Abstract

We obtain some restrictions on the topology of infinite volume hyperbolic manifolds. In particular, for any $n$ and any closed negatively curved manifold $M$ of dimension $\geq 3$, only finitely many hyperbolic $n$–manifolds are total spaces of orientable vector bundles over $M$.

1 Introduction

A hyperbolic manifold is, by definition, a quotient of a negatively curved symmetric space by a discrete isometry group that acts freely. Recall that negatively curved symmetric spaces are hyperbolic spaces over the reals, complex numbers, quaternions, or Cayley numbers.

The homotopy type of a hyperbolic manifold is determined by its fundamental group. Conversely, for finite volume hyperbolic manifolds, fundamental group determines the diffeomorphism type, thanks to the Mostow rigidity theorem. By contrast infinite volume hyperbolic manifolds with isomorphic fundamental groups can be very different topologically. For example, the total spaces of many plane bundles over closed surfaces carry hyperbolic metrics (this and other examples are discussed in the section 2).

In this paper we attempt to count hyperbolic manifolds up to intersection preserving homotopy equivalence. A homotopy equivalence \(f: N \to L\) of oriented \(n\)-manifolds is called intersection preserving if, for any \(k\) and any pair of (singular) homology classes \(\alpha \in H_k(N)\) and \(\beta \in H_{n-k}(N)\), their intersection number in \(N\) is equal to the intersection number of \(f_*\alpha\) and \(f_*\beta\) in \(L\). For example, any map that is homotopic to an orientation-preserving homeomorphism is an intersection preserving homotopy equivalence. Conversely, oriented rank two vector bundles over a closed oriented surface are isomorphic iff their total spaces are intersection preserving homotopy equivalent.

**Theorem 1.1** Let \(\pi\) be the fundamental group of a finite aspherical cell complex and let \(X\) be a negatively curved symmetric space. Let \(\rho_k\) be a sequence of discrete injective representations of \(\pi\) into the group of orientation-preserving isometries of \(X\). Suppose that \(\rho_k\) is precompact in the pointwise convergence topology.

Then the sequence of manifolds \(X/\rho_k(\pi)\) falls into finitely many intersection preserving homotopy equivalence classes.

The space of conjugacy classes of faithful discrete representations of a group \(\pi\) into the isometry group of a negatively curved symmetric space is compact provided \(\pi\) is finitely presented, not virtually nilpotent and does not split over a virtually nilpotent group (see 10.1). Since all the intersections in a hyperbolic manifold with virtually nilpotent fundamental group are zero (see 12.1), we get the following.
Corollary 1.2  Let $\pi$ be the fundamental group of a finite aspherical cell complex that does not split as an HNN–extension or a nontrivial amalgamated product over a virtually nilpotent group.

Then, for any $n$, the class of orientable hyperbolic $n$–manifolds with fundamental group isomorphic to $\pi$ breaks into finitely many intersection preserving homotopy equivalence classes.

A particular case of 1.2 was proved by Kapovich in [22]. Namely, he gave a proof for real hyperbolic $2m$–manifolds homotopy equivalent to a closed orientable negatively curved manifold of dimension $m \geq 3$.

If $\pi$ does split over a virtually nilpotent group, the space of representations is usually noncompact. For instance, this happens if $\pi$ is a surface group. Yet, for real hyperbolic $4$–manifolds homotopy equivalent to closed surfaces, Kapovich [22] proved a result similar to 1.2.

More generally, Kapovich [22] proved that there is a universal function $C(\cdot, \cdot)$ such that for any incompressible singular surfaces $\Sigma_{g_1}, \Sigma_{g_2}$ in an oriented real hyperbolic $4$–manifold we have $|\langle [\Sigma_{g_1}], [\Sigma_{g_2}] \rangle| \leq C(g_1, g_2)$. Reznikov [34] showed that for any singular surfaces $\Sigma_{g_1}, \Sigma_{g_2}$ in a closed oriented negatively curved $4$–manifold $M$ with the sectional curvature pinched between $-k^2$ and $-K^2$ there is a bound $|\langle [\Sigma_{g_1}], [\Sigma_{g_2}] \rangle| \leq C(g_1, g_2, k, K, \chi(M))$ for some universal function $C$.

Another way to classify hyperbolic manifolds is up to tangential homotopy equivalence. Recall that a homotopy equivalence of smooth manifolds $f: N \to L$ is called tangential if the vector bundles $f^* TL$ and $TN$ are stably isomorphic. For example, any map that is homotopic to a diffeomorphism is a tangential homotopy equivalence. Conversely, a tangential homotopy equivalence of open $n$–manifolds is homotopic to a diffeomorphism provided $n > 4$ and each of the manifolds is the total space of a vector bundle over a manifold of dimension $< n/2$ [25, pp 226–228].

An elementary argument (based on finiteness of the number of connected components of representation varieties and on finiteness of the number of symmetric spaces of a given dimension) yields the following.

Theorem 1.3  Let $\pi$ be a finitely presented group. Then, for any $n$, the class of complete locally symmetric nonpositively curved Riemannian $n$–manifolds with the fundamental group isomorphic to $\pi$ falls into finitely many tangential homotopy types.

Geometry & Topology, Volume 2 (1998)
Knowing both the intersection preserving and tangential homotopy types sometimes suffices to recover the manifold up to finitely many possibilities.

**Theorem 1.4** Let $M$ be a closed orientable negatively curved manifold of dimension $\geq 3$ and $n > \dim(M)$ be an integer. Let $f_k : M \to N_k$ be a sequence of smooth embeddings of $M$ into orientable hyperbolic $n$–manifolds such that $f_k$ induces monomorphisms of fundamental groups. Then the set of the normal bundles $\nu(f_k)$ of the embeddings breaks into finitely many isomorphism classes.

In particular, only finitely many orientable hyperbolic $n$–manifolds are total spaces of vector bundles over $M$.

In some cases it is easy to decide when there exist infinitely many rank $m$ vector bundles over a given base. For example, by a simple $K$–theoretic argument the set of isomorphism classes of rank $m$ vector bundles over a finite cell complex $K$ is infinite provided $m \geq \dim(K)$ and $\oplus_k H^{4k}(K, \mathbb{Q}) \neq 0$. Furthermore, oriented rank two vector bundles over $K$ are in one-to-one correspondence with $H^2(K, \mathbb{Z})$ via the Euler class. Note that many arithmetic closed real hyperbolic manifolds have nonzero Betti numbers in all dimensions [30]. Any closed complex hyperbolic manifold has nonzero even Betti numbers because the powers of the Kähler form are noncohomologous to zero. Similarly, for each $k$, closed quaternion hyperbolic manifolds have nonzero $4k$th Betti numbers.

Examples of vector bundles with hyperbolic total spaces are given in the section 2. Note that according to a result of Anderson [1] the total space of any vector bundle over a closed negatively curved manifold admits a complete metric with the sectional curvature pinched between two negative constants.

I am grateful to Bill Goldman, Misha Kapovich, and Jonathan Rosenberg for many helpful discussions. I would like to thank Heinz Helling and SFB-343 at the University of Bielefeld for support and hospitality.

**Outline of the paper.** The section 2 is a collection of examples of hyperbolic manifolds. Some invariants of maps and representations are defined in sections 3 and 4. Sections 5, 6, and 7 are devoted to a proof of the theorem 1.3 and other related results. Sections 8, 9, and 10 contain background on algebraic and geometric convergence needed for the main theorem which is proved in section 11. Theorems 1.1 and 1.2 are proved in section 12. Finally, theorem 1.4 is proved in section 13.
2 Examples

To help the reader appreciate the results stated above we collect some relevant examples of hyperbolic manifolds.

Example 2.1 (Plane bundles over closed surfaces) Total spaces of rank two vector bundles over closed surfaces often admit hyperbolic metrics. For instance, an orientable $\mathbb{R}^2$–bundle over a closed oriented surface of genus $g$ admits a real hyperbolic structure provided the Euler number $e$ of the bundle satisfies $|e| < g$ [27, 28] (cf [18], [21], [23, 24]). Complex hyperbolic structures exist on orientable $\mathbb{R}^2$–bundles over closed oriented surfaces when $|e + 2g - 2| < g$ [16].

Note that the Euler number is equal to the self-intersection number of the zero section, hence the total spaces of bundles with different Euler classes are not intersection homotopy equivalent.

For nonorientable bundles over nonorientable surfaces the condition $|e| \leq \lfloor \frac{g}{2} \rfloor$ on the twisted Euler number implies the existence of a real hyperbolic structure [3].

Example 2.2 (Plane bundles over closed hyperbolic 3–manifolds) Total spaces of plane bundles over closed hyperbolic 3–manifolds sometimes carry hyperbolic metrics [4].

In fact, it can be deduced from [4] that for every $k$ there exists a closed oriented real hyperbolic 3–manifold $M = M(k)$ and oriented real hyperbolic 5–manifolds $N_1, \ldots, N_k$ that are total spaces of plane bundles over $M$ and such that no two of them are intersection preserving homotopy equivalent.

Example 2.3 (Fundamental group at infinity) There are real hyperbolic 4–manifolds that are intersection homotopy equivalent but not homeomorphic to plane bundles over closed surfaces [18]. The invariant that distinguishes these manifolds from vector bundles is the fundamental group at infinity.

Even more surprising examples were given in [29] and [19]. Namely, there are orientable real hyperbolic 4–manifolds that are homotopy equivalent but not homeomorphic to handlebodies; these manifolds have nontrivial fundamental group at infinity. Note that if $N$ and $L$ are orientable 4–manifolds that are homotopy equivalent to a handlebody, then each homotopy equivalence $N \to L$ is both tangential and intersection preserving.
Example 2.4 (Nonorientable line bundles) Here is a simple way to produce homotopy equivalent hyperbolic manifolds that are not tangentially homotopy equivalent.

First, note that via the inclusion $O(n, 1) \hookrightarrow O(n+1, 1)$, any discrete subgroup of $O(n, 1)$ can be thought of as a discrete subgroup of $O(n+1, 1)$ that stabilizes a subspace $H_\mathbb{R}^n \subset H_\mathbb{R}^{n+1}$. The orthogonal projection $H_\mathbb{R}^{n+1} \to H_\mathbb{R}^n$ is an $O(n, 1)$-equivariant line bundle over $H_\mathbb{R}^n$. In particular, given a real hyperbolic manifold $M$, the manifold $M \times \mathbb{R}$ carries a real hyperbolic metric. If $H^1(M, \mathbb{Z}_2) \neq 0$, this construction can be twisted to produce nonorientable line bundles over $M = H_\mathbb{R}^n / \pi_1(M)$ with real hyperbolic metrics. Indeed, a nonzero element $w \in H^1(M, \mathbb{Z}_2) \cong \text{Hom}(\pi_1(M), \mathbb{Z}_2)$ defines an epimorphism $w: \pi_1(M) \to \mathbb{Z}_2$. Make $\mathbb{Z}_2$ act on $H_\mathbb{R}^{n+1}$ as the reflection in $H_\mathbb{R}^n$. Then let $\pi_1(M)$ act on line bundle $H_\mathbb{R}^n \times \mathbb{R} \cong H_\mathbb{R}^{n+1}$ by $\gamma(x, t) = (\gamma(x), w(\gamma)(t))$. The quotient $H_\mathbb{R}^{n+1} / \pi_1(M)$ is the total space of a line bundle over $M$ with the first Stiefel–Whitney class $w$.

In particular, line bundles with different first Stiefel–Whitney classes have total space that are homotopy equivalent but not tangentially homotopy equivalent. (Tangential homotopy equivalences preserve Stiefel–Whitney classes yet $w_1(H_\mathbb{R}^{n+1} / \pi_1(M)) = w_1(M) + w$.) Thus, we get many tangentially homotopy inequivalent manifolds in a given homotopy type.

3 Invariants of continuous maps

Definition 3.1 Let $B$ be a topological space and $S_B$ be a set. Let $\iota$ be a map that, given a smooth manifold $N$, and a continuous map from $B$ into $N$, produces an element of $S_B$. We call $\iota$ an invariant of maps of $B$ if the two following conditions hold:

1. Homotopic maps $f_1: B \to N$ and $f_2: B \to N$ have the same invariant.

2. Let $h: N \to L$ be a diffeomorphism of $N$ onto an open subset of $L$. Then, for any continuous map $f: B \to N$, the maps $f: B \to N$ and $h \circ f: B \to L$ have the same invariant.

There is a version of this definition for maps into oriented manifolds. Namely, we require that the target manifold is oriented and the diffeomorphism $h$ preserves orientation. In that case we say that $\iota$ is an invariant of maps of $B$ into oriented manifolds.
Example 3.2 (Tangent bundle) Assume $B$ is paracompact and $S_B$ is the set of isomorphism classes of real vector bundles over $B$. Given a continuous map $f: B \to N$, set $\tau(f: B \to N) = f^\# N$, the isomorphism class of the pullback of the tangent bundle to $N$ under $f$. Clearly, $\tau$ is an invariant.

Example 3.3 (Intersection number in oriented $n$–manifolds) Assume $B$ is compact. Fix two cohomology classes $\alpha \in H_m(B)$ and $\beta \in H_{n-m}(B)$. (In this paper we always use singular (co)homology with integer coefficients unless stated otherwise.)

Let $f: B \to N$ be a continuous map of a compact topological space $B$ into an oriented $n$–manifold $N$ where $\dim(N) = n$. Set $I_{n,\alpha,\beta}(f)$ to be the intersection number $I(f_\ast \alpha, f_\ast \beta)$ of $f_\ast \alpha$ and $f_\ast \beta$ in $N$. We next show that $I_{n,\alpha,\beta}$ is an integer-valued invariant of maps into oriented manifolds.

Recall that the intersection number $I(f_\ast \alpha, f_\ast \beta)$ can be defined as follows. Start with an arbitrary compact subset $K$ of $N$ that contains $f(B)$. Let $A \in H^{n-m}(N, N\setminus K)$ and $B \in H^m(N, N\setminus K)$ be the Poincaré duals of $f_*\alpha \in H_m(K)$ and $f_*\beta \in H_{n-m}(K)$, respectively. Then, set $I(f_\ast \alpha, f_\ast \beta) = \langle A \cup B, [N, N\setminus K] \rangle$ where $[N, N\setminus K]$ is the fundamental class of $N$ near $K$ [13, VII.13.5]. Note that

$$I(f_\ast \alpha, f_\ast \beta) = \langle A \cup B, [N, N\setminus K] \rangle = \langle A, B \cap [N, N\setminus K] \rangle = \langle A, f_\ast \beta \rangle.$$  

The following commutative diagram shows that $I(f_\ast \alpha, f_\ast \beta)$ is independent of $K$.

$$
\begin{array}{ccccccccc}
H_m(B) & \xrightarrow{f_*} & H_m(N, N\setminus f(B)) & \xrightarrow{D^{-1}} & H^{n-m}(f(B)) & \xrightarrow{f^*} & H^{n-m}(B) \\
f^* & \downarrow & i_* & & i^* & & \\
H_m(K) & \xrightarrow{i_*} & H_m(N, N\setminus K) & \xrightarrow{D^{-1}} & H^{n-m}(K) & \xrightarrow{f^*} & H^{n-m}(B)
\end{array}
$$

Note that $I_{n,\alpha,\beta}$ is an invariant. Indeed, property (1) holds trivially; property (2) is verified in [13, VIII.13.21(c)].

We say that an invariant of maps is liftable if in part (2) of the definition the word “diffeomorphism” can be replaced by a “covering map”. For example, tangent bundle is a liftable invariant. Intersection number is not liftable. The following proposition shows to what extent it can be repaired.

Proposition 3.4 Let $p: \tilde{N} \to N$ be a covering map of manifolds and let $B$ be a finite connected CW–complex. Suppose that $f: B \to \tilde{N}$ is a map such that $p \circ f: B \to N$ is an embedding (ie a homeomorphism onto its image).

Then $\iota(f) = \iota(p \circ f)$ for any invariant of maps $\iota$.

Geometry & Topology, Volume 2 (1998)
Proof Since \( p \circ f \colon B \to L \) is an embedding, so is \( f \). Then, the map \( p|_{f(B)} \colon f(B) \to p(f(B)) \) is a homeomorphism. Using compactness of \( f(B) \), one can find an open neighborhood \( U \) of \( f(B) \) such that \( p|_U \colon U \to p(U) \) is a diffeomorphism. Since invariants \( \iota(f) \) and \( \iota(p \circ f) \) can be computed in \( U \) and \( p(U) \), respectively, we conclude \( \iota(f) = \iota(p \circ f) \).

4 Invariants of representations

Assume \( X \) is a smooth contractible manifold and let \( \text{Diffeo}(X) \) be the group of all self-diffeomorphisms of \( X \) equipped with compact-open topology. Let \( \pi \) be the fundamental group of a finite-dimensional CW–complex \( \tilde{K} \) with universal cover \( \tilde{K} \).

We refer to a group homomorphism \( \rho \colon \pi \to \text{Diffeo}(X) \) as a representation. To any representation \( \rho \colon \pi \to \text{Diffeo}(X) \), we associate a continuous \( \rho \)-equivariant map \( \tilde{K} \to X \) as follows. Consider the \( X \)-bundle \( \tilde{K} \times_{\rho} X \) over \( K \) where \( \tilde{K} \times_{\rho} X \) is the quotient of \( \tilde{K} \times X \) by the following action of \( \pi \)

\[
\gamma(\tilde{k}, x) = (\gamma(\tilde{k}), \rho(\gamma)(x)), \quad \gamma \in \pi.
\]

Since \( X \) is contractible, the bundle has a section that is unique up to homotopy through sections. Any section can be lifted to a \( \rho \)-equivariant continuous map \( \tilde{K} \to \tilde{K} \times X \). Projecting to \( X \), we get a \( \rho \)-equivariant continuous map \( \tilde{K} \to X \).

Note that any two \( \rho \)-equivariant continuous maps \( \tilde{g}, \tilde{f} \colon \tilde{K} \to X \), are \( \rho \)-equivariantly homotopic. (Indeed, \( \tilde{f} \) and \( \tilde{g} \) descend to sections \( K \to \tilde{K} \times_{\rho} X \) that must be homotopic. This homotopy lifts to a \( \rho \)-equivariant homotopy of \( \tilde{f} \) and \( \tilde{g} \).)

Assume now that \( \rho(\pi) \) acts freely and properly discontinuously on \( X \). Then the map \( \tilde{f} \) descends to a continuous map \( f \colon K \to X/\rho(\pi_1(K)) \). We say that \( \rho \) is induced by \( f \).

Let \( \iota \) be an invariant of continuous maps of \( K \). Given a representation \( \rho \) such that \( \rho(\pi) \) acts freely and properly discontinuously on \( X \), set \( \iota(\rho) \) to be \( \iota(f) \) where \( \rho \) is induced by \( f \). We say \( \rho \) is an invariant of representations of \( \pi_1(K) \).

Similarly, any invariant \( \iota \) of continuous maps of \( K \) into oriented manifolds defines an invariant of representations into the group of orientation-preserving diffeomorphisms of \( X \).

Note that representations conjugate by a diffeomorphism \( \phi \) of \( X \) have the same invariants. (Indeed, if \( \tilde{f} \colon \tilde{K} \to X \) is a \( \rho \)-equivariant map, the map \( \phi \circ \tilde{f} \) is
The same is true for invariants of orientation-preserving representations when $\phi$ is orientation-preserving.

**Example 4.1 (Tangent bundle)** Let $\tau$ be the invariant of maps defined in 3.2. Then, for any representation $\rho$ such that $\rho(\pi)$ acts freely and properly discontinuously on $X$, let $\tau(\rho)$ be the pullback of the tangent bundle to $X/\rho(\pi)$ via a map $f: K \to X/\rho(\pi)$ that induces $\rho$.

In fact, $\tau$ can be defined for any representation as follows. Look at the “vertical” bundle $\tilde{K} \times_\rho TX$ over $\tilde{K} \times_\rho X$ where $TX$ is the tangent bundle to $X$. Set $\tau(\rho)$ to be the pullback of the vertical bundle via a section $K \to \tilde{K} \times_\rho X$. Thus, to every representation $\rho: \pi_1(K) \to \text{Diffeo}(X)$ we associated a vector bundle $\tau(\rho)$ of rank $\dim(X)$ over $K$.

**Example 4.2 (Intersection number for orientation preserving actions)** Assume the cell complex $K$ is finite and choose an orientation on $X$ (which makes sense because, like any contractible manifold, $X$ is orientable).

Fix two cohomology classes $\alpha \in H_m(K)$ and $\beta \in H_{n-m}(K)$. Let $I_{n,\alpha,\beta}$ is an invariant of maps defined in 3.3 where $n = \dim(X)$.

Let $\rho$ be a representation of $\pi$ into the group of orientation-preserving diffeomorphisms of $X$ such that $\rho(\pi)$ acts freely and properly discontinuously on $X$. Then let $I_{n,\alpha,\beta}(\rho)$ be the intersection number $I(f_*\alpha, f_*\beta)$ of $f_*\alpha$ and $f_*\beta$ in $X/\rho(\pi)$ where $f: K \to X/\rho(\pi)$ is a map that induces $\rho$.

**5 Spaces of representations and tangential homotopy equivalence**

Let $X$ be a smooth contractible manifold and let $\text{Diffeo}(X)$ be the group of all self-diffeomorphisms of $X$ equipped with compact–open topology. We equip the space of representations $\text{Hom}(\pi, \text{Diffeo}(X))$ with the pointwise convergence topology, ie a sequence of representations $\rho_k$ converges to $\rho$ provided $\rho_k(\gamma)$ converges to $\rho(\gamma)$ for each $\gamma \in \pi$.

In the next two sections we explore the consequences of the following observation.

**Proposition 5.1** Let $\rho_0$ and $\rho_1$ be injective representations of $\pi$ into $\text{Diffeo}(X)$ such that the groups $\rho_0(\pi)$ and $\rho_1(\pi)$ act freely and properly discontinuously on $X$. Suppose that $\rho_0$ and $\rho_1$ can be joined by a continuous path
of representations $\rho_t: \pi \to \text{Diffeo}(X)$ (where continuous means that, for every $\gamma \in \pi$, the map $\rho_t(\gamma): [0, 1] \to \text{Diffeo}(X)$ is continuous).

Then the homotopy equivalence of manifolds $X/\rho_0(\pi)$ and $X/\rho_1(\pi)$ induced by $\rho_1 \circ (\rho_0)^{-1}$ is tangential.

**Proof** Since $\rho_t: \pi \to \text{Diffeo}(X)$ is a continuous path of representations, the covering homotopy theorem implies that the bundles $\tau(\rho_0)$ and $\tau(\rho_1)$ are isomorphic (the invariant $\tau$ is defined in 4.1).

Let $f_0: K \to X/\rho_0(\pi)$ and $f_1: K \to X/\rho_1(\pi)$ be homotopy equivalences that induce $\rho_0$ and $\rho_1$, respectively. For $i = 1, 2$ the bundle $\tau(\rho_i)$ is isomorphic to the pullback of the tangent bundle to $X/\rho_i(\pi)$ via $f_i$. Thus $f_1 \circ (f_0)^{-1}$ is a tangential homotopy equivalence.

**Remark 5.2** In fact, the covering homotopy theorem implies that $\tau$ is constant on any path-connected component of the space $\text{Hom}(\pi_1(K), \text{Diffeo}(X))$.

**Corollary 5.3** Under the assumptions of 5.1, suppose that $\dim(X) \geq 5$ and that each of the manifolds $X/\rho_0(\pi)$ and $X/\rho_1(\pi)$ is homeomorphic to the total space of a vector bundle over a manifold of dimension $< \dim(X)/2$.

Then $\rho_0$ and $\rho_1$ are smoothly conjugate on $X$.

**Proof** According to [25, pp 226–228], the homotopy equivalence $f_1 \circ (f_0)^{-1}$ is homotopic to a diffeomorphism. Hence, $\rho_0$ and $\rho_1$ are smoothly conjugate on $X$.

**Remark 5.4** More precisely, the result proved in [25, pp 226–228] is as follows. Let $f: N_0 \to N_1$ be a tangential homotopy equivalence of smooth $n$–manifolds with $n \geq 5$. If each of the manifolds is homeomorphic to the interior of a regular neighbourhood of a simplicial complex of dimension $< n/2$, then $f$ is homotopic to a diffeomorphism.

### 6 Discrete representations in stable range

Suppose $X$ is a symmetric space of nonpositive sectional curvature. Note that for any discrete torsion-free subgroup $\Gamma \leq \text{Isom}(X)$ that stabilizes a totally geodesic submanifold $Y$, the exponential map identifies the quotient $X/\Gamma$ and the total space of normal bundle of $Y/\Gamma$ in $X/\Gamma$. Applying 5.1, we deduce the following.
Theorem 6.1 Let $X$ be a nonpositively curved symmetric space of dimension $\geq 5$ and let $\pi$ be a group. Let $\rho_1$ and $\rho_2$ be injective discrete representations of $\pi$ into the isometry group of $X$ that lie in the same path-connected component of the space $\text{Hom}(\pi, \text{Isom}(X))$. Suppose that each of the representation $\rho_1$ and $\rho_2$ stabilizes a totally geodesic subspace of dimension $< \dim(X)/2$.

Then $\rho_1$ and $\rho_2$ are smoothly conjugate on $X$.

Remark 6.2 Of course, the above argument works in other geometries as well. Here is a sample result for complete affine manifolds.

Let $\rho_0$ and $\rho_1$ be injective representations of a group $\pi$ into $\text{Aff}(\mathbb{R}^n)$ that lie in the same path-connected component of the space of representations $\text{Hom}(\pi, \text{Aff}(\mathbb{R}^n))$. Assume that the groups $\rho_0(\pi)$ and $\rho_1(\pi)$ act freely and properly discontinuously on $\mathbb{R}^n$ and, furthermore, suppose that $\rho_0(\pi)$ and $\rho_1(\pi)$ are contained in $\text{Aff}(\mathbb{R}^k) \subset \text{Aff}(\mathbb{R}^n)$.

Since the coordinate projection $\mathbb{R}^n \to \mathbb{R}^k$ is $\text{Aff}(\mathbb{R}^k)$–equivariant, the manifolds $\mathbb{R}^n/\rho_0(\pi)$ and $\mathbb{R}^n/\rho_1(\pi)$ are the total spaces of vector bundles over the manifolds $\mathbb{R}^k/\rho_0(\pi)$ and $\mathbb{R}^k/\rho_1(\pi)$, respectively. Then 5.3 implies that $\rho_0$ and $\rho_1$ are conjugate by a diffeomorphism of $\mathbb{R}^n$ provided $n \geq 5$ and $k < n/2$.

7 Locally symmetric nonpositively curved manifolds up to tangential homotopy equivalence

Let $G$ be a subgroup of $\text{Diffeo}(X)$ such that the space of representations $\text{Hom}(\pi, G)$ has finitely many path-connected components. Then 5.1 implies that the class of manifolds of the form $X/\rho(\pi)$ where $\rho$ is injective and $\rho(\pi)$ acts freely and properly discontinuously on $X$ falls into finitely many tangential equivalence classes.

For example, $\text{Hom}(\pi, G)$ has finitely many path-connected components if $\pi$ is finitely presented and $G$ is either real algebraic, or complex algebraic, or semisimple with finite center [15]. In particular, the following is true.

Theorem 7.1 Let $\pi$ be a finitely presented torsion-free group and let $X$ be a nonpositively curved symmetric space. Then the class of manifolds of the form $X/\rho(\pi)$, where $\rho \in \text{Hom}(\pi, \text{Isom}(X))$ is a faithful discrete representation, falls into finitely many tangential homotopy types.
Theorem 7.1 Let \( \pi \) be a finitely presented torsion-free group. Then, for any \( n \), the class of locally symmetric complete nonpositively curved \( n \)-manifolds with the fundamental group isomorphic to \( \pi \) falls into finitely many tangential homotopy types.

Proof For any \( n \) there exist only finitely many nonpositively curved symmetric spaces of dimension \( n \). Hence 7.1 applies.

8 Geometric convergence

In this section we discuss some basic facts on geometric convergence. The notion of geometric convergence was introduced by Chaubaty (see [7]). More details relevant to our exposition can be found in [11], [26] and [5]. In this section we let \( G \) be a Lie group equipped with some left invariant Riemannian metric.

Definition 8.1 Let \( C(G) \) be the set of all closed subgroups of \( G \). Define a topology on \( C(G) \) as follows. We say that a sequence \( \{ \Gamma_n \} \subset C(G) \) converges to \( \Gamma_{\text{geo}} \in C(G) \) geometrically if the following two conditions hold:

1. If \( \gamma_{n_k} \in \Gamma_{n_k} \) converges to \( \gamma \in G \), then \( \gamma \in \Gamma_{\text{geo}} \).
2. If \( \gamma \in \Gamma_{\text{geo}} \), then there is a sequence \( \gamma_n \in \Gamma_n \) with \( \gamma_n \to \gamma \) in \( G \).

Fact 8.2 ([11]) The space \( C(G) \) is compact and metrizable.

Fact 8.3 ([26]) \( \Gamma_n \to \Gamma_{\text{geo}} \) iff for every compact subset \( K \subset G \) the sequence \( \Gamma_n \cap K \to \Gamma_{\text{geo}} \cap K \) in the Hausdorff topology (ie for any \( \varepsilon > 0 \), there is \( N \) such that, if \( n > N \), then \( \Gamma_n \cap K \) lies in the \( \varepsilon \)-neighborhood of \( \Gamma_{\text{geo}} \cap K \) and \( \Gamma_{\text{geo}} \cap K \) lies in the \( \varepsilon \)-neighborhood of \( \Gamma_n \cap K \)).
Fact 8.4 ([26]) Let $\Gamma_{\text{geo}} \subset G$ is a discrete subgroup. Then there is $\varepsilon > 0$ such that, for any $\Gamma_n \to \Gamma_{\text{geo}}$ in $C(G)$ and any compact $K \subset G$, there is $N$ such that, if $n > N$ and $\gamma \in \Gamma_{\text{geo}} \cap K$, then there is a unique $\gamma_n \in \Gamma_n$ that is $\varepsilon$–close to $\gamma$.

In particular, $\Gamma_n$ is discrete for $n > N$, since $e \in \Gamma_n$ is the only element of $\Gamma_n$, that is in the $\varepsilon$–neighbourhood of the identity.

Remark 8.5 Let $\Gamma_n$ be a sequence of torsion-free groups converging to a discrete group $\Gamma_{\text{geo}}$ in $C(G)$. Then $\Gamma_{\text{geo}}$ is torsion-free. Indeed, choose $\gamma \in \Gamma_{\text{geo}}$ with $\gamma^k = e$. Find a sequence $\gamma_n \to \gamma$. Then $\gamma_n^k \to e$. By 8.4 we have $\gamma_n^k = e$ for large $n$. Since $\Gamma_n$ are torsion-free, $k = 1$ as desired.

Theorem 8.6 ([26]) Let $X$ be a simply connected homogeneous Riemannian manifold and $G$ be a transitive group of isometries. Let $\Gamma_n$ be a sequence of torsion-free subgroups of $G$ converging geometrically to a discrete subgroup $\Gamma_{\text{geo}}$. Let $U \subset X$ be a relatively compact open set.

Then, if $n$ is large enough, there exists a relatively compact open set $V$ with $U \subset V$ and smooth embeddings $\tilde{\varphi}_n : U \to V$ such that $\tilde{\varphi}_n$ descend to embeddings $\varphi_n : U/\Gamma_{\text{geo}} \to V/\Gamma_n$.

\[
\begin{array}{ccc}
U & \xrightarrow{\tilde{\varphi}_n} & V \\
\downarrow p & & \downarrow p_n \\
U/\Gamma_{\text{geo}} & \xrightarrow{\varphi_n} & V/\Gamma_n
\end{array}
\]

The embeddings $\varphi_n$ converge $C^r$–uniformly to the inclusion.

Sketch of the Proof Let $K = \{ g \in G : g(V) \cap \overline{V} \neq \emptyset \}$, so $K$ is compact. By 8.4, if we take $n$ sufficiently large, then for any $\gamma \in \Gamma_{\text{geo}} \cap K$ there exists a unique $\gamma_n \in \Gamma_n$ that is close to $\gamma$. It defines an injective map $r_n$ of $\Gamma_{\text{geo}} \cap K$ into $\Gamma_n$.

Our goal is to construct embeddings $\varphi_n : U \to V$ that are close to the inclusion and $r_n$–equivariant (in the sense that $\varphi_n(\gamma(x)) = r_n(\gamma) \varphi_n(x)$ for $\gamma \in \Gamma_{\text{geo}}$).

The construction is non-trivial and we refer to [26] for a complete proof.

Lemma 8.7 Let $G$ be a Lie group and $\Gamma_n$ be a sequence of discrete groups that converges geometrically to $\Gamma = \Gamma_{\text{geo}}$. If the identity component $\Gamma_0$ of $\Gamma_{\text{geo}}$ is compact, the sequence $\{ \Gamma_n \}$ has unbounded torsion (ie for any positive integer $N$, there is $\gamma \in \Gamma_n(N)$ of finite order which is greater than $N$).
Proof Choose \( \epsilon > 0 \) so small that the closed \( 4\epsilon \)-neighborhood \( U \) of \( \Gamma_0 \) is disjoint from \( \Gamma \setminus \Gamma_0 \) (this is possible since \( \Gamma_0 \) is compact). Given \( M > 1 \), for large \( n \), \( \Gamma_n \) and \( \Gamma \) are \( \epsilon/M \)-Hausdorff close on the compact set \( U \). Take an arbitrary element \( g \in \Gamma_0 \) in \( \epsilon \)-neighborhood of the identity \( e \) and choose \( g_n \in \Gamma_n \) so that it is \( \epsilon/M \)-close to \( g \).

First, show that \( g_n \) has finite order. Suppose not. Since \( U \) is compact and \( \langle g_n \rangle \) is discrete and infinite, there is a smallest \( k \) with \( (g_n)^k \notin U \). So, \( (g_n)^{-1} \in U \). The metric is left invariant, hence,

\[
d((g_n)^{-1}, (g_n)^k) = d(g_n, e) < d(g, e) + d(g_n, g) < \epsilon + \epsilon/M < 2\epsilon.
\]

Since \( \Gamma_n \) and \( \Gamma \) are \( \epsilon/M \)-Hausdorff close on \( U \) and since \( \Gamma \cap U = \Gamma_0 \), we get

\[
d((g_n)^{-1}, (g_n)^k, \Gamma_0) < \epsilon/M < \epsilon.
\]

This implies \( d((g_n)^{-1}, \Gamma_0) < 3\epsilon \) and, thus, \( (g_n)^k \in U \), a contradiction. Thus \( g_n \) has finite order.

We have just showed that any neighborhood of \( g \) contains an element of finite order \( g_n \in \Gamma_n \) (for \( n \) large enough). So we get a sequence \( g_n \) converging to \( g \). Assume the torsion of \( \Gamma_n \) is uniformly bounded by \( N \). Then, for any finite order element \( h \in \Gamma_n \), we have \( h^{N_1} = e \). In particular \( e = (g_n)^{N_1} \) converges to \( g^{N_1} \). We, thus, proved that any element \( g \) in \( \Gamma_0 \) that is \( \epsilon \)-close to the identity satisfies \( g^{N_1} = e \). This is absurd. (Indeed, it would mean that the map \( \Gamma_0 \to \Gamma_0 \) that takes \( g \) to \( g^{N_1} \) maps the \( \epsilon \)-neighborhood of the identity to the identity. But the map is clearly a diffeomorphism on some neighborhood of the identity.) Thus, \( \Gamma_n \) has unbounded torsion as desired. \( \square \)

Lemma 8.8 Let \( G \) be a Lie group and let \( \Gamma_n \) be a sequence of discrete groups that converges geometrically to \( \Gamma = \Gamma_{geo} \). Then the identity component \( \Gamma_0 \) of \( \Gamma_{geo} \) is nilpotent.

Proof Denote the identity component by \( G_0 \). The group \( \Gamma_{geo} \) is closed, so it is a Lie group. So the identity component \( \Gamma_0 \) of \( \Gamma_{geo} \) is a Lie group; we are to show that \( \Gamma_0 \leq G_0 \) is nilpotent. Let \( U \) be a neighborhood of the identity that lies in a Zassenhaus neighborhood in \( G_0 \) (see [33, 8.16]). Being a Lie group \( \Gamma_0 \) is generated by any neighborhood of the identity, in particular by \( V = U \cap \Gamma_0 \). To show \( \Gamma_0 \) is nilpotent, it suffices to check that, for some \( k \), \( V(k) = \{e\} \), that is, any iterated commutator of weight \( k \) with entries in \( V \) is trivial [33, 8.17]. Fix an iterated commutator \( [v_1 \ldots [v_{k-2}[v_{k-1}, v_k]]] \) with \( v_k \in V \) and choose a sequence \( g_k^n \to v_k \) where \( g_k^n \in \Gamma_n \). For \( n \) large enough, the elements \( g_k^n, \ldots g^n_k \) lie in a Zassenhaus neighborhood. Then by Zassenhaus–Kazhdan–Margulis lemma [33, 8.16] the group \( \langle g_k^n, \ldots g_k^n \rangle \) lies in a connected nilpotent Lie subgroup of \( G_0 \). The class of any connected nilpotent
Lie subgroup of $G_0$ is bounded by $\dim(G_0)$. Thus, for $k > \dim(G_0)$, the $k$–iterated commutator $[g_1^n \ldots [g_{k-2}^n [g_{k-1}^n, g_k^n]] \ldots]$ is trivial, for large $n$. This implies $[v_1 \ldots [v_{k-2} [v_{k-1}, v_k] \ldots]$ is trivial and, therefore, $\Gamma_0$ is nilpotent.

9 Algebraic convergence

The set of representations $\text{Hom}(\pi, G)$ of a group $\pi$ into a topological group $G$ can be given the so-called algebraic topology (also called pointwise convergence topology). Namely, a sequence of representations $\rho_k$ converges to $\rho$ provided $\rho_k(\gamma)$ converges to $\rho(\pi)$ for each $\gamma \in \pi$. In this section we discuss how algebraic and geometric convergences interact.

It follows from definitions that geometric limit always contains the algebraic one. More precisely, if $\rho_k$ converges to $\rho$ algebraically and $\rho_k(\pi)$ converges to $\Gamma_{geo}$ geometrically, then $\rho_k(\pi) \subset \Gamma_{geo}$. In particular, if $\Gamma_{geo}$ is discrete, so is $\rho(\pi)$.

**Theorem 9.1** Let $\pi$ be a finitely generated group and let $X$ be a negatively curved symmetric space. Let $\rho_k \in \text{Hom}(\pi, G)$ be a sequence of representations converging algebraically to a representation $\rho$ where, for every $k$, the group $\rho_k(\pi)$ is discrete and the sequence $\{\rho_k(\pi)\}$ has uniformly bounded torsion. Suppose that $\rho(\pi)$ is an infinite group without nontrivial normal nilpotent subgroups.

Then the closure of $\{\rho_k(\pi)\}$ in the geometric topology consists of discrete groups. In particular, the group $\rho(\pi)$ is discrete.

**Proof** Passing to subsequence, we can assume that $\{\rho_k(\pi)\}$ converges geometrically to $\Gamma_{geo}$. Being a closed subgroup $\Gamma_{geo}$ is a Lie group. Suppose, arguing by contradiction, that the identity component $\Gamma_0$ of $\Gamma_{geo}$ is nontrivial. By lemma 8.8, $\Gamma_0$ is a nilpotent Lie group.

Since $\rho(\pi)$ does not have a nontrivial normal nilpotent subgroup, $\rho(\pi) \cap \Gamma_0 = \{e\}$, so $\rho(\pi)$ is discrete. Using the Selberg lemma we find a torsion-free subgroup $\Pi \leq \rho(\pi)$ of finite index. The group $\Pi$ is infinite since $\rho(\pi)$ is. Notice that the group $\Pi$ may have at most two fixed points at infinity (any isometry that fixes at least three points is elliptic [2, p 84]). The next goal is to show that $\Pi$ is virtually nilpotent.

According to [9, 3.3.1], the nilpotence of $\Gamma_0$ implies one the following mutually exclusive conclusions:
Case 1 \( \Gamma_0 \) has a fixed point in \( X \) (hence \( \Gamma_0 \) is compact which is is impossible by 8.7).

Case 2 \( \Gamma_0 \) fixes a point \( p \in \partial X \) and acts freely on \( X \cup \partial X \setminus \{p\} \).

Since \( \Pi \) normalizes \( \Gamma_0 \) (in fact, \( \Gamma_0 \) is a normal subgroup of \( \Gamma_{\text{geo}} \)) it has to fix \( p \) too. If \( p \) is the only fixed point of \( \Pi \), then every nontrivial element of \( \Pi \) is parabolic [14, 8.9P]. Any parabolic preserves horospheres centered at \( p \) [2, p 84], therefore, according to [8] \( \Pi \) is virtually nilpotent.

If \( \Pi \) fixes two points at infinity, then it acts freely and properly discontinuously on the geodesic joining the points. Hence \( \Pi \cong \mathbb{Z} \), the fundamental group of a circle.

Case 3 \( \Gamma_0 \) has no fixed points in \( X \) and preserves setwise some bi-infinite geodesic. In this case the fixed point set of \( \Gamma_0 \) is the endpoints \( p \) and \( q \) of the geodesic. Indeed, \( \Gamma_0 \) fixes each of the endpoints, since \( \Gamma_0 \) is connected. Assume \( \Gamma_0 \) fixes some other point of \( \partial X \). Then any element of \( \Gamma_0 \) is elliptic (see [2, p 85]) and, as such, it fixes the bi-infinite geodesic pointwise. Thus \( \Gamma_0 \) has a fixed point in \( X \) which contradicts the assumptions of Case 3.

Since \( \Pi \) normalizes \( \Gamma_0 \), it leaves the set \( \{p,q\} \) invariant. Moreover, \( \Pi \) preserves \( \{p,q\} \) pointwise because \( \Pi \) contains no elliptics (any isometry that flips \( p \) and \( q \) has a fixed point on the geodesic joining \( p \) and \( q \)). Therefore, \( \Pi \cong \mathbb{Z} \) as before. Hence, \( \Pi \) is virtually nilpotent.

Thus, \( \rho(\pi) \) has a nilpotent subgroup of finite index and, therefore, has a normal nilpotent subgroup of finite index. This contradicts the assumption that \( \rho(\pi) \) is an infinite group without nontrivial normal nilpotent subgroups. \( \square \)

**Remark 9.2** Let \( \Gamma \) be a torsion-free discrete subgroup of \( \text{Isom}(X) \) that has a nontrivial normal nilpotent subgroup. Then \( \Gamma \) is, in fact, virtually nilpotent. Indeed, repeating the arguments above, we see that \( \Gamma \) fixes a point at infinity and, hence, is virtually nilpotent. Conversely, any virtually nilpotent group clearly has a normal nilpotent subgroup of finite index.

**Lemma 9.3** Let \( G \) be a Lie group and let \( \pi \) be a finitely generated group without nontrivial normal nilpotent subgroups. Let \( \rho_k \in \text{Hom}(\pi, G) \) be a sequence of discrete faithful representations that converges algebraically to a representation \( \rho \). Then \( \rho \) is faithful.

**Proof** Denote the identity component of \( G \) by \( G_0 \). It suffices to prove that the group \( K = \text{Ker}(\rho) \) is nilpotent. Let \( V \) be a set of generators for \( K \) (maybe infinite). To show \( K \) is nilpotent, it suffices to check that, for some \( m \), \( V^{(m)} = \{e\} \),
that is, any iterated commutator of weight $m$ with entries in $V$ is trivial \[33, 8.17\]. Fix an iterated commutator \([v_1 \ldots [v_{m-2}[v_{m-1}, v_m]] \ldots]\) with $v_m \in V$.

For $k$ large enough, the elements $\rho_k(v_1), \ldots, \rho_k(v_m)$ lie in a Zassenhaus neighborhood of $G_0$. Then by Zassenhaus–Kazhdan–Margulis lemma \[33, 8.16\] the group $\langle \rho_k(v_1), \ldots, \rho_k(v_m) \rangle$ lies in a connected nilpotent Lie subgroup of $G_0$. The class of any nilpotent subgroup of $G_0$ is bounded by $\dim(G_0)$. Thus, for $m > \dim(G_0)$, the $m$–iterated commutator
\[
[\rho_k(v_1) \ldots [\rho_k(v_{m-2})[\rho_k(v_{m-1}), \rho_k(v_m)]] \ldots]
\]
is trivial, for large $k$. Since $\rho_k$ is faithful $[v_1 \ldots [v_{m-2}[v_{m-1}, v_m]] \ldots]$ is trivial and we are done.

**Corollary 9.4** Let $X$ be a negatively curved symmetric space and let $\pi$ be a finitely generated, torsion-free, discrete subgroup of $\text{Isom}(X)$ that is not virtually nilpotent. Then the set of faithful discrete representations of $\pi$ into $\text{Isom}(X)$ is a closed subset of $\text{Hom}(\pi, \text{Isom}(X))$.

**Proof** Let a sequence $\rho_k$ of faithful discrete representations converge to $\rho \in \text{Hom}(\pi, \text{Isom}(X))$. According to 9.2 the group $\pi$ has no normal nilpotent subgroup. Then 9.3 implies $\rho$ is faithful. By compactness $\rho_k(\pi)$ has a subsequence that converges geometrically to $\Gamma_{\text{geo}}$ which is a discrete group by 9.1. Therefore, $\rho(\pi) \subset \Gamma_{\text{geo}}$ is also discrete as wanted.

**Corollary 9.5** Let $X$ be a negatively curved symmetric space and let $\pi$ be a finitely generated, torsion-free, discrete subgroup of $\text{Isom}(X)$ that is not virtually nilpotent. Suppose $\rho_k$ is a sequence of injective, discrete representations of $\pi$ into $\text{Isom}(X)$ that converges algebraically. Then the closure of $\{\rho_k(\pi)\}$ in the geometric topology consists of discrete groups.

**Proof** Combine 9.1, 9.2, and 9.4.

**10 A compactness theorem**

In this section we state a compactness theorem for the space of conjugacy classes of faithful discrete representations of a group $\pi$ into the isometry group of a negatively curved symmetric space. The proof follows from the work of Bestvina and Feighn \[6\] based on ideas of Rips (see the review of \[6\] by Paulin in

*Geometry & Topology, Volume 2 (1998)*
Let $X$ be a negatively curved symmetric space and $\text{Isom}(X)$ be the isometry group of $X$. We equip $\text{Hom}(\pi, \text{Isom}(X))$ with the algebraic topology.

**Theorem 10.1** Let $X$ be a negatively curved symmetric space and let $\pi$ be a discrete, finitely presented subgroup of the isometry group of $X$. Suppose that $\pi$ is not virtually nilpotent and does not split as an HNN–extension or a nontrivial amalgamated product over a virtually nilpotent group. Then the space of conjugacy classes of faithful discrete representations of $\pi$ into $\text{Isom}(X)$ is compact.

Here is an example of a group that does not split over a virtually nilpotent group.

**Proposition 10.2** Let $M$ be a closed aspherical $n$–manifold such that any nilpotent subgroup of $\pi_1(M)$ has cohomological dimension $\leq n - 2$. Then $\pi_1(M)$ does not split as a nontrivial amalgamated product or HNN–extension over a virtually nilpotent group.

**Proof** Assume, by contradiction, that $\pi = \pi_1(M)$ is of the form $\Gamma_1 \ast_N \Gamma_2$ or $\Gamma_0 \ast_N$ where $N$ is a virtually nilpotent group and $\Gamma_k$ is a proper subgroup of $\pi$, for $k = 0, 1, 2$.

First, suppose that both $\Gamma_1$ and $\Gamma_2$ have infinite index in $\pi$. Note that by the definition of HNN–extension, $\Gamma_0$ has infinite index in $\pi$. Then it follows from the Mayer–Vietoris sequence [10, VII.9.1, VIII.2.2.4(c)] that

$$\text{cd}(\pi) \leq \max_k (\text{cd}(\Gamma_k), \text{cd}(N) + 1).$$

The cohomological dimension of $\pi = \pi_1(M)$ is $n$ because $M$ is a closed aspherical $n$–manifold. Since $|\pi: \Gamma_k| = \infty$, $\Gamma_k$ is the fundamental group of a noncompact manifold of dimension $n$, hence $\text{cd}(\Gamma_k) < \text{cd}(\pi)$. Finally, $\text{cd}(N) \leq n - 2$ and we get a contradiction.

Second, assume that $\pi = \Gamma_1 \ast_N \Gamma_2$ and, say, $\Gamma_1$ has finite index in $\pi$. Look at the map $i_*: H_n(\Gamma_1) \to H_n(\pi)$ induced by the inclusion $i: \Gamma_1 \to \pi$ in the homology with $w_1(M)$–twisted integer coefficients. It is proved in [10, III.9.5(b)] that the image of $i_*$ is generated by $|\pi: \Gamma_1| \cdot [M]$ where $[M]$ is the fundamental class of $M$. 

*Geometry & Topology, Volume 2 (1998)*
Since $\Gamma_1$ has finite index in $\pi$, the group $N$ is of finite index in $\Gamma_2$ because $N = \Gamma_1 \cap \Gamma_2$. In particular, $\text{cd}(\Gamma_2) = \text{cd}(N) \leq n - 2$ [10, VIII.3.1].

Look at the $n$th term of the Mayer–Vietoris sequence with $w_1(M)$–twisted integer coefficients [10, VII.9.1]:

$$\cdots \to H_n N \to H_n \Gamma_1 \oplus H_n \Gamma_2 \to H_n \Gamma \to H_{n-1} N \to \cdots$$

Using the cohomological dimension assumption on $N$, we get $0 = H_n(N) = H_{n-1}(N) = H_n(\Gamma_2)$, and hence the inclusion $i: \Gamma_1 \to \pi$ induces an isomorphism of $n$th homology.

Thus $|\pi: \Gamma_1| = 1$ which contradicts the assumption the $\Gamma_1$ is a proper subgroup of $\pi$.

**Corollary 10.3** Let $M$ be a closed aspherical manifold of dimension $\geq 3$ with word-hyperbolic fundamental group. Then $\pi_1(M)$ does not split as a nontrivial amalgamated product or HNN–extension over a virtually nilpotent group.

**Proof** It is well known that any virtually nilpotent subgroup of a word-hyperbolic group is virtually cyclic. Since any virtually cyclic group has cohomological dimension one, proposition 10.2 applies.

### 11 The Main theorem

Throughout this section $\iota$ is an invariant of continuous maps of $K$ into oriented manifolds. We also use the letter $\iota$ for the corresponding invariant of discrete representations. Let $\pi$ be the fundamental group of a finite CW–complex $K$.

**Theorem 11.1** Let $X$ be a contractible homogeneous Riemannian manifold and $G$ be a transitive group of orientation-preserving isometries. Let $\rho_k \in \text{Hom}(\pi, G)$ be a sequence of representations such that

- the groups $\rho_k(\pi)$ are torsion-free, and
- $\rho_k$ converges algebraically to $\rho$, and
- $\rho_k(\pi)$ converges geometrically to a discrete group $\Gamma_{\text{geo}}$.

Let $f: K \to X/\Gamma_{\text{geo}}$ be a continuous map that induces the homomorphism $\rho: \pi \to \rho(\pi) \subset \Gamma_{\text{geo}}$. Then $\iota(\rho_k) = \iota(f)$ for all large $k$.
Proof According to 8.4, we can assume that the groups \( \rho_k(\pi) \) are discrete. Being a limit of torsion-free groups the discrete group \( \Gamma_{\text{geo}} \) is itself torsion-free by 8.5. Thus \( \Gamma_{\text{geo}} \) acts freely and properly discontinuously on \( X \), so \( X/\Gamma_{\text{geo}} \) is a manifold.

We consider the universal covering \( q: \tilde{K} \to K \). Since \( K \) is a finite complex, one can choose a finite connected subcomplex \( D \subset \tilde{K} \) with \( q(D) = K \). (Pick a representing cell in every orbit, the union of the cells is a finite subcomplex that is mapped onto \( Y \) by \( q \). Adding finitely many cells, one can assume the complex is connected.)

According to section 4, the representation \( \rho \) defines a continuous \( \rho \)-equivariant map \( \tilde{f}: \tilde{K} \to X \) which is unique up to \( \rho \)-equivariant homotopy. The map \( \tilde{f} \) descends to a continuous map \( \bar{f}: K \to X/\rho(\pi) \).

The identity map \( \text{id}: X \to X \) is equivariant with respect to the inclusion \( \rho(\pi) \hookrightarrow \Gamma_{\text{geo}} \), therefore, \( \tilde{f} \) is equivariant with respect to the homomorphism \( \rho: \pi \to \Gamma_{\text{geo}} \). We denote by \( f \) the composition of \( \tilde{f} \) and the covering \( X/\rho(\pi) \to X/\Gamma_{\text{geo}} = N \) induced by the inclusion \( \rho(\pi) \subset \Gamma_{\text{geo}} \).

Let \( U \subset X \) be an open relatively compact neighborhood of \( \tilde{f}(D) \). We are in position to apply Theorem 8.6. Thus, if \( k \) is large enough, there is a sequence of embeddings \( \varphi_k: U \to V \subset X \) that converges to the inclusion and is \( r_k \)-equivariant (recall that \( r_k \) was defined in the proof of 8.6). So the map \( \varphi_k \circ \tilde{f}: D \to V \) is \( r_k \circ \rho \)-equivariant. By the very definition of \( r_k \) we have \( r_k \circ \rho = \rho_k \) whenever the left hand side is defined. We now extend the map \( \varphi_k \circ \tilde{f}: D \to V \) by equivariance to a \( \rho_k \)-equivariant map \( \xi_k: \tilde{K} \to X \). The map \( \xi_k \) descends to \( \xi_k: K \to V/\rho_k(\pi) \subset X/\rho_k(\pi) \). Notice that by construction \( \xi_k = \varphi_k \circ \tilde{f} \).

Since \( \varphi_k \) converges to the inclusion, \( \varphi_k \) is orientation-preserving for large \( k \). Thus \( \iota(\xi_k) = \iota(f) \) for large \( k \) because \( \iota \) is an invariant of maps into oriented manifolds.

Notice that \( \iota(\xi_k) = \iota(\rho_k) \) since the map \( \xi_k \) is \( \rho_k \)-equivariant (according to section 4 any \( \rho_k \)-equivariant map can be used to define \( \iota(\rho_k) \)). Therefore, for large \( k \), \( \iota(\rho_k) = \iota(f) \) as desired. \( \square \)

Remark 11.2 Let \( X \) be a negatively curved symmetric space. Then, according to 9.1, the assumption “\( \Gamma_{\text{geo}} \) is discrete” of the theorem 11.1 can be replaced by “\( \rho_k(\pi) \) are discrete and \( \rho(\pi) \) is an infinite group without nontrivial normal nilpotent subgroups”.

Remark 11.3 In some cases the conclusion of the theorem 11.1 can be improved to “\( \iota(\rho_k) = \iota(\rho) \) for all large \( k \)”.

Since \( \iota(\rho) = \iota(\tilde{f}) \), it suffices to show that \( \iota(\tilde{f}) = \iota(f) \).
This is clearly true when $\rho(\pi) = \Gamma_{\text{geo}}$ in which case it is usually said that $\rho_k$ converges to $\rho$ strongly. Another obvious example is when $\iota$ is a liftable invariant. Finally, according to 3.4, $\iota(f) = \iota(f)$ provided $f$ is homotopic to an embedding (ie a homeomorphism onto its image).

**Corollary 11.4** Let $X$ be a negatively curved symmetric space and let $K$ be a finite cell complex such that $\pi = \pi_1(K)$ is a torsion-free, not virtually nilpotent, discrete subgroup of $\text{Isom}(X)$. Let $\rho_k$ be a sequence of discrete injective representations of $\pi$ into the group of orientation-preserving isometries of $X$. Suppose that $\rho_k$ converges in the pointwise convergence topology. Then $\iota(\rho_k) = \iota(\rho_{k+1})$ for all large $k$.

**Proof** The result follows from 11.1 and 9.5.

**Remark 11.5** The results of this section certainly hold if $\iota$ is any invariant of maps rather that an invariant of maps into oriented manifolds. For such a $\iota$ we do not have to assume that the isometry groups preserve orientation.

### 12 Hyperbolic manifolds up to intersection preserving homotopy equivalence

A homotopy equivalence $f: N \to L$ of oriented $n$–manifolds is called *intersection preserving* if, for any $m$ and any pair of (singular) homology classes $\alpha \in H_m(N)$ and $\beta \in H_{n-m}(N)$, their intersection number in $N$ is equal to the intersection number of $f_*\alpha$ and $f_*\beta$ in $L$. For example, any map that is homotopic to an orientation-preserving homeomorphism is an intersection preserving homotopy equivalence [13, 13.21].

**Proposition 12.1** Let $N$ be an oriented hyperbolic manifold with virtually nilpotent fundamental group. Then the intersection number of any two homology classes in $N$ is zero.

**Proof** It suffices to prove that $N$ is homeomorphic to $\mathbb{R} \times Y$ for some space $Y$. First note that any torsion-free, discrete, virtually nilpotent group $\Gamma$ acting on a hyperbolic space $X$ must have either one or two fixed points at infinity (see the proof of 9.1). If $\Gamma$ has only one fixed point, $\Gamma$ is parabolic and, hence, it preserves all horospheres at the fixed point. Therefore, if $H$ is such a horosphere, $X/\Gamma$ is homeomorphic to $\mathbb{R} \times H/\Gamma$. If $\Gamma$ has two fixed points, $\Gamma$ preserves a bi-infinite geodesic. Hence $X/\Gamma$ is the total space of a vector bundle over a circle and the result easily follows.
**Theorem 12.2** Let $\pi$ be the fundamental group of a finite aspherical cell complex and let $X$ be a negatively curved symmetric space. Let $\rho_k$ be a sequence of discrete injective representations of $\pi$ into the group of orientation-preserving isometries of $X$. Suppose that $\rho_k$ is precompact in the pointwise convergence topology.

Then the sequence of manifolds $X/\rho_k(\pi)$ falls into finitely many intersection preserving homotopy equivalence classes.

**Proof** According to 12.1, we can assume that $\pi_1(K)$ is not virtually nilpotent. Argue by contradiction. Pass to a subsequence so that no two of the manifolds $X/\rho_k(\pi)$ are intersection preserving homotopy equivalent and so that $\rho_k$ converges algebraically.

Being the fundamental group of a finite aspherical cell complex, $\pi$ has finitely generated homology. Choose a finite set of generators of $H_*(\pi)$. Using 11.4 we pass to a subsequence so that $I_{n,\alpha,\beta}(\rho_k) = I_{n,\alpha,\beta}(\rho_{k+1})$ for any pair of generators $\alpha \in H_m(N)$ and $\beta \in H_{n-m}(N)$. Hence, the homotopy equivalence that induces $\rho_{k+1} \circ (\rho_k)^{-1}$ is intersection preserving. \[\square\]

**Theorem 12.3** Let $K$ be a finite connected cell complex such that $\pi_1(K)$ does not split as an HNN-extension or a nontrivial amalgamated product over a virtually nilpotent group. Then, given a nonnegative integer $n$ and homology classes $\alpha \in H_m(K)$ and $\beta \in H_{n-m}(K)$, there exists $C > 0$ such that,

1. for any continuous map $f: K \to N$ of $K$ into an oriented hyperbolic $n$–manifold $N$ that induces an isomorphism of fundamental groups, and

2. for any embedding $f: K \to N$ of $K$ into an oriented hyperbolic $n$–manifold $N$ that induces a monomorphism of fundamental groups,

the intersection number of $f_*\alpha$ and $f_*\beta$ in $N$ satisfies $|(f_*\alpha, f_*\beta)| \leq C$.

**Proof** First, we prove (1). Arguing by contradiction, consider a sequence of maps $f_k: K \to N_k$ that induce $\pi_1$–isomorphisms of $K$ and oriented hyperbolic $n$–manifolds $N_k$ and such that $I_{n,\alpha,\beta}(f_k)$ is an unbounded sequence of integers. Pass to a subsequence so that no two integers $I_{n,\alpha,\beta}(f_k)$ are the same. Each map $f_k$ induces an injective discrete representation $\rho_k$ of $\pi_1(K)$ into the group of orientation-preserving isometries of a negatively curved symmetric space; in particular $I_{n,\alpha,\beta}(\rho_k) = I_{n,\alpha,\beta}(f_k)$. Since in every dimension there are no more than four negatively curved symmetric spaces, we can pass to a subsequence to ensure that all the symmetric spaces where $\rho_k(\pi_1(K))$ acts are isometric.
According to 12.1, we can assume that $\pi_1(K)$ is not virtually nilpotent. By 10.1 there exists a sequence of orientation-preserving isometries $\phi_k$ of $X$ such that the sequence $\phi_k \circ \rho_k \circ (\phi_k)^{-1}$ is algebraically precompact. As we explained in the section 4, $I_{n,\alpha,\beta}(\rho_k) = I_{n,\alpha,\beta}(\phi_k \circ \rho_k \circ (\phi_k)^{-1})$. Thus 11.4 provides a contradiction. Finally, according to 3.4, (1) implies (2).

**Corollary 12.4** Let $\pi$ be the fundamental group of a finite aspherical cell complex that does not split as an HNN–extension or a nontrivial amalgamated product over a virtually nilpotent group. Then, for any $n$, the class of hyperbolic $n$–manifolds with fundamental group isomorphic to $\pi$ breaks into finitely many intersection preserving homotopy equivalence classes.

**Proof** By 12.1, we can assume that $\pi_1(K)$ is not virtually nilpotent. Thus the result follows from 12.2 and 10.1.

### 13 Vector bundles with hyperbolic total spaces

I am most grateful to Jonathan Rosenberg for explaining to me the following nice fact.

**Proposition 13.1** Let $K$ be a finite CW–complex and $m$ be a positive integer. Then the set of isomorphism classes of oriented real (complex, respectively) rank $m$ vector bundles over $K$ with the same rational Pontrjagin classes and the rational Euler class (rational Chern classes, respectively) is finite.

**Proof** To simplify notation we only give a proof for complex vector bundles and then indicate necessary modifications for real vector bundles. We need to show that the “Chern classes map” $(c_1, \ldots, c_m): [K, BU(m)] \to H^*(K, \mathbb{Q})$ is finite-to-one. First, notice that $c_1$ classifies line bundles [20, I.3.8, I.4.3.1], so we can assume $m > 1$.

The integral $i$th Chern class $c_i \in H^*(BU(m), \mathbb{Z}) \cong [BU(m), K(\mathbb{Z}, 2i)]$ can be represented by a continuous map $f_i: BU(m) \to K(\mathbb{Z}, 2i)$ such that $c_i = f_i^*(\alpha_{2i})$ where $\alpha_{2i}$ is the fundamental class of $K(\mathbb{Z}, 2i)$. (Recall that, by the Hurewicz theorem $H_{n-1}(K(\mathbb{Z}, n), \mathbb{Z}) = 0$ and $H_n(K(\mathbb{Z}, n), \mathbb{Z}) \cong \mathbb{Z}$; the class in $H^n(K(\mathbb{Z}, n), \mathbb{Z}) \cong \text{Hom}(H_n(K(\mathbb{Z}, n), \mathbb{Z}); \mathbb{Z})$ corresponding to the identity homomorphism is called the fundamental class and is denoted $\alpha_n$.)
It defines “Chern classes map”

\[ c = (f_1, \ldots, f_m) : BU(m) \to K(\mathbb{Z}, 2) \times \cdots \times K(\mathbb{Z}, 2m). \]

We now check that the map induces an isomorphism on rational cohomology. According to [17, 7.5, 7.6] for even \( n \), \( H^n(K(\mathbb{Z}, n), \mathbb{Q}) \cong \mathbb{Q}[\alpha_n] \). By the Künneth formula

\[ H^*(\times_{i=1}^m K(\mathbb{Z}, 2i), \mathbb{Q}) \cong \otimes_{i=1}^m H^*(K(\mathbb{Z}, 2i), \mathbb{Q}) \cong \otimes_{i=1}^m \mathbb{Q}[\alpha_{2i}] \cong \mathbb{Q}[\alpha_2, \ldots, \alpha_{2m}] \]

and under this ring isomorphism \( \alpha_{2i}^* \times \cdots \times \alpha_{2m}^* \) corresponds to \( \alpha_{2i}^* \cdots \alpha_{2m}^* \).

It is well known that \( H^*(BU(m), \mathbb{Q}) \cong \mathbb{Q}[c_1, \ldots, c_m] \) [31, 14.5]. Thus the homomorphism \( c^* : H^*(\times_{i=1}^m K(\mathbb{Z}, 2i), \mathbb{Q})) \to H^*(BU(m), \mathbb{Q}) \) defines a homomorphism \( \mathbb{Q}[\alpha_2, \ldots, \alpha_{2m}] \cong \mathbb{Q}[c_1, \ldots, c_m] \) that takes \( \alpha_{2i} \) to \( c_i \). Since this is an isomorphism, so is \( c^* \) as promised.

Therefore \( c \) induces an isomorphism on rational homology. Then, since \( BU(m) \) is simply connected, the map \( c \) must be a rational homotopy equivalence [17, 7.7]. In other words the homotopy theoretic fiber \( F_c \) of the map \( c \) has finite homotopy groups.

Consider an oriented rank \( m \) vector bundle \( f : K \to BU(m) \) with characteristic classes \( c \circ f : K \to \times_{i=1}^m K(\mathbb{Z}, 2i) \). Our goal is to show that the map \( c \circ f \) has at most finitely many nonhomotopic liftings to \( BU(m) \). Look at the set of liftings of \( c \circ f \) to \( BU(m) \) and try to construct homotopies skeleton by skeleton using the obstruction theory. The obstructions lie in the groups of cellular cochains of \( K \) with coefficients in the homotopy groups of \( F_c \). (Note that the fibration \( F_c \to BU(m) \to \times_{i=1}^m K(\mathbb{Z}, 2i) \) has simply connected base and fiber (since \( m > 1 \), so the coefficients are not twisted.) Since the homotopy groups of \( F_c \) are finite, there are at most finitely many nonhomotopic liftings. This completes the proof for complex vector bundles.

For oriented real vector bundles of odd rank the same argument works with \( c = (p_1, \ldots, p_{[m/2]}) \), where \( p_i \) is the \( i \)th Pontrjagin class. Similarly, for oriented real vector bundles of even rank we set \( c = (e, p_1, \ldots, p_{[m/2]-1}) \), where \( e \) is the Euler class. (The case \( m = 2 \) can be treated separately: since \( SO(2) \cong U(1) \) any oriented rank two vector bundle has a structure of a complex line bundle with \( e \) corresponding to \( c_1 \). Thus, according to [20, I.3.8, I.4.3.1], oriented rank two vector bundles are in one-to-one correspondence with \( H^2(K, \mathbb{Z}) \)).

**Remark 13.2** A similar result is probably true for nonorientable bundles. However, the argument given above fails due to the fact \( BO(m) \) is not simply connected (ie the map \( c = (p_1, \ldots, p_{[m/2]}) \) of \( BO(m) \) to the product of Eilenberg–MacLane spaces is not a rational homotopy equivalence even though
it induces an isomorphism on rational cohomology). For simplicity, we only deal with oriented bundles.

**Remark 13.3** Note that, if either \( m \) is odd or \( m > \dim(K) \), the rational Euler class is zero, and, hence rational Pontrjagin classes determine an oriented vector bundle up to a finite number of possibilities.

**Corollary 13.4** Let \( M \) be a closed smooth manifold and let \( m \) be an integer such that either \( m \) is odd or \( m > \dim(M) \). Let \( f_k : B \to N_k \) be a sequence of smooth immersions of \( B \) into complete locally symmetric nonpositively curved Riemannian manifolds \( N_k \) with orientable normal bundle and \( \dim(N_k) = m + \dim(M) \).

Then the set of the normal bundles \( \nu(f_k) \) of the immersions falls into finitely many isomorphism classes.

**Proof** We can assume that all the manifolds \( N_k \) are quotients of the same symmetric space \( X \) since in every dimension there exist only finitely many symmetric spaces.

According to section 4, the immersions \( f_k \) induce representations \( \rho_k : \pi_1(M) \to \text{Isom}(X) \) such that \( \tau(f_k) = \tau(\rho_k) \). The sequence \( \tau(\rho_k) \) of vector bundles breaks into finitely many isomorphism classes because the representation variety \( \text{Hom}(\pi_1(M), \text{Isom}(X)) \) has finitely many connected components (see 7.1). In particular, there are only finitely many possibilities for the total Pontrjagin class of \( \tau(\rho_k) \).

The normal bundle of the immersion \( f_k \) satisfies \( \nu(f_k) \oplus TM \cong \tau(f_k) \). Applying the total Pontrjagin class, we get \( p(\nu(f_k)) \cup p(TM) = p(\tau(f_k)) \). The total Pontrjagin class of any bundle is a unit, hence we can solve for \( p(\nu(f_k)) \). Thus, there are only finitely many possibilities for \( p(\nu(f_k)) \). Finally, 13.1 and 13.3 imply that there are only finitely many possibilities for \( \nu(f_k) \). \( \Box \)

**Theorem 13.5** Let \( M \) be a closed negatively curved manifold of dimension \( \geq 3 \) and let \( n > \dim(M) \) be an integer. Let \( f_k : B \to N_k \) be a sequence of smooth embeddings of \( M \) into hyperbolic \( n \)-manifolds such that for each \( k \)

- \( f_k \) induces a monomorphism of fundamental groups, and
- the normal bundle \( \nu(f_k) \) of the embedding \( f_k \) is orientable.

Then the set of the normal bundles \( \nu(f_k) \) falls into finitely many isomorphism classes. In particular, up to diffeomorphism, only finitely many hyperbolic \( n \)-manifolds are total spaces of orientable vector bundles over \( M \).
Proof  Passing to covers corresponding to \( f_k^* \), we can assume that \( f_k : M \to N_k \) induce isomorphisms of fundamental groups. Arguing by contradiction, assume that \( \nu_k = \nu(f_k) \) are pairwise nonisomorphic.

Arguing as in the proof of 13.4, we deduce that there are only finitely many possibilities for the total Pontrjagin classes of \( \nu_k \). Thus, according to 13.1, we can pass to a subsequence so that the (rational) Euler classes of \( \nu_k \) are all different. Denote the integral Euler class by \( e(\nu_k) \).

First, assume that \( M \) is orientable. Recall that, by definition, the Euler class \( e(\nu_k) \) is the image of the Thom class \( \tau(\nu_k) \in H^m(N_k, N_k \setminus f_k(M)) \) under the map \( f_k^*: H^m(N_k, N_k \setminus f_k(M)) \to H^m(M) \). According to [13, VIII.11.18] the Thom class has the property \( \tau(\nu_k) \cap [N_k, N_k \setminus f_k(M)] = f_k^*[M] \) where \([N_k, N_k \setminus f_k(M)]\) is the fundamental class of the pair \((N_k, N_k \setminus f_k(M))\) and \([M]\) is the fundamental class of \( M \).

Therefore, for any \( \alpha \in H^m(M) \), the intersection number of \( f_k^*\alpha \) and \( f_k^*[M] \) in \( N_k \) satisfies

\[
I(f_k^*[M], f_k^*\alpha) = \langle \tau(\nu_k), f_k^*\alpha \rangle = \langle f^*\tau(\nu_k), \alpha \rangle = \langle e(\nu_k), \alpha \rangle.
\]

Since \( M \) is compact, \( H^m(M) \) is finitely generated; we fix a finite set of generators. The (rational) Euler classes are all different, hence the homomorphisms \( \langle e(\nu_k), - \rangle \in \text{Hom}(H^m(M), \mathbb{Z}) \) are all different. Then there exists a generator \( \alpha \in H^m(M) \) such that \( \{\langle e(\nu_k), \alpha \rangle\} \) is an infinite set of integers. Hence \( \{I(f_k^*[M], f_k^*\alpha)\} \) is an infinite set of integers. Combining 12.3 and 10.3, we get a contradiction.

Assume now that \( M \) is nonorientable. Let \( q : \tilde{M} \to M \) be the orientable two-fold cover. Any finite cover of aspherical manifolds induces an injection on rational cohomology [10, III.9.5(b)]. Hence \( e(q^#\nu_k) = q^*e(\nu_k) \) implies that the rational Euler classes of the pullback bundles \( q^#\nu_k \) are all different, and there are only finitely many possibilities for the total Pontrjagin classes of \( q^#\nu_k \).

Furthermore, the bundle map \( q^#\nu_k \to \nu_k \) induces a smooth two-fold cover of the total spaces, thus the total space of \( q^#\nu_k \) is hyperbolic. Finally, \( \tilde{M} \) is a closed orientable negatively curved manifold. Thus, we get a contradiction as in the oriented case. \( \square \)
