Abstract

Background

We revise the genus *Metaplagia* Coquillett, 1895 and describe five new species from Area de Conservación Guanacaste (ACG) in northwestern Costa Rica. All new species were reared from an ongoing inventory of wild-caught caterpillars spanning a variety of species within the family Sphingidae (Lepidoptera: Sphingidae). Our study provides a concise description of each new species using morphology, life history, molecular data and photographic documentation. In addition to the new species, the authors provide a re-description of the genus and a revised key to the species of *Metaplagia*. 
New information

The following five new species of *Metaplagia* are described: *Metaplagia leahdennisae* Fleming & Wood sp. n., *Metaplagia lindarobinsonae* Fleming & Wood sp. n., *Metaplagia paulinesaribasae* Fleming & Wood sp. n., *Metaplagia robinsherwoodae* Fleming & Wood sp. n. and *Metaplagia svetlanakozikae* Fleming & Wood sp. n.

The following is proposed by Fleming & Wood as new combination of *Plagiomima* Brauer & Bergenstamm, 1891: *Plagiomima latifrons* (Reinhard, 1956) comb. n.

Keywords
tropical rain forest, tropical dry forest, cloud forest, parasitoid flies, host-specificity, caterpillars, ACG, Dexiinae, Voriini

Introduction

The tribe Voriini is distributed globally; the vast tachinid fauna of the Neotropical Region and the huge number of genera have proven to be one of the most significant hurdles to understanding the tribal boundaries surrounding the Voriini. Most attempts to understand the synapomorphies or of the tribe have, rather than answered questions, led researchers to even more questions as to what the voriines truly are. Presently, the tribe possesses several diagnostic features which the authors consider as typical to the tribe: conical head profile (longer at level of pedicel than at vibrissa); proclinate, divergent and well-developed ocellar setae; frons wide; proclinate and reclinate orbital setae present in both sexes; facial ridge bare; prosternum bare; anepimeral seta absent or poorly developed appearing hair-like; infrasquamal setae present; apical scutellar setae strong and decussate; dm-m crossvein oblique, making posterior section of M₄ subequal to anterior section; R₄+₅ setulose at least to crossvein r-m and sometimes beyond; middorsal depression of ST1+2 reaching posterior margin; and aedeagus elongate and frequently ribbon-like (Tschorsnig 1985, Cortés and González 1989). Voriini lay flattened membranous incubated eggs directly on the cuticle of the host (Herting 1956, Guimarães 1977). Unfortunately, some of these diagnostic features can be observed across several other taxa within the Dexiinae and, as such, our recognition of the tribe can be seen as a combination of these features used to exclude other genera and define the Voriini; much variation exists within the catch-all tribe and the "gestalt" of the tribe is still somewhat nebulous. The Voriini are a problematic tribe and still the subject of much debate. Recent work has suggested that the Voriini are a vast unifying polyphyletic clade encompassing much of the Dexiinae (Stireman et al. 2019), only further emphasizing the catch-all nature of the tribe; this evidence, however, is still the subject of discussion.

The monotypic genus *Metaplagia* Coquillett, 1895 (Dexiinae: Voriini) was initially erected for the type species *Metaplagia occidentalis* Coquillett, 1895 (Coquillett 1895). Coquillet based the new species on a single male specimen he collected in San Diego Co.
California. The genus was previously known exclusively from the Nearctic; however, the data we present herein suggests the genus reaches into the Neotropics. A significant obstacle to revising a genus like *Metaplagia* is that the interspecific morphological differences are often subtle and, in many cases, variable. However, despite their morphological similarities, when examined at a genetic level, they display a great deal of interspecific variation, allowing the individual species to be further discriminated.

Our goal is to systematically revise and analyze the known members of the New World tachinid genus *Metaplagia* Coquillett and add to the existing taxa five new species from Area de Conservación Guanacaste (ACG). Our species concepts are based on differences in morphology, life history and by comparison of COI (coxI or cytochrome c oxidase I) gene sequences. We also provide a key to the species of *Metaplagia* inclusive of the Nearctic and Mesoamerican Regions. This paper is part of a broader effort to name and catalog all of the tachinid species collected from the ACG inventory, an effort which has already presented new information within the tribe Voriini (Fleming et al. 2017, Fleming et al. 2019). This series of taxonomic papers will represent a foundation for later, detailed ecological and behavioral accounts and studies, extending across ACG ecological groups, whole ecosystems and taxonomic assemblages much larger than a genus. All new information described here derives from the ongoing inventory of the tri-trophic relationships between caterpillars, their food plants and their parasitoids within the dry, rain and cloud forests of the terrestrial portion of ACG (Janzen et al. 2009, Janzen et al. 2011, Janzen and Hallwachs 2011, Janzen et al. 2020). This inventory started in 1978 and has yielded an unprecedented amount of invaluable ecological information on the tri-trophic relationships between parasitoids, hosts and associated food plants.

**Materials and methods**

**Project aims and rearing intensity**

All reared specimens were obtained from host caterpillars collected in ACG (Janzen and Hallwachs 2016). ACG's 125,000+ terrestrial hectares span the Provinces of Alajuela and Guanacaste, along the dry forested northwestern coast of Costa Rica and inland to the Caribbean lowland rain forest. ACG comprises several different biomes and intergrades, ranging from sea level up to 2,000 m. The tachinid rearing methods are described at [http://janzen.bio.upenn.edu/caterpillars/methodology/how/parasitoid_husbandry.htm](http://janzen.bio.upenn.edu/caterpillars/methodology/how/parasitoid_husbandry.htm). Since its inception, this inventory has reared over 750,000 wild-caught ACG caterpillars. Any frequencies of parasitization reported here need to be considered against this background inventory. Comparative details of the parasitization ecology of these flies will be treated separately in later papers, in the context of the study of all parasitization rates of tachinids on ACG caterpillars, once the overall alpha taxonomy of ACG caterpillar-attacking tachinids is more complete than at present.
Voucher specimen management

The management of voucher specimens has been detailed in previous papers in this series (Fleming et al. 2014). In brief, all caterpillars reared from the ACG efforts receive a unique voucher code in the format yy–SRNP–xxxxx. Any parasitoid emerging from a caterpillar receives the same voucher code as a record of the rearing event. If and when the parasitoid is later dealt with individually, it receives a second voucher code unique to it, in the format DHJPARxxxxxx. These voucher codes, assigned to both host and parasitoids, may be used to obtain the individual rearing record at http://janzen.bio.upenn.edu/caterpillars/database.lasso.

To date, all DHJPARxxxxxx-coded tachinids have had one leg removed for DNA barcoding at the Biodiversity Institute of Ontario (BIO) in Guelph, ON, Canada. All successful barcodes and collateral data are first deposited in the Barcode of Life Data System (BOLD, www.boldsystems.org) (Ratnasingham and Hebert 2007) and later migrated to GenBank. Each barcoded specimen is also assigned unique accession codes from both the Barcode of Life Data System (BOLD) and GenBank, respectively.

Inventoried Tachinidae were collected under Costa Rican government research permits issued to DHJ and exported from Costa Rica to Philadelphia, en route to their final depository in the Canadian National Insect collection in Ottawa, Canada (CNC). Tachinid identifications for the inventory were done by DHJ in coordination with: a) visual inspection by AJF and DMW, b) DNA barcode sequence examination by MAS and DHJ and c) correlation with host caterpillar identifications by DHJ and WH through the inventory itself. Dates of collection, cited for each ACG specimen, are the dates of eclosion of the fly, not the date of capture of the caterpillar since the fly eclosion date is much more representative of the time when that fly species is on the wing than is the time of capture of the host caterpillar. The collector listed on the label is the parataxonomist who found the caterpillar, rather than the person who retrieved the newly-eclosed fly from its rearing container. The holotypes and paratypes of the species newly-described herein are all deposited at CNC.

Descriptions and imaging

Species accounts and descriptions are deliberately brief and concise, complemented by a series of color photos of every species, used to illustrate the morphological differences amongst them. The morphological terminology used follows Cumming and Wood (2017). All dissections and photography were carried out following the methods detailed in Fleming et al. (2014). If only one male were available, it was designated as the holotype and not subjected to dissection.

Interim names of undescribed host species

Names of undescribed host species follow a standardized, interim naming system used for taxonomic units considered as distinct species and identified by DNA barcodes. The interim names are given in the format "Manduca sextaDHJ02" or "Manduca sextaDHJ03",...
where the "species epithet" is either composed of the name of the taxonomist who identified the species and a number or the name of a species-group, followed by a code. This prevents confusion with already-described species, while maintaining traceability of each undescribed species within the ACG project.

DNA barcoding

We generated DNA extracts from single legs using a glass fibre protocol (Ivanova et al. 2006), using the standard DNA barcode region (5' cytochrome c oxidase I (COI) gene) for all specimens of ACG *Metaplagia*. The DNA barcodes (658 bp near the 5' terminus of the COI gene) were amplified using general insect primers, using standard protocols for both production and quality control (Smith et al. 2006, Smith et al. 2007, Smith et al. 2008, Smith et al. 2009, Smith 2012). DNA sequences, trace files and accessions were deposited in the Barcode of Life Data System (BOLD) (Ratnasingham and Hebert 2007). Metadata (including GenBank accession codes) associated with each sequence can be consulted on BOLD by using the persistent DOI (https://doi.org/10.5883/DS-ASMETAPL).

The phylogeny (Fig. 1) was created using the Maximum Likelihood method, based on the Tamura 3-parameter model (Tamura 1992) created using holo- and paratype DNA barcode sequences. Aligned with each tip of the tree (species name|DHJPARxxxxxxxx accession) is a pictorial representation of the DNA barcode of that specimen and the lateral image of the holotype for that species. The best nucleotide substitution model and the phylogeny itself were created using MEGA X (Kumar et al. 2018) and the figure created using the R (R Core Team 2019) package ggtree (Yu et al. 2017).

Taxon treatments

*Metaplagia* Coquillett, 1895

**Nomenclature**

*Metaplagia* Coquillett, 1895: 102 [also 1895: 97]. Type species: *Metaplagia occidentalis* Coquillett, 1895, by original designation.

*Metavoria* Townsend, 1915: 101. Type species: *Metavoria orientalis* Townsend, 1915, by original designation. Synonymy proposed by Wood 1987: 1250, and further clarified in O’Hara and Wood 1998: 755.

*Agathomyia* Reinhard, 1959: 228 (preocc. by Verrall, 1901). Type species: *Agathomyia cordata* Reinhard, 1959, by original designation. Synonymy proposed by Wood 1987: 1250, and further clarified in O’Hara and Wood 1998: 763.

*Anzamyia* Reinhard, 1960: 103. (nomen novum for *Agathomyia*, 1959 Reinhard).

**Other species included in *Metaplagia* Coquillett**

*Metaplagia brevicornis* Brooks, 1945: 81. Holotype male (CNC), by original designation. Type locality: Canada, Manitoba, Teulon.

*Agathomyia cordata* Reinhard, 1959: 229. Holotype female (UCDC) (1 female paratype in CNC), by original designation. Type locality: USA, California, Riverside County, Anza.

*Metavoria facialis* Reinhard, 1956: 123. Holotype female (CNC). Type locality: USA, Utah, Fruitland.

*Metaplagia occidentalis* Coquillett, 1895: 103. Holotype male (USNM, Type No. USNM ENT01519725), by original designation. Type locality: USA, California, San Diego County.

*Metavoria orientalis* Townsend, 1915: 101. Holotype female (USNM, Type No. USNME NT01519726), by original designation. Type locality: USA, Virginia, Arlington.
Type species

*Metaplagia occidentalis* Coquillett, 1895

Description

Male, **head**: frontal vitta wide, 1/3-1/6th width of front-orbital plate; with 2–3 proclinate orbital setae and 1–2 reclinate orbital setae; ocellar setae proclinate slightly divergent; eye bare, not descending beyond the level of the vibrissa; fronto-orbital plate coloration ranging from shining silver to gold; fronto-orbital plate with short black setulae interspersed amongst frontal setae; fronto-orbital setae not extending below lower margin of pedicel, with fronto-orbital setulae sometimes extending below lower margin of pedicel; pedicel orange, with a black-dark brown post pedicel; arista bare and subequal to slightly shorter than postpedicel, distinctly-thickened on basal 1/2-2/3, ranging from dark orange to dark brown-black; lower margin of face almost level with vibrissa, not visible in profile; facial ridge bare, but with setulae along parafacial sometimes so close to facial ridge as to be confused with facial ridge setulae; palps either straight or with a slight club at apex, sparsely setulose. **Thorax**: tomentosity ranging from pale beige-gray to dark grey or silver over a black ground color; thorax black ground color tomentum of thorax ranging from pale brassy to silver grey; prosternum bare; 3–4 postpronotal setae arranged in a straight line; supra-alar setae 1–2:3; intra-alar setae 2–3:3; dorsocentral setae 3:3–4; acrostichal setae 3:3; katepisternum with 3 setae. Scutellum black ground color, with tomentum ranging from gray to pale brassy; with five pairs marginal setae; apical scutellar setae 1/2–1/3 as long as subapical scutellars, sub-erect, slightly above marginal plane; basal scutellar subequal in length to subapical setae; subapical setae straight, ranging from convergent to divergent. Legs: dark reddish-brown to black ground color; tarsal claws and pulvilli ranging from shorter than to longer than last tarsomere. Wings: slightly longer than abdomen; translucent slightly hyaline; R₁ and R₄+5 can be setulose, setulae of R₄+5 ranging from node to crossvein r-m or beyond. **Abdomen**: ground color black, pale silver tomentum in varying degrees on T₃–T₅, ST₁+₂ typically glabrous; middorsal depression on ST₁+₂ reaching to hind margin of tergite; median marginal setae present on T₃ and complete rows on T₄ and T₅; median discal setae absent on all tergites; sex patch absent.

**Terminalia**: posterior margin of sternite 5 with a deeply excavated and wide U-shaped (sometimes sculptured) median cleft; lateral lobes of sternite apically rounded, often with setae along caudal margin; basal section 1/5 the length of apical lobes. Epandrium often with 3–4 long, strong setae along anal edge. Cerci, in posterior view, medially separated, but parallel and often touching so as to appear fused, with a few short setae on basal half. In lateral view, bowed and sharply tapered apically. Surstylus well-developed, stout basally in lateral view, like a stout broadly rounded triangle terminating in a small knob, appearing hooked or slightly beaked apically; in posterior view, basally enlarged and apically straight.
Female as in male, except in the following aspects: head: tomentum of fronto-orbital plate and parafacial can sometimes differ from that of the conspecific male; fronto-orbital plate and parafacial up to 0.5x wider than in males.

Diagnosis

_Metaplagia_ can be distinguished by the following combination of traits: head distinctly conical; males with upper frontal setae reclinate; proclinate orbital setae in both sexes; frontal setae descending below level of pedicel; both sexes with well-developed lateral vertical setae; eye bare; parafacial setulose, but not with strong stout setae, only hair-like setulae; genal dilation very slightly developed; prementum shorter than height of head with an enlarged labellum; prosternum bare; three postsutural supra-alar setae, the anteriormost reduced and much weaker than first postsutural dorsocentral seta; scutellum with four pairs of marginal setae and one pair of erect to semi-erect apical setae; one or two pairs of sub-erect discal setae on scutellum, in line with subapical setae; vein M₁ ending separately in wing margin; anepimeral seta short, not extending beyond edge of lower calypter; wing vein R₄₊₅ setulose.

Distribution

From Manitoba, Canada east to Newfoundland and south to Costa Rica.

Ecology

Within the ACG inventory, _Metaplagia_ has only been reared from the Lepidoptera family Sphingidae: Lepidoptera throughout the diverse ecosystems of the research area.

Taxon discussion

Our present revision of _Metaplagia_ increases the range of the genus, taking it from being a Nearctic endemic genus to a complete New World distribution, inclusive of both the Nearctic and Neotropical Regions.

Both _Plagiomima_ Brauer & Bergenstamm, 1891 and _Metaplagia_ are extremely similar genera; however, these can be very easily distinguished by the conformation of their mouthparts (Wood and Zumbado 2010). After careful examination of the holotype of _Metaplagia latifrons_ Reinhard and based on the generic concepts and diagnostic features of both _Metaplagia_ and _Plagiomima_, the authors hereby propose that species _Metaplagia latifrons_ Reinhard, 1956 be transferred into the genus _Plagiomima_, as _Plagiomima latifrons_ (Reinhard) comb. n. We base this taxonomic action on the similarities presented between the slender elongated mouthparts and the slender apically pointed surstyli present in _Metaplagia latifrons_, both diagnostic features observed in the genus _Plagiomima_, yet absent from the genus _Metaplagia_.

---

Description

Male (Fig. 2), head (Fig. 2c, d): fronto-orbital plate wide, coloration silver with gold tomentum over uppermost 50%, appearing as pale brassy gold along upper 50% of occipital margin of eye; vitta wide, 1/3 width of fronto-orbital plate; ocellar setae lateradlocinate with a slight proclinate skew; with 3 procline orbital setae (middle procline orbital seta most often shorter and thinner than the other two) and 1 reclinate orbital seta fronto-orbital plate with short black setulae interspersed amongst frontal setae; fronto-orbital setulae extending below lower margin of the pedicel, well into the angle of parafacial; parafacial wholly silver tomentose; palps either slightly spathulate at tips, apically acutely inwardly curved, sparsely setulose along outer margins, inner margin appearing bare; arista dark brown-black. Thorax (Fig. 2a, b): black ground color with pale grey to brassy tomentum; 4 postpronotal setae; supra-alar setae 2:3; intra-alar setae 3:3; dorsocentral setae 3:3; acrostichal setae 3:3; katepisternum with 3 setae. Infrasquama setae present. Scutellum black ground color, with tomentum concolorous with thorax; with five pairs marginal setae; apical scutellar setae 1/2 as long as subapical scutellars, sub-erect, arising above plane of marginal setae; basal scutellar subequal in length to subapical setae; subapical setae convergent, lateral scutellar setae can be convergent or strongly divergent. Legs: black ground color; mid tibia with 2–3 strong anteroventral setae; tarsal claws and pulvilli shorter than last tarsomere. Wings: R₁ bare, R₄₊₅ setulose from node to crossvein r-m. Abdomen (Fig. 2a, b): ground color black; ST₁+2 glabrous black, pale silver tomentum, occupying anterior 60% of T₃–T₅; tomentum not extending to ventral surface of abdomen; median marginal setae present on T₃ and complete rows on T₄ and T₅.

Terminalia (Fig. 3): posterior margin of sternite 5 with a deeply excavated U-shaped median cleft (Fig. 3d); lateral lobes of sternite apically rounded, with a vestiture of short setae along disc, 3x as long along caudal margin; basal section 1/5 the length of apical lobes. Cerci, in posterior view, medially separated and parallel, not often touching medially, with a few short setae on basal half (Fig. 3a). In lateral view, bowed and sharply tapered apically (Fig. 3b). Surstylus well-developed, stout basally in lateral view, like a broadly rounded triangle, appearing hooked or slightly beaked apically (Fig. 3b, c); in posterior view, basally enlarged and apically straight.

Female (Fig. 4) as in male, except in the following aspects: head (Fig. 4c, d): frontal vitta 1/2 width of fronto-orbital plate overall brown with a light gold sheen of tomentum; overall head of females 1/5 wider than that of males; setulae interspersed amongst frontal setae more dense than in males; 3–4 rows of parafacial setulae. Legs (Fig. 4a, b): mid-tibia with 3–4 irregularly-sized strong anteroventral setae.

Diagnosis

Metaplagia leahdennisae sp. n. can be distinguished from all other Metaplagia by the following combination of traits: fronto-orbital plate at least 50% gold, with a silver parafacial and setulae on vein R₄₊₅ not extending beyond crossvein r-m. Metaplagia leahdennisae sp. n. can be separated from Metaplagia occidentalis by the presence of
gold on the fronto-orbital plate. *Metaplagia leahdennisae* sp. n. is clearly distinguished by its COI sequence clustered within the Barcode Identification Number (BIN) **BOLD:AAE2876**.

---

**Etymology**

*Metaplagia leahdennisae* sp. n. is named in honor of Leah Dennis for her many years of coordinating and administrating a plethora of problems and events in the Academic Office of the Department of Biology, University of Pennsylvania, Philadelphia, Pennsylvania.
Distribution

Costa Rica, ACG, Guanacaste Province, 5–275 m elevation.

Ecology

*Metaplagia leahdennisae* sp. n. has been reared eight times from one species of Lepidoptera in the family Sphingidae: *Agrius cingulata* (Fabricius, 1775) in dry forest.

Description

Male (Fig. 5), head (Fig. 5c, d): fronto-orbital plate wide, coloration silver to pale grey; vitta wide, 1/3 width of fronto-orbital plate occellar setae laterolocninate with a slight proclinate skew; with 3–4 procline orbital setae (middle procline orbital setae most often shorter and thinner than the other two) and 1 reclinate orbital seta fronto-orbital plate with short black setulae interspersed amongst frontal setae; fronto-orbital setulae extending below lower margin of pedicel, well into angle of parafacial; parafacial wholly silver tomentose with a distinct row of parafacial setae along inner margin of parafacial approaching facial ridge, seemingly continuous with fronto-orbital setulae; palps either slightly spatulate at tips, apically acutely inwardly curved, extremely sparsely setulose along inner margin, remainder appearing bare; arista dark brown-black. Thorax (Fig. 5a, b): black ground color with pale grey tomentum; 3–4 postpronotal setae; supra-alar setae 2.3; infra-alar setae 3.3; dorsocentral setae 3.3; acrostichal setae 3.3; katepisternum with 3 setae. Infrasquamous setae present. Scutellum black ground color, with tomentum concolorous with thorax; with five pairs marginal setae; apical scutellar setae 1/2 as long as subapical scutellars, sub-erect,
arising above plane of marginal setae; basal scutellar subequal in length to subapical setae; subapical setae convergent, lateral scutellar setae can be convergent or strongly divergent. Legs: black ground color; mid tibia with 2–3 strong anteroventral setae; tarsal claws and pulvilli shorter than last tarsomere. Wings: R₁ bare, R₄₊₅ setulose from node up to, but not beyond, crossvein r-m. **Abdomen** (Fig. 5a, b): ground color black; ST1+2 glabrous black, pale silver tomentum occupying anterior 50% of T3–T5; tomentum not extending to ventral surface of abdomen; median marginal setae present on T3, and complete rows on T4 and T5.

**Figure 5.**

*Metaplagia lindarobinsonae* sp. n. habitus images a–d: male, holotype n. DHJPAR0059091

|   |   |
|---|---|
| a | b |
| c | d |

**Terminalia** (Fig. 6): posterior margin of sternite 5 with a deep and narrow excavated U-shaped median cleft (Fig. 6d); lateral lobes of sternite apically rounded, with a vestiture of short setae along disc, 3x as long along caudal margin; basal section 1/3 the length of apical lobes. Cerci, in posterior view, medially separated and parallel not touching
medially, with a few short setae on basal half (Fig. 6a); in lateral view, bowed and sharply tapered to a point apically (Fig. 6b, c). Surstylus well-developed, stout basally in lateral view, rounded basally and appearing hooked or slightly beaked apically; in posterior view, basally enlarged and apically straight.

Female (Fig. 7) as in male, except in the following aspects: head (Fig. 7c, d): fronto-orbital just under 1/2 of head width, vitta 1/3 width of fronto-orbital plate; overall head of females 1/5 wider than that of males; legs (Fig. 7b): mid-tibia with 3–4 irregularly-sized strong anteroventral setae.
Metaplagia lindarobinsonae sp. n. can be distinguished from all other Metaplagia by the following combination of traits: frontal vitta indistinct around ocellar triangle, infrasquamal setae present, fronto-orbital plate at pale gray or silver, with a silver parafacial and setulae on vein R_{4+5} not extending beyond crossvein r-m, surstylus sharp at tip. Metaplagia lindarobinsonae sp. n. can be separated from Metaplagia occidentalis by the presence of infrasquamal setae and from Metaplagia svetlanakozikae sp. n. by the presence of a distinct row of setulae along the facial ridge. Metaplagia lindarobinsonae sp. n. is clearly distinguished by its COI sequence clustered within the Barcode Identification Number (BIN) BOLD:AAD5563.
Etymology

*Metaplagia lindarobinsonae* sp. n. is named in honor of Linda Robinson for her many years of coordinating and administrating a plethora of problems and events for the undergraduate biology teaching laboratories of the Department of Biology, University of Pennsylvania, Philadelphia, Pennsylvania.

Distribution

Costa Rica, ACG, Guanacaste Province, 85–300 m elevation.

Ecology

*Metaplagia lindarobinsonae* sp. n. has been reared 17 times from two species of Lepidoptera in the family Sphingidae: *Manduca sexta* (Linnaeus, 1763), *Manduca sexta* DHJ02 and *Manduca sexta* DHJ03, in dry forest.

Description

Male (Fig. 8), **head** (Fig. 8c, d): fronto-orbital plate wide, gold tomentum over its entirety; vitta wide, 1/5 width of fronto-orbital plate; ocellar setae laterooclinate with a slight procline skew; with 2 procline orbital setae and 1 reclinate orbital seta fronto-orbital plate with short black setulae interspersed amongst frontal setae; fronto-orbital setulae extending below lower margin of the pedicel, well into angle of parafacial; parafacial wholly gold tomentose; palps either slightly spathulate at tips, apically acutely inwardly curved, 3–4 setulae along lower margin, inner margin appearing bare; arista light brown-dark orange, distinctly lighter color than postpedicel. **Thorax** (Fig. 8a, b): black ground color with pale brassy tomentum; 4 postpronotal setae; supra-alar
setae 2:3; intra-alar setae 3:3; dorsocentral setae 3:3; acrostichal setae 3:3; katepisternum with 3 setae. Infrasquamal setae present. Scutellum black ground color, with tomentum concolorous with thorax; with five pairs marginal setae; apical scutellar setae 1/2 as long as subapical scutellars, sub-erect, arising above plane of marginal setae; basal scutellar subequal in length to subapical setae; subapical setae convergent, lateral scutellar setae can be convergent or strongly divergent; 2 pairs of scutellar discal setae set wider apart than subapical setae. Legs: black ground color; mid tibia with 2–3 strong anteroventral setae; tarsal claws and pulvilli shorter than last tarsomere. Wings: R₁ bare, R₄+₅ setulose from node to crossvein r-m. Abdomen (Fig. 8a, b): ground color black; ST1+2 glabrous black, silver-pale brassy tomentum occupying anterior 90% of T3–T5; tomentum thin to absent along ventral surface of abdomen; median marginal setae present on T3 and complete rows on T4 and T5.

Terminalia: holotype male not dissected.

Female: unknown at this time.

**Diagnosis**

*Metaplagia paulinesaribasae* sp. n. can be easily distinguished from all other *Metaplagia* by the following combination of traits: both fronto-orbital and parafacial gold and setulae on vein R_{4+5} not extending beyond crossvein r-m. It is distinguishable from all other congeners by the presence of an entirely gold fronto-orbital plate and parafacial. *Metaplagia paulinesaribasae* sp. n. is clearly distinguished by its COI sequence clustered within the Barcode Identification Number (BIN) [BOLD:AAX4230](http://www.boldsystems.org).

**Etymology**

*Metaplagia paulinesaribasae* sp. n. is named in honor of Pauline Saribas for her many years of coordinating and administrating a plethora of problems and events in the Academic Office of the Department of Biology, University of Pennsylvania, Philadelphia, Pennsylvania.

**Distribution**

Costa Rica, ACG, Guanacaste Province, 280 m elevation.

**Ecology**

*Metaplagia paulinesaribasae* sp. n. has been reared once from one species of Lepidoptera in the family Sphingidae: *Manduca lefeburii* (Guérin-Méneville, 1844), in dry forest.

Description

Male (Fig. 9), head (Fig. 9c, d): fronto-orbital plate wide, coloration silver with gold tomentum over uppermost 50%, appearing as pale brassy gold along upper 25% of occipital margin of eye; frontal vitta wide, 1/5 width of fronto-orbital plate almost entirely covered in gold tomentum; ocellar setae strongly proclinate slightly divergent; with 3 proclinate orbital setae (middle proclinate orbital seta most often almost hair-like reduced) and 1 reclinate orbital seta fronto-orbital plate with only a sparse few short
black setulae interspersed amongst frontal setae; sparse fronto-orbital setulae extending below lower margin of the pedicel (very few), these not intermingled with those in angle of parafacial; parafacial wholly silver tomentose with a single row of parafacial setulae mid-way along parafacial near facial ridge; palps slightly spatulate at tips almost oar-shaped, apically acutely inwardly curved, setulose along outer margins, inner margin appearing bare; arista dark brown-black. **Thorax** (Fig. 9a, b): black ground color with pale grey with a slightly brassy tinged tomentum, laterally this color transitions to a darkened grey tomentum; 4–5 postpronotal setae; supra-alar setae 2:3; intra-alar setae 3:3; dorsocentral setae 3:3-4; acrostichal setae 3:3; katepisternum with 3 setae. Infrasquama setae absent. Scutellum black ground color, with tomentum concolorous with disc grey thorax; with four pairs marginal setae; apical scutellar setae absent; basal scutellar 2/3 length of subapical setae; subapical setae convergent, lateral scutellar setae strongly divergent. Legs: black ground color; mid tibia with 2–3 strong anteroventral setae; tarsal claws and pulvilli shorter than last tarsomere. Wings: R₁ bare, R₄+₅ setulose from node slightly beyond crossvein r-m. **Abdomen** (Fig. 9a, b): ground color black; ST₁+₂ glabrous black, pale silver tomentum occupying anterior 60% of T₃–T₅; tomentum extending to ventral surface of abdomen on T₄ and T₅; median marginal setae present on T₃ and complete rows on T₄ and T₅. **Terminalia** (Fig. 10): posterior margin of sternite 5 with a deeply excavated and sculptured U-shaped median cleft (Fig. 10d); lateral lobes of sternite apically rounded, widened at mid-point and tapering again towards base, with a vestiture of short setae along disc, 3x as long along caudal margin; basal section slightly less than 1/5 the length of apical lobes. Cerci, in posterior view, medially separated, with a few short setae along entire length, setae lengthening posteriorly towards anal operculum (Fig. 10a). In lateral view, bowed and sharply tapered apically (Fig. 10b, c). Surstylus well-developed, stout basally in lateral view, like a broadly rounded triangle, appearing like a rounded ellipsoid leaf shape; in posterior view, basally enlarged and apically straight. Female (Fig. 11) as in male, except in the following aspects: **head** (Fig. 11c, d): fronto-orbital just under 1/2 of head width, vitta 1/4 width of fronto-orbital plate; ocellar setae laterooclinate; post-pedicel slightly orange along basal 1/5. Legs (Fig. 11b): mid-tibia with 3–4 irregularly-sized strong anteroventral setae.

**Diagnosis**

*Metaplagia robinsherwoodae* sp. n. can be distinguished from all other *Metaplagia* by the following combination of traits: fronto-orbital plate at least 75% gold, with a silver parafacial and setulae on vein R₄+₅ extending well beyond crossvein r-m. *Metaplagia robinsherwoodae* sp. n. can be separated from *M. leahdennisae* and *M. paulinesaribasae* by the presence of setulae on R₄+₅ extending well beyond crossvein r-m and it is separated from *M. facialis* and *M. cordata* by the presence of gold on its fronto-orbital plate. *Metaplagia robinsherwoodae* sp. n. is clearly distinguished by its COI sequence clustered within the Barcode Identification Number (BIN) BOLD:AAB3286.
Etymology

*Metaplagia robinsherwoodae* sp. n. is named in honor of Robin Sherwood for her many years of coordinating and administrating a plethora of problems and events in the Academic Office of the Department of Biology, University of Pennsylvania, Philadelphia, Pennsylvania.

Distribution

Costa Rica, ACG, Guanacaste Province, 250–300 m elevation.

Description

Male (Fig. 12), head (Fig. 12c, d): fronto-orbital plate wide, coloration silver with pale brassy tomentum over uppermost 10%, appearing as pale brassy gold along upper 25% of occipital margin of eye; vitta wide, 1/3 width of fronto-orbital plate; ocellar setae laterooclinate with a slight procline skew; with 3 procline orbital setae (middle procline orbital seta shorter and thinner than the other two) and 1 reclinate (often outwardly laterooclinate) orbital seta; fronto-orbital plate with a sparse vestiture of short black setulae interspersed amongst frontal setae; fronto-orbital setulae not extending below pedicel; parafacial wholly silver tomentose, upper 1/3 of parafacial with small grouping of short black setulae in line with frontal setae, but separated from fronto-orbital plate; palps very slightly spatulate at tips, apically acutely inwardly curved, sparsely setulose along ventral surface, inner and upper surfaces appearing bare; arista dark brown-black. Thorax (Fig. 12a, b): black ground color with pale grey tomentum, brassy tones can occur under certain light; 4 postpronotal setae, anteriormost seta thin and weak almost hair-like; supra-alar setae 2:3; intra-alar setae 3:3; dorsocentral setae 3:3; acrostichal setae 3:3; katepisternum with 3 setae. Infrasquamal setae present. Scutellum black ground color, with tomentum concolorous with thorax; with five pairs marginal setae; apical scutellar setae 1/2 as long as subapical scutellars, sub-erect, arising above plane of marginal setae; basal scutellar 2/3 length of subapical setae; subapical setae convergent, lateral scutellar setae can be convergent or strongly divergent. Legs: black ground color; mid tibia with 2–3 strong anteroventral setae; tarsal claws and pulvilli as long as last tarsomere. Wings: R₁ bare, R₄+₅ setulose from node to crossvein r-m. Abdomen (Fig. 12a, b): ground color black; ST₁+₂ glabrous black, pale silver tomentum occupying anterior 75% of T3 and T4, T5 pale brassy-grey tomentose over entirety; tomentum extending to ventral surface of abdomen, but not completely; median marginal setae present on T3 and complete rows on T4 and T5.

Terminalia (Fig. 13): posterior margin of sternite 5 with a deeply excavated U-shaped median cleft (Fig. 13d); lateral lobes of sternite apically rounded, with a vestiture of short setae along disc, 2x as long along caudal margin; basal section 1/2 the length of apical lobes. Cerci, in posterior view, sharply pointed and slightly medially separated and parallel, almost touching medially, with a few short setae on basal half (Fig. 13a). In lateral view, curved and sharply tapered apically (Fig. 13b). Surstylus well-developed, stout basally in lateral view, broadly rounded; in posterior view, basally enlarged and apically straight.

Female (Fig. 14) as in male, except in the following aspects: head (Fig. 14c, d): fronto-orbital wider than males, just over 1/2 of head width entirely bright silver tomentose, frontal vitta 2/5 width of fronto-orbital plate; overall head of females 1.5x wider than that of males; legs (Fig. 14b): mid-tibia with 3–4 irregularly-sized strong anteroventral setae.
Diagnosis

Metaplagia svetlanakozikae sp. n. can be distinguished from all other Metaplagia by the following combination of traits: frontal vitta indistinct around ocellar triangle, infrasquamal setae present, fronto-orbital plate at pale gray or silver, with a silver parafacial and setulae on vein R_{4+5} not extending beyond crossvein r-m, surstylus rounded at tip. Metaplagia svetlanakozikae sp. n. can be separated from Metaplagia occidentalis by the presence of infrasquamal setae and from Metaplagia lindarobinsonae sp. n. by the presence of a small circular formation of setulae on the parafacial and not distinct row of setulae along the facial ridge. Metaplagia svetlanakozikae sp. n. is clearly distinguished by its COI sequence clustered within the Barcode Identification Number (BIN) BOLD:AAD5456.
Etymology

*Metaplagia svetlanakozikae* sp. n. is named in honor of Svetlana Kozik for her years of coordinating and administrating a plethora of problems and events for the undergraduate biology teaching laboratories of the Department of Biology, University of Pennsylvania, Philadelphia, Pennsylvania.

Distribution

Costa Rica, ACG, Guanacaste Province, 10–280 m elevation.
Ecology

*Metaplagia svetlanakozikae* sp. n. has been reared seven times from one species of Lepidoptera in the family Sphingidae: *Agrius cingulata*, in dry forest.

**Identification keys**

| Key to the *Metaplagia* of North and Mesoamerica |
|-----------------------------------------------|
| 1  | Setulae present on wing vein R_{4+5} not extending beyond crossvein r-m | 2 |
|    | – Setulae present on wing vein R_{4+5} extending beyond crossvein r-m | 8 |
| 2  | Fronto-orbital plate and parafacial entirely and uniformly gold | *paulinesaribasae* sp. n. |
|    | – Fronto-orbital plate at most with some gold present and parafacial not gold | 3 |
| 3  | Fronto-orbital plate bearing some gold | *leahdennisae* sp. n. |
|    | – Fronto-orbital plate pale grey or silver (can include pale brassy) distinctly not gold | 4 |
| 4  | Infrasquamal setae absent | *occidentalis* Coquillett, 1895 |
|    | – Infrasquamal setae present | 5 |
| 5  | Frontal vitta indistinct around ocellar triangle, not reaching occiput | 6 |
|    | – Frontal vitta wide and prominent extending around ocellar triangle to occiput | 7 |
| 6  | Parafacial setulae descending along parafacial in a row near facial ridge; surstylus sharp at tip | *lindarobinsonae* sp. n. |
|    | – Parafacial setulae present as a small circular grouping along upper 1/3 of parafacial, not in a row near facial ridge; surstylus rounded at tip | *svetlanakozikae* sp. n. |
| 7  | Postpedicel just over 3 times as long as pedicel; claws and pulvilli shorter than last tarsomere | *brevicornis* Brooks, 1945 |
|    | – Postpedicel 2 times as long as pedicel; claws and pulvilli longer than last tarsomere | *orientalis* Townsend, 1915 |
|   | Description                                      | Reference                |
|---|--------------------------------------------------|--------------------------|
| 8 | Fronto-orbital plate gold on at least upper two thirds | *robinsherwoodae* sp. n. |
|   | Fronto-orbital plate entirely silver              | 9                        |
| 9 | Wing vein R₁ bare throughout                      | *facialis* Reinhard, 1956 |
|   | Wing vein R₁ setulose throughout                  | *cordata* Reinhard, 1960 |

Acknowledgements

We gratefully acknowledge the unflagging support of the team of ACG parataxonomists (Janzan et al. 2009, Janzen & Hallwachs 2011) who found and reared the specimens used in this study and the team of biodiversity managers who protect and manage the ACG forests that host these tachinids and their caterpillar hosts. The study has been supported by U.S. National Science Foundation grants BSR 9024770 and DEB 9306296, 9400829, 9705072, 0072730, 0515699 and grants from the Wege Foundation, International Conservation Fund of Canada, Jessie B. Cox Charitable Trust, Blue Moon Fund, Guanacaste Dry Forest Conservation Fund, Area de Conservación Guanacaste, Peruvian Global and University of Pennsylvania (DHJ & WH) and in-kind support from INBio and the Museo Nacional de Costa Rica. This study has also been supported by the Government of Canada through its ongoing support of the Canadian National Collection, Genome Canada, the Biodiversity Institute of Ontario and the Ontario Genomics Institute (2008–0GI–ICI–03) (MAS) and by a Discovery Grant from Natural Sciences and Engineering Research Council of Canada (MAS). AJF and DMW would also like to extend a very special thank you Dr. Torsten Dikow (USNM), Dr. Nigel Wyatt (BMNH), Dr. David Grimaldi (AMNH) and his technician Courtney Richenbacher who provided invaluable information relative to types in their museums. Acknowledgements to Dr. James E. O’Hara and Shannon Mahony Henderson, for allowing us to make use of their indispensable literature library and World Tachinidae Database (MW & AJF).
