* The startup and shutdown cost of generating unit is assumed to be proportional to the capacity. For example, a 500-MW unit has a startup and shutdown cost of 500000 ¥.
Supplementary Table 4. Fuel cost and emission factor by power plant type.

| Plant type   | Fuel cost (¥/kWh) | Emission factor (kg/kWh) |
|--------------|-------------------|--------------------------|
| Coal         | 0.37              | 1.22945                  |
| Natural gas  | 0.65              | 0.3756                   |
Supplementary Note 1. Detailed description of Global Solar Energy Estimator (GSEE) model

According to the study by Pfenninger et al., the power output of PV modules depends on the in-plane irradiance $G$ and module temperature $T_{mod}$:

$$P_{PV} (G, T_{mod}) = \frac{P_{STC}^{PV}}{G_{STC}} \cdot \eta_{rel} (G', T')$$  \hspace{1cm} (1a)$$

where $P_{STC}^{PV}$ is the power output at standard test conditions (STC) with in-plane irradiance $G_{STC}$ of 1000W/m² and module temperature $T_{mod, STC}$ of 25 °C. The hourly instantaneous relative efficiency $\eta_{rel}$, depending on the instantaneous irradiance and temperature, is given by

$$\eta_{rel} (G', T') = 1 + k_1 \ln G' + k_2 (\ln G')^2 + T' [k_3 + k_4 \ln G' + k_5 (\ln G')^2] + k_6 T'^2$$  \hspace{1cm} (1b)$$

where $G' = \frac{G}{G_{STC}}$ and $T' = T_{mod} - T_{mod, STC}$ are normalized parameters to STC values. $k_1$-$k_6$ are coefficients determined by experimental data. $T_{mod}$ can be further calculated by the ambient temperature and irradiation $G$ as follows:

$$T_{mod} = T_{amb} + c_T G$$  \hspace{1cm} (1c)$$

where $c_T$ represents how much PV module is heated by irradiation $G$.

The in-plane irradiance $G$ includes the direct and diffuse plane irradiance ($G_{dir}$ and $G_{dif}$), which can be computed from the global direct and diffuse irradiance ($I_{dir}$ and $I_{dif}$) by

$$G_{dir} = \frac{I_{dir} \cdot \cos(\alpha)}{\cos(\frac{\pi}{2} - a_s)}$$  \hspace{1cm} (1d)$$

$$G_{dif} = I_{dif} \cdot \frac{1 + \cos(\Sigma)}{2} + a \cdot (I_{dir} + I_{dif}) \cdot \frac{1 - \cos(\Sigma)}{2}$$  \hspace{1cm} (1f)$$

where $\alpha$ is the plane incidence angle, calculated by (1g) with a fixed tilt angle. $a_s$ is the sun azimuth angle, $a$ is the surface albedo ($a=0.3$).

$$\alpha = \arccos \left( \sin(h) \cdot \cos(\Sigma) + \cos(h) \cdot \sin(\Sigma) + \cos(a_p - a_s) \right)$$  \hspace{1cm} (1g)$$

where $h$ is sun altitude, $a_p$ is panel azimuth, and $a_s$ is sun azimuth angle. $\Sigma$ is the plane tilt in degrees, calculated by

$$\Sigma = 1.3793 + lat \cdot (1.2011 + lat \cdot (-0.014404 + lat \cdot 0.000080509))$$  \hspace{1cm} (1h)$$

where $lat$ is the latitude in degrees. Considering that the plum rain-affected areas occur near latitude 30°N, we set the optimum tilt angle of the fixed-tilt system to 26.6 degrees, following the study by Chen et al. In the end, the system loss is set to the default value of 0.1.
Supplementary Note 2. Comparison of various pathways.

Based on the above optimization results, we further compare four pathways in offsetting the incremental CO₂ emissions caused by plum rain. First, we use the \( C_{\text{ES}} \), which is obtained in the first optimization, as a known quantity in the following optimization model to eliminate the influence of electric storage. Then, we also add the calculated \( \Delta E \) and PV reduction \( \Delta P_{\text{PV}} \) caused by plum rain in the following optimization model to measure the capacity required for each pathway.

The PV reduction \( \Delta P_{\text{PV}} \) can be calculated as

\[
\Delta P_{\text{PV}} = \sum_{l=1}^{n} \sum_{t, \in \Phi_t^l} P_{l}^{(2)}(t) - \sum_{l=1}^{n} \sum_{t, \in \Phi_t^l} P_{l}^{(1)}(t)
\]

where \( P_{l}^{(1)}(t) \) and \( P_{l}^{(2)}(t) \) are the actual output power of \( l \)-th PV generator in the affected region at the first and second optimization, respectively.

1) Coal power to natural gas power (C2N)

The objective function is revised as follows:

\[
\min_{\mathbf{X}'} C = \sum_{t, \in \Phi_t^l} \left[ c_l^{\text{TG}} P_t^{\text{TG}}(t) + c_l^{\text{IK}} Y_t(t) + c_l^{\text{DR}} Z_t(t) \right] + \phi_{\text{PV}} \sum_{l, \in \Phi_t^l} \sum_{t, \in \Phi_t^l} \left[ \rho_{l1}^{\text{PV}}(t) C_{l1}^{\text{PV}} - P_{l1}^{\text{PV}}(t) \right] + \phi_{\text{PV}} \sum_{l, \in \Phi_t^l} \sum_{t, \in \Phi_t^l} \left[ \rho_{l2}^{\text{PV}}(t) C_{l2}^{\text{PV}} - P_{l2}^{\text{PV}}(t) \right]
\]

\[
+ c_{\text{ES}}^{\text{PR}} + \phi_{\text{Loss}}^{\text{Loss}} \sum_{t, \in \Phi_t^l} P_{l}^{\text{Loss}}(t)
\]

where \( \mathbf{X}' \) is the decision variable set \( \mathbf{X} \) that does not contain \( C_{\text{ES}} \), \( C \) is the total cost expressed in formula (2) in the main manuscript, except that \( C_{\text{ES}} \) is a known quantity.

In the original clustered unit commitment (CUC) model (2)—(17) of the main manuscript, the following carbon emission constraints are added to offset the incremental CO₂ emissions by converting coal power to gas power.

\[
E^C = \sum_{t, \in \Phi_t^l} \sum_{t, \in \Phi_t^l} P_t^{\text{TG}}(t) + E^N = E^{(2)}
\]

where \( E^{(2)} \) is the CO₂ emissions in the second optimization removing the negative effects of plum rain.

2) Demand response (DR) program

First, adding the total DR cost in the objective function:

\[
\min_{\mathbf{X}} C + c_{\text{DR}}^{\text{DR}} \sum_{t, \in \Phi_t^l} P_{l}^{\text{DR}}(t)
\]

where \( P_{l}^{\text{DR}}(t) \) is the load curtailment at time \( t \), and \( c_{\text{DR}} \) is the unit compensation cost for DR program.

Then, using constraint (4b) to replace constraint (3) in the main manuscript, and adding the following constraints (4c-4e) in the CUC model.
\[
\sum_{t \in \Phi^T} P_{TG}^{T}(t) + \sum_{k \in \Phi^T} P_{WT}^{W}(t) + \sum_{i \in \Phi^T} P_{PV}^{P}(t) + \sum_{i \in \Phi^T} P_{PV}^{P}(t) + \sum_{n \in \Phi^T} P_{RG}^{R}(t)
\]
\[
+ \sum_{n \in \Phi^T} P_{n}^{TL}(t) + P_{ES}^{E}(t) - P_{ES}^{E}(t) + P_{DR}^{DR}(t) = P^{Load}(t) - P^{Loss}(t), \forall t \in \Phi^T
\]
\[
0 \leq P_{DR}^{DR}(t) \leq \beta \max\{P^{Load}(t)\}, \forall t \in \Phi^T
\]
\[
\sum_{t \in \Phi^T} P_{DR}^{DR}(t) \leq \Delta P^{PV}
\]
\[
e^C C \sum_{p \in \Phi^T} \sum_{q \in \Phi^T} P_{p}^{T}(t) + e^N \sum_{q \in \Phi^T} \sum_{q \in \Phi^T} P_{q}^{T}(t) = E^{(2)}
\]

Equation (4b) defines the supply and demand power balance considering DR program. Constraint (4c) bounds the minimum and maximum outputs of DR program, where \(\beta\) denotes the proportion of load curtailment to the total electric load. Constraint (4d) imposes the total load curtailment during the plum rain period less than the PV reductions. In the end, CO\(_2\) emission constraint (4e) is added to offset the incremental CO\(_2\) emissions.

3) Carbon capture, utilization and storage (CCUS)

Similarly like DR program, the objective function is changed as
\[
\min X^C + e^{CCUS} P^{CCUS}
\]
where \(P^{CCUS}\) is the power capacity of coal generators installed with CCUS, and \(e^{CCUS}\) is the capture cost per one unit of electricity.

Then, using constraint (5b) and (5c) to replace constraints (3) and (4) in the main manuscript, and adding the following constraints (5d)-(5f) in the clustered unit commitment model.
\[
\sum_{t \in \Phi^T} P_{TG}^{T}(t) + \sum_{k \in \Phi^T} P_{WT}^{W}(t) + \sum_{i \in \Phi^T} P_{PV}^{P}(t) + \sum_{i \in \Phi^T} P_{PV}^{P}(t) + \sum_{n \in \Phi^T} P_{RG}^{R}(t)
\]
\[
+ \sum_{n \in \Phi^T} P_{n}^{TL}(t) + P_{ES}^{E}(t) - P_{ES}^{E}(t) - \sigma^{CCUS} P^{CCUS} = P^{Load}(t) - P^{Loss}(t), \forall t \in \Phi^T
\]
\[
\sum_{t \in \Phi^T} P_{i}^{max} U_{i}(t) + \sum_{m \in \Phi^T} P_{m}^{RG}(t) + \sum_{n \in \Phi^T} P_{n}^{TL}(t) + S^{ES}(t-1)
\]
\[
- \sigma^{CCUS} P^{CCUS} \geq P^{Load}(t) + RS(t), \forall t \in \Phi^T
\]
\[
(\eta^{CCUS} - \sigma^{CCUS}) P^{CCUS} \leq \Delta P^{PV}
\]
\[
e^C C \sum_{p \in \Phi^T} \sum_{q \in \Phi^T} P_{p}^{T}(t) - e^{CCUS} C P^{CCUS} + e^N \sum_{q \in \Phi^T} \sum_{q \in \Phi^T} P_{q}^{T}(t) = E^{(2)}
\]

Equations (5b) and (5c) show the power balance and system reserve requirements considering CG with CCUS, respectively, where \(\eta^{CCUS}\) is the CCUS equipment efficiency, \(\sigma^{CCUS}\) is the ratio of consumed power by CCUS equipment. Constraint (5d) imposes the clean energy produced by plum rain period less than the PV reductions. In the end, CO\(_2\) emission constraint (5e) is added to offset the incremental CO\(_2\) emissions.

4) Long-duration (LD) energy storage

Similarly, the objective function of the UC model considering long-duration storage integration is given as follows:
where $P_{\text{max}}^{\text{LD}}$ and $S_{\text{max}}^{\text{LD}}$ are the installed power capacity and energy capacity of LD, respectively. $c_p^{\text{LD}}$ and $c_e^{\text{LD}}$ are the power capacity cost and energy capacity cost of LD, respectively. $r$ and $n^{\text{LD}}$ are the discount rate and lifetime of LD, respectively.

Then, using constraint (6b) to replace constraint (3) in the main manuscript, and adding the following constraints (6c)-(6g) in the CUC model.

\[
\begin{aligned}
&\sum_{i \in \Phi^{\text{TG}}} P_i^{\text{TG}}(t) + \sum_{k \in \Phi^{\text{WT}}} P_k^{\text{WT}}(t) + \sum_{l \in \Phi^{\text{PV}}} P_l^{\text{PV}}(t) + \sum_{m \in \Phi^{\text{RG}}} P_m^{\text{RG}}(t) \\
+ &\sum_{m \in \Phi^{\text{ES}}} P_m^{\text{ES}}(t) + P_{\text{ES}^-}(t) - P_{\text{ES}^+}(t) + P_{\text{LD}^-}(t) - P_{\text{LD}^+}(t) = P_{\text{Load}}(t) - P_{\text{Loss}}(t), \forall t \in \Phi^T
\end{aligned}
\]

(6b)

\[
\begin{aligned}
0 &\leq P_{\text{LD}^+}(t) \leq P_{\text{max}}^{\text{LD}}, \forall t \in \Phi^T \quad (6c) \\
0 &\leq P_{\text{LD}^-}(t) \leq P_{\text{max}}^{\text{LD}}, \forall t \in \Phi^T \quad (6d) \\
S_{\text{LD}}(t) &= S_{\text{LD}}(t-1) + \eta_{\text{LD}^+} P_{\text{LD}^+}(t) - P_{\text{LD}^-}(t) / \eta_{\text{LD}^-}, \forall t \in \Phi^T \\
0 &\leq S_{\text{LD}}(t) \leq S_{\text{max}}^{\text{LD}}, \forall t \in \Phi^T \quad (6e) \\
S_{\text{LD}}(0) &= S_{\text{max}}^{\text{LD}} \quad (6f) \\
\sum_{i \in \Phi^T} P_{\text{LD}^-}(t) - \sum_{i \in \Phi^T} P_{\text{LD}^+}(t) &\leq \Delta P_{\text{PV}} \quad (6g) \\
e^C \sum_{r \in \Phi^{\text{TG}}} \sum_{i \in \Phi^T} P_i^{\text{TG}}(t) + e^N \sum_{q \in \Phi^{\text{PV}}} \sum_{i \in \Phi^T} P_q^{\text{PV}}(t) &= E^{(2)} \quad (6i)
\end{aligned}
\]

Equation (6b) defines the supply and demand power balance considering LD storage. Constraints (6c)-(6f) impose power capacity and energy constraints, respectively, on the charging, discharging, and storage levels of LD storage, where $P_{\text{LD}^+/-}(t)$ is the hourly charging/discharging power of LD storage, $S_{\text{LD}}(t)$ is the hourly storage levels of LD storage, and $\eta_{\text{LD}^+/-}$ is the charging/discharging efficiency of LD storage. Constraints (6g) guarantees that the LD stores enough energy before the rainy season. Constraint (6h) imposes the net released energy during the plum rain period less than the PV reductions. In the end, CO2 emission constraint (6i) is added to offset the incremental CO2 emissions.
