 4.0, indicating that it can generate both readable and highly relevant meeting summaries.

### 5 Insights

#### 5.1 How abstractive is our model?

An abstractive system can be innovative by using words that are not from the transcript in the summary. Similar to See et al. (2017), we measure the

| Dataset | AMI |
|---------|-----|
| Source  | HMNet | UNS |
| Readability | 4.17 (.38) | 2.19 (.57) |
| Relevance | 4.08 (.45) | 2.47 (.67) |

| Dataset | ICSI |
|---------|-----|
| Source  | HMNet | UNS |
| Readability | 4.24 (.20) | 2.08 (.20) |
| Relevance | 4.02 (.55) | 1.75 (.61) |

Table 4: Average scores (1-5) of readability and relevance of summaries on AMI and ICSI’s test sets. Each summary is judged by 5 human evaluators. Standard deviation is shown in parenthesis.
abstractiveness of a summary model via the ratio of novel words or phrases in the summary. A higher ratio could indicate a more abstractive system.

Fig. 2 displays the percentage of novel n-grams, i.e. that do not appear in the meeting transcript, in the summary from reference, HMNet, and UNS. As shown, both reference and HMNet summaries have a large portion of novel n-grams ($n > 1$). Almost no 4-grams are copied from the transcript. In contrast, UNS has a much lower ratio of novel n-grams, because it generates a summary mainly from the original word sequence in transcripts.

5.2 Error Analysis

We qualitatively examine the outputs of HMNet and summarize two major types of errors:

1. Due to the nature of long meeting transcripts, the system sometimes summarizes salient information from parts of the meeting different from the reference summaries.

2. Our system sometimes summarizes meetings at a high level (e.g. topics, decisions) and not to cover all detailed items as in the reference.

6 Related Work

**Meeting Summarization.** There are a number of studies on generating summaries for meetings and dialogues (Zhao et al., 2019; Liu and Chen, 2019; Chen and Metze, 2012; Liu et al., 2019b,a). Mehdad et al. (2013) uses utterance clustering, an entailment graph, a semantic word graph and a ranking strategy to construct meeting summaries. Murray et al. (2010) and Wang and Cardie (2013) focus on various aspects of meetings such as decisions and action items. Oya et al. (2014) employs multi-sentence fusion to construct summarization templates for meetings, leading to summaries with higher readability and informativeness. Recently, Shang et al. (2018) leverages a multi-sentence compression graph and budgeted submodular maximization to generate meeting summaries. In general, these multi-step methods make joint optimization intractable. Li et al. (2019) proposes an encoder-decoder structure for end-to-end multimodal meeting summarization, but it depends on manual annotation of topic segmentation and visual focus, which may not be available in practice. In comparison, our model only requires meeting transcripts directly from speech recognition.

**Document Summarization.** Rush et al. (2015) first introduces an attention-based seq2seq (Sutskever et al., 2014) model to the abstractive sentence summarization task. However, the quality of the generated multi-sentence summaries for long documents is often low, and out of vocabulary (OOV) words cannot be efficiently handled. To tackle these challenges, See et al. (2017) proposes a pointer-generator network that can both produce words from the vocabulary via a generator and copy words from the source text via a pointer. Paulus et al. (2018) further adds reinforcement learning to improve the result. Gehrmann et al. (2018) uses a content selector to over-determine phrases in source documents that helps constrain the model to likely phrases and achieves state-of-the-art results in several document summarization datasets. Recently several works on using large-scale pretrained language models for summarization are proposed and achieves very good performance (Liu, 2019; Devlin et al., 2018; Raffel et al., 2019; Lewis et al., 2019; Zhang et al., 2019).

**Hierarchical Neural Architecture.** As a variety of NLP data (e.g., conversation, document) has an internal hierarchical structure, there have been many works applying hierarchical structures in NLP tasks. Li et al. (2015) proposes a hierarchical neural auto-encoder for paragraph and document reconstruction. It applies two levels of RNN: one on tokens within each sentence and the other on all sentences. Lin et al. (2015) applies a hierarchical RNN language model (HRNNLM) to document modeling, which similarly encodes token-level and turn-level information for better language modeling performance. Serban et al. (2016) puts forward a hierarchical recurrent encoder-decoder network (HRED) to model open-domain dialogue systems and generate system responses given the previous context. Nallapati et al. (2016) proposes the hierarchical attention mechanism on word-level and turn-level in the encoder-decoder structure for abstractive document summarization.

7 Conclusion

In this paper, we present an end-to-end hierarchical neural network, HMNet, for abstractive meeting summarization. We employ a two-level hierarchical structure to adapt to the long meeting transcript, and a role vector to represent each participant. We also alleviate the data scarcity problem by pretraining on news summarization data. Experiments show that HMNet achieves state-of-the-art performance in both automatic metrics and human evalu-
ation. Through an ablation study, we show that the role vector, hierarchical architecture, and pretraining all contribute to the model’s performance.

For future work, we plan to utilize organizational chart, knowledge graph and topic modeling to generate better meeting summaries, which can better capture salient information from the transcript.

Table 5: Selected hyperparameters and development set rouge scores for the reported performance in table 2

|       | Min. Len. | Beam Size | R-1 (Dev) | R-1 (Test) | R-2 (Dev) | R-2 (Test) |
|-------|-----------|-----------|-----------|------------|-----------|------------|
| AMI   | 400       | 6         | 49.50     | 17.01      | 22.74     |
| ICSI  | 280       | 6         | 48.96     | 11.34      | 19.62     |

Table 6: Hyperparameter search trials of minimum generation length with beam size fixed as 3. The bold numbers are the best development set performance with the selected minimum generation length.

|       | AMI         |           | ICSI        |           |
|-------|-------------|-----------|-------------|-----------|
| Min. Len. | R-1 (Dev) | R-1 (Test) | R-1 (Dev) | R-1 (Test) |
| 240    | 47.41      | 52.82     | 48.98      | 45.68     |
| 280    | 47.75      | 53.05     | 47.12      | 45.68     |
| 320    | 48.03      | 53.11     | 46.88      | 45.68     |
| 360    | 48.52      | 52.31     | 46.90      | 45.68     |
| 400    | **48.68**  | 51.40     | 46.27      | 46.10     |
| 440    | 48.39      | 50.35     | 45.68      | 45.82     |

Table 7: Hyperparameter search trials of beam size with minimum generation length fixed with 400 for AMI and 280 for ICSI. The bold numbers are the best development set performance with the selected beam size. "N/A" in the table is due to the GPU memory overflow issue for large beam size.

|       | AMI         |           | ICSI        |           |
|-------|-------------|-----------|-------------|-----------|
| Beam Size | R-1 (Dev) | R-1 (Test) | R-1 (Dev) | R-1 (Test) |
| 1      | 48.09      | 50.97     | 45.13      | 45.54     |
| 3      | 48.68      | 51.40     | 47.12      | 45.68     |
| 6      | **49.50**  | 53.02     | **48.96**  | 46.28     |
| 8      | 49.42      | N/A       | 48.12      | 46.35     |
| 9      | N/A        | N/A       | 48.35      | 45.45     |
| 10     | N/A        | N/A       | 47.72      | 45.88     |

Table 5: Selected hyperparameters and development set rouge scores for the reported performance in table 2

A Training Details

All the training is conducted on 4 Tesla V-100 GPU with 32G memory. The batch size per GPU is 4096 tokens during pretraining and 8300 during finetuning. The pretraining converges after 300,000 steps, which runs for approximately 4 days. The finetuning for both meeting datasets converges after 20,000 steps, which runs for 6 hours. We pick the model with the highest ROUGE-1 score on the development set of news and meeting datasets for pretraining and finetuning, respectively. The ROUGE scores are computed using the open-source implementation.

Due to the large computation cost of pretraining, we only tune hyperparameters for the decoding, namely the minimum length of the generated summary and beam size. For both AMI and ICSI, we first set beam size to 3 and grid search the minimum length from {240, 280, 320, 360, 400, 440}. After selecting the best minimum length, we tune the beam size from {1, 3, 6, 8, 9, 10}. The tuning is based on the development set ROUGE-1 score. The selected hyperparameters for AMI and ICSI and the corresponding development set performance is shown in table 5. All hyperparameter search trials and development/test set performance could be found in table 6 and 7.

7https://github.com/andersjo/pyrouge/tree/master/tools/ROUGE-1.5.5

B Example of Meeting Summary

We demonstrate in Table 8, Table 9 and Table 10 examples of AMI meeting transcript with speaker information and three versions of summaries: reference, HMNet and UNS (Shang et al., 2018). Since the transcript results are from ASR pipelines, there are some word errors and grammatical glitches. Moreover, compared with document summarization tasks like CNN/Daily Mail (Hermann et al., 2015; Nallapati et al., 2016), the meeting transcript is pretty long and lacks the important-information-first structure. All of these add to the complexity of meeting summarization tasks.

The summary generated by HMNet includes both individual actions/proposals and group activities, which is similar to the reference. In contrast, the result from UNS does not have a clear structure. Also, HMNet is more effective in selecting salient information from the lengthy transcript. Furthermore, the language of summary from HMNet is smoother and has many fewer grammatical errors than UNS. The reason is that HMNet learns the language pattern from the reference summary during training while UNS generates summaries by concatenating transcript word sequences.
Meeting Transcript (163 turns)

ME: ... I've done some research. We have we have been doing research in a usability lab where we observed users operating remote controls. we let them fill out a questionnaire. Remotes are being considered ugly. F seventy five percent of the people questioned indicated that they thought their remote were was ugly. and an additional eighty percent indicated that they would spend more money on a fancy-looking remote control. Fifty percent of the people indicated they only loo used about ten percent of the buttons on a remote control ...

ID: I've got a presentation about the working design. first about how it works. It’s really simple. Everybody knows how a remote works. The user presses a button. The remote determines what button it is, uses the infrared to send a signal to the TV ... they only use about ten percent of the buttons, we should make very few buttons ...

PM: ... another point is we have to skip the teletext, because in the world of upcoming internet we think teletext is going to be a thing of the past. And it’s a function we don’t need in our remote control...

...

UI: But Got many functions in one remote control, you can see, this is quite simple remote control. few buttons but This re remote control got a lot of buttons. people don’t like it, so what I was thinking about was keep the general functions like they are.

PM: Extra button info. that should be possible as. let’s see what did we say. More. Should be fancy to, fancy design, easy to learn. Few buttons, we talked about that. Docking station, LCD. general functions And default materials... And we have to be very atten in putting the corporate image in our product. So it has to be visible in our design, in the way our device works...

...

PM: ... I will put the minutes in the project document folder... And we have a lunch-break now.

Reference Summary (14 sentences)

The Project Manager stated the agenda and the marketing expert discussed what functions are most relevant on a remote, what the target demographic is, and what his vision for the appearance of the remote is.

The Marketing Expert also brought up the idea to include a docking station to prevent the remote from getting lost and the idea to include an LCD screen.

The User Interface Designer pushed for a user interface with large buttons, a display function, a touchscreen, and the capability of controlling different devices.

The team then discussed teletext, the target demographic, the buttons the remote should have, the idea of marketing a remote designed for the elderly, an audio signal which can sound if the remote is lost, LCD screens, and language options.

Whether to include teletext in the design despite the new requirement which indicates that the team is not to work with teletext.

The buttons are generally used, but the main feature is ugly and ugly.

The remote will only have a few buttons.

The remote will feature a small LCD screen.

The remote will have a docking station.

...

Summary from HMNet (ours, 23 sentences)

The User Interface Designer and the Industrial Designer presented the components of a remote control device.

The Marketing Expert presented research on the working design and selling buttons for the next meeting.

The Industrial Designer gave a presentation of the functions of the remote.

The Project Manager announced that the project would not include a teletext feature.

The Project Manager will post the minutes per cent of the minutes.

The User Interface Designer will focus on the corporate image of the company.

The group decided on features to include in the remote, to include an LCD screen, and a docking station to change the layout of the interface.

...

The remote will have buttons as few buttons as possible.

Whether to include docking station selection for it.

What functions the remote should be.

Summary from UNS (8 sentences)

Buttons we talked about the docking station LCD general functions
Fancy design easy to learn few buttons on the right places
Simple manner to put a lot of functions of the remote control
Pricing we need a great deal of people would indicated that an LCD screen in the remote control would be preferred
Focusing on elderly people or people forty plus they wanted to work
Seventy five percent of the people indicated that the remote got lost in the room
Minimum number of buttons the real buttons we have to use rebecca
Required so most existing remote control simply

Table 8: Example meeting transcript in AMI and summary from reference, HMNet, and UNS. Roles of participants are coded as follows: PM - project manager, ME - marketing expert, ID - industrial designer, UI - user interface designer. We manually capitalize some words in the summaries from HMNet and UNS for better demonstration.
PM: ... It’s the conceptual design meeting. And a few points of interest in this meeting are the conceptual specification of components, conceptual specification of design. And also trend-watching ...
ME: Doh. I’m gonna inform you about the trend-watching I’ve done over the past few days. we’ve done some market research. We distributed some more enquetes, questionnaires ...
UI: ... And we need some new a attractive functions which attract people for using it. it’s like a speak speech recognition and a special button for selecting subtitles. and overall user-friendly, using large buttons ...
ID: About the components design. for the energy source we can use a basic battery or, a as an optional thing, a kinetic energy, like in a watch ... for the casing, the manufacturing department can deliver a flat casing, single or double curved casing ... And the chip-set really should be advanced because ...
...
ID: Let’s look at the flat case. It’s from the side so it’s rather normal. The the single curved so I’m not really what they’re gonna look like, but it’s something like this. this type should be better for you or better Should prevent repetitive strain injury a bit ...
PM: I suggest the single curved, because maybe the curve is pretty good to put the screen in ...
UI: And to put the buttons for changing the channel over here
UI: Maybe it’s possible to make this side like Let’s see. Colour to make this side like the right colour ...
...
PM: ... The user interface design, it’s the same story. And product evaluation. So the Industrial Designer and User Interface Designer are going to work together on this one ...

Reference Summary (18 sentences)
The Project Manager opened the meeting and recapped the decisions made in the previous meeting.
The Marketing Expert discussed his personal preferences for the design of the remote and presented the results of trend-watching reports, which indicated that there is a need for products which are fancy, innovative, easy to use, in dark colors, in recognizable shapes, and in a familiar material like wood.
The User Interface Designer discussed the option to include speech recognition and which functions to include on the remote.
The Industrial Designer discussed which options he preferred for the remote in terms of energy sources, casing, case supplements, buttons, and chips.
The team then discussed and made decisions regarding energy sources, speech recognition, LCD screens, chips, case materials and colors, case shape and orientation, and button orientation.

Summary from HMNet (ours, 21 sentences)
The Project Manager opened the meeting by conceptual components and conceptual design.
The Industrial Designer discussed the interior workings of a remote and suggested that the remote should feature speech recognition.
The User Interface Designer presented two existing products and discussed the option to design a remote for the docking station.
The Marketing Expert discussed research from trend watchers.
The trend watchers have been consulted about energy sources, such as voice recognition, speech recognition, case recognition, and overall buttons.
They also discussed the possibility of using a flat, double curved case, and double curved or double curved cases.
The group discussed the options for energy source, and energy sources.
The designers will work together on the prototype evaluation.

Summary from UNS (9 sentences)
Older people like to shake your remote control the fresh Changing channels button on the right side
Time look easily get screen would held in making the remote control easier
Leads us to some personal preferences the remote control
People would pay more for speech recognition in a remote control
Research about the designing a fly interface designer are going to work
Trendwatchers i consulted advise that it should be the remote control on the docking station should be telephone shape so you could imagine
Start by choosing a case
Show it people like wood but it raised the price

Table 9: Example of meeting transcript and summary from reference, HMNet, and UNS.
Meeting Transcript (245 turns)

PM: ... I’ll go over what we decided last meeting.
ID: this is the working design, presented by me. What the first thing question I asked was what are we trying to design?, a device which just sends the signal to the TV to change its state, whether that be the power, or the channel or the volume...
UI: ... But we are to make it unique so that people want to buy it, will this two features together. So what the concept is to have a flip-top model... Findings most people prefer us user-friendly rather than complex remote controls... I would make flip-top with a trendy design.
ME: ... Eighty percent would spend more money when a remote control would look fancy... are prepared to spend more money for something that’s a bit nicer looking... current remote controls do not match with the operating behaviour of the user overall.
...
ME: We asked those two questions, the table relates to both questions, so we didn’t differentiate. Would you prefer an LCD screen, that’s multi-function remote and would you pay more for speech recognition in a remote control? ...
ME: Do we have to initially, looking at the findings here, focus on a younger age group initially and then broaden out the market later. Do we really have to go for everyone right away?
UI: We could focus on the biggest market. If say people between age group of twenty to thirty five are the biggest market?
...

Reference Summary (25 sentences)
The Industrial Designer gave his presentation on the basic functions of the remote. He presented the basic components that remotes share and suggested that smaller batteries be considered in the product design.
The User Interface Designer presented his ideas for making the remote easy-to-use; he discussed using a simple design and hiding complicated features from the main interface.
The Marketing Expert presented the findings from a lab study on user requirements for a remote control device, and discussed users’ demand for a simple interface and advanced technology.
The Project Manager presented the new requirements that the remote not include a teletext function, that it be used only to control television, and that it include the company image in its design.
The group narrowed down their target marketing group to the youth market.
The group then discussed the shell-like shape of the remote and including several different casing options to buyers. The remote will be bundled with a docking station to recharge the remote’s batteries and a user-friendly instruction manual, and multiple casings will be made available.
The limitations of the budget will restrict the development of some features; several of the features that the group wanted to include may have to be made simpler to decrease cost.

Summary from HMNet (ours, 25 sentences)
The Project Manager recapped the decisions made in the previous meeting. The Industrial Designer discussed the interior workings of a remote and the team discussed options for batteries, volume control, and LCD screens.
The Marketing Expert also found that users want a fancy look and feel, trendy, fashionable, and user design.
The User Interface Designer presented findings from trend watching reports which indicated a need for products which are technologically innovative, are attractive to a user.
The group decided to include a flip and an LCD screen, and discussed how well the interface would be incorporated into it.
The team then discussed how to minimize the number of functions and what functions to include in their design.
They discussed making the remote a profit target group and whether to include an LCD, ease of noise, voice recognition, a locator function, and the LCD screen.
The Marketing Expert will focus on making the product more user as possible to compensate younger consumers. The remote will only have a small, trendy design, and will have a few buttons for the next meeting.

Summary from UNS (9 sentences)
Important that the project was accessible to wide range of consumers white age groups Remote you gotta press a button on top the tv and it beeps Seventy five percent of user find most remote controls Point about pressing the pound sign of the bleep are in the room Stick them in a program have to control with this remote control Hold in the palm of the hand set for all tv it here occur Fair amount i run that it last a long time Change the state of the tv all other appliances sending a signal Market research at
