We present a rigorous analysis of the phenomenon of decoherence for general N-level systems coupled to reservoirs of free massless bosonic fields. We apply our general results to the specific case of the qubit. Our approach does not involve master equation approximations and applies to a wide variety of systems which are not explicitly solvable.

I. INTRODUCTION

We examine rigorously the phenomenon of quantum decoherence. This phenomenon is brought about by the interaction of a quantum system, called in what follows “the system S”, with an environment, or “reservoir R”. Decoherence is reflected in the temporal decay of off-diagonal elements of the reduced density matrix of the system in a given basis. The latter is determined by the measurement to be performed. To our knowledge, this phenomenon has been analyzed rigorously so far only for explicitly solvable models, see e.g. [1–7]. In this paper we consider the decoherence phenomenon for quite general non-solvable models. Our analysis is based on the modern theory of resonances for quantum statistical systems as developed in [8–15] (see also the book [16]), which is related to resonance theory in non-relativistic quantum electrodynamics [9, 17].

Let $\mathcal{H} = \mathcal{H}_S \otimes \mathcal{H}_R$ be the Hilbert space of the system interacting with the environment, and let

$$H = H_S \otimes \mathbb{1}_R + \mathbb{1}_S \otimes H_R + \lambda \nu$$

be its Hamiltonian. Here, $H_S$ and $H_R$ are the Hamiltonians of the system and the reservoir, respectively, and $\lambda \nu$ is an interaction with a coupling constant $\lambda \in \mathbb{R}$. In the following we will omit trivial factors $\mathbb{1}_S \otimes \mathbb{1}_R$. The reservoir is taken initially in an equilibrium state at some temperature $T = 1/\beta > 0$. Let $\rho_t$ be the density matrix of the total system at time $t$. The reduced density matrix (of the system S) at time $t$ is then formally given by

$$\rho_t = \text{Tr}_R \rho_t,$$

where $\text{Tr}_R$ is the partial trace with respect to the reservoir degrees of freedom. Formulas (1) and (2) describe the situation where a state of the reservoir is given by a well-defined density matrix on the Hilbert space $\mathcal{H}_R$. In order to describe decoherence and thermalization we need to consider “true” (dispersive) reservoirs, obtained for instance by taking a thermodynamic limit, or a continuous-mode limit. We refer to [18] for a detailed description of such reservoirs, which is not needed in the presentation of our results here.

Let $\rho(\beta, \lambda)$ be the equilibrium state of the interacting system at temperature $T = 1/\beta$ and set $\rho_t(\beta, \lambda) = \text{Tr}_R \rho_t(\beta, \lambda)$. There are three possible scenarios for the asymptotic behaviour of the reduced density matrix as $t \to \infty$:

(i) $\rho_t \to \rho_{\infty} = \rho(\beta, \lambda)$,

(ii) $\rho_t \to \rho_{\infty} \neq \rho(\beta, \lambda)$,

(iii) $\rho_t$ does not converge.

The first situation is generic while the last two are not, although they are of interest, e.g. for energy conserving, or quantum non-demolition interactions characterized by $[H_S, \nu] = 0$, see [3, 18].

Decoherence is a basis-dependent notion. It is usually defined as the vanishing of the off-diagonal elements $[\rho_t]_{m,n}$, $m \neq n$ in the limit $t \to \infty$, in a chosen basis. Most often decoherence is defined w.r.t. the basis of eigenvectors of the system Hamiltonian $H_S$ (the energy, or computational basis for a quantum register), though other bases, such as the position basis for a particle in a scattering medium [3], are also used.

Since $\rho_t(\beta, \lambda)$ is generically non-diagonal in the energy basis, the off-diagonal elements of $\rho_t$ will not vanish in the generic case, as $t \to \infty$. Thus, strictly speaking, decoherence in this case should be defined as the decay (convergence) of the off-diagonals of $\rho_t$ to the corresponding off-diagonals of $\rho(\beta, \lambda)$. The latter are $O(\lambda)$. If these terms are neglected then decoherence manifests itself as a process in which initially coherent superpositions of basis
elements $\psi_j$ become incoherent statistical mixtures,

$$\sum_{j,k} c_{j,k} |\psi_j\rangle \langle \psi_k| \rightarrow \sum_j p_j |\psi_j\rangle \langle \psi_j|, \quad \text{as } t \rightarrow \infty.$$  

In particular, phase relations encoded in the $c_{j,k}$ disappear for large times.

II. GENERAL RESULTS

We consider $N$-dimensional quantum systems interacting with reservoirs of massless free quantum fields (photons, phonons or other massless excitations) through an interaction $v = G \otimes \varphi(g)$, see also (1) and (6). Here, $G$ is a hermitian $N \times N$ matrix and $\varphi(g)$ is the bosonic field operator smoothed out with the form factor $g(k), k \in \mathbb{R}^3$. For any observable $A$ of the system we set

$$\langle A \rangle_t := \text{Tr}_S(\mathcal{T}_t A) = \text{Tr}_{S+R}(\rho_t (A \otimes \mathbb{1}_R)). (3)$$

Assuming certain regularity conditions on $g(k)$ (allowing e.g. $g(k) = |k|^p e^{-|k|^m} g_1(\sigma)$ where $g_1$ is a function on the sphere and where $p = -1/2 + n, n = 0, 1, \ldots, m = 1, 2$), we show that the ergodic averages

$$\langle \langle A \rangle \rangle_\infty := \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T \langle A \rangle_t \, dt$$

exist, i.e., that $\langle A \rangle_t$ converges in the ergodic sense as $t \rightarrow \infty$. Furthermore, we show that for $t \geq 0$, and for any $0 < \tau' < \frac{2\pi}{p}$,

$$\langle A \rangle_t - \langle \langle A \rangle \rangle_\infty = \sum_{\varepsilon \neq 0} e^{\varepsilon t} R_\varepsilon(A) + O(\lambda^2 e^{-\tau'/2}), (4)$$

where the complex numbers $\varepsilon$ are the eigenvalues of a certain explicitly given operator $K(\tau')$, lying in the strip $\{z \in \mathbb{C} \mid 0 \leq \text{Im} z < \tau'/2\}$. They have the expansions

$$\varepsilon \equiv \varepsilon^{(s)} = -\lambda^2 \delta^{(s)} + O(\lambda^4), (5)$$

where $\varepsilon \in \text{spec}(H_S \otimes \mathbb{1}_S - \mathbb{1}_S \otimes H_S) = \text{spec}(H_S) - \text{spec}(H_S)$ and the $\delta^{(s)}$ are the eigenvalues of a matrix $\Delta_s$, called a level-shift operator, acting on the eigenspace of $H_S \otimes \mathbb{1}_S - \mathbb{1}_S \otimes H_S$ corresponding to the eigenvalue $e$ (which is a subspace of $\mathbb{1}_S \otimes H_S$). The level shift operators play a central role in the ergodic theory of open quantum systems, see e.g. [18, 19].

The coefficients $R_\varepsilon(A)$ in (4) are linear functionals of $A$ which depend on the initial state $\rho_0$ and the Hamiltonian $H$. They have the expansion $R_\varepsilon(A) = \sum_{(m,n) \in I_s} \varkappa_{m,n} A_{m,n} + O(\lambda^2)$, where $I_s$ is the collection of all pairs of indices such that $e = E_m - E_n$, the $E_k$ being the eigenvalues of $H_S$. Here, $A_{m,n}$ is the $(m,n)$-matrix element of the observable $A$ in the energy basis of $H_S$, and the $\varkappa_{m,n}$ are coefficients depending on the initial state of the system (and on $e$, but not on $A$ nor on $\lambda$).

III. QUBIT

Our results for the qubit can be summarized as follows. Consider a linear coupling,

$$v = \begin{bmatrix} a & c \\ \tau & b \end{bmatrix} \otimes \varphi(g), (6)$$

where $\varphi(g)$ is the Bose field operator above. The form-factor $g \in L^2(\mathbb{R}^3, d^3k)$ contains an ultra-violet cutoff which introduces a time-scale $\tau_{UV}$. This time scale depends on the physical system in question. We can think of it as coming from some frequency-cutoff determined by a characteristic length scale beyond which the interaction decreases rapidly. For instance, for a phonon field $\tau_{UV}$ is naturally identified with the inverse of the Debye frequency. We assume $\tau_{UV}$ to be much smaller than the time scales considered here.

A key role in the decoherence analysis is played by the infrared behaviour of form factors $g(k)$. We characterize this behaviour by the unique $p \geq -1/2$ satisfying

$$0 < \lim_{|k| \rightarrow 0} \frac{|g(k)|}{|k|^p} = C < \infty. (7)$$

The power $p$ depends on the physical model considered, e.g. for quantum-optical systems $p = 1/2$. We can treat $p = -1/2 + n, n = 0, 1, \ldots$.

Decoherence in models with interaction (6) with $c = 0$ is considered in [1–6, 18, 21–23]. This is the situation of a non-demolition (energy conserving) interaction, where $[v, H_S] = 0$, and consequently energy-exchange processes are suppressed. The resulting decoherence is called phase-decoherence. A particular model of phase-decoherence is obtained by the so-called position-position coupling, where the matrix in the interaction (6) is the Pauli matrix $\sigma_z [2, 6, 22, 23]$. On the other hand, energy-exchange processes, responsible for driving the system to equilibrium, have a probability proportional to $|c|^{2n}$, for some $n \geq 1$ (and $a, b$ do not enter) [9, 10, 13, 15, 19, 20]. Thus the property $c \neq 0$ is important for thermalization (return to equilibrium).

We express the energy-exchange effectiveness by the function

$$\xi(\eta) = \lim_{\varepsilon \rightarrow 0} \frac{1}{\pi} \int_{S^2} d^3k \coth \left( \frac{\beta |k|}{2} \right) |g(k)|^2 \frac{\varepsilon}{(|k| - \eta)^2 + \varepsilon^2},$$

where $\eta \geq 0$ represents the energy at which processes between the qubit and the reservoir take place. Let $\Delta = E_2 - E_1 > 0$ be the energy gap of the qubit. In works on convergence to equilibrium it is usually assumed that $|c|^2 \xi(\Delta) > 0$. This condition is called the “Fermi Golden Rule Condition”. It means that the interaction induces second-order ($\lambda^2$) energy exchange processes at the Bohr frequency of the qubit (emission and absorption of reservoir quanta). The condition $c \neq 0$ is actually necessary for thermalization while $\xi(\Delta) > 0$ is not (higher order processes can drive the system to equilibrium). Observe
that $\xi(\Delta)$ converges to a fixed function, as $T \to 0$, and increases exponentially as $T \to \infty$. The expression for decoherence times involves also $\xi(0)$, see (10).

Our analysis allows to describe the dynamics of systems which exhibit both thermalization and (phase) decoherence.

Let the initial density matrix, $\rho_{t=0}$, be of the form $\overline{\rho}_0 \otimes \rho_{\beta}$. (Our method does not require the initial state to be a product, see [18].) Denote by $\rho_{m,n}$ the operator represented in the energy basis by the $2 \times 2$ matrix whose entries are zero, except the $(n,m)$ entry which is one. We show that for $t \geq 0$

$$\begin{align*}
[\rho_t]_{1,1} - \langle\langle p_{1,1}\rangle\rangle_\infty &= e^{it\varepsilon_0(\lambda)} [C_0 + O(\lambda^2)] \\
&+ e^{it\varepsilon_\Delta(\lambda)}O(\lambda^2) + e^{it(-\varepsilon_\Delta(\lambda))}O(\lambda^2) + O(\lambda^2 e^{-tr'/2})
\end{align*}$$

and

$$\begin{align*}
[\rho_t]_{1,2} - \langle\langle p_{2,1}\rangle\rangle_\infty &= e^{it\varepsilon_\Delta(\lambda)} [C_\Delta + O(\lambda^2)] \\
&+ e^{it\varepsilon(\lambda)}O(\lambda^2) + e^{it(-\varepsilon_\Delta(\lambda))}O(\lambda^2) + O(\lambda^2 e^{-tr'/2}).
\end{align*}$$

Here, $C_0, C_\Delta$ are explicit constants depending on the initial condition $\overline{\rho}_0$, but not on $\lambda$, and the resonance energies $\varepsilon$ have the expansions

$$\begin{align*}
\varepsilon_0(\lambda) &= i\lambda^2 \pi^2 |c|^2 \xi(\Delta) + O(\lambda^4) \\
\varepsilon_\Delta(\lambda) &= \Delta + \lambda^2 R + \frac{1}{2} \lambda^2 \pi^2 \left[ |c|^2 \xi(\Delta) + (b - a)^2 \xi(0) \right] \\
&+ O(\lambda^4)
\end{align*}$$

(10)

and $\varepsilon_{-\Delta}(\lambda) = -\varepsilon_\Delta(\lambda)$, with the real number

$$R = \frac{1}{2} (b^2 - a^2) \langle g, \omega^{-1} g \rangle + \frac{1}{2} |c|^2 P.V. \int_{\mathbb{R} \times S^2} u^2 |g(|u|, \sigma)|^2 \coth \left( \frac{\beta |u|}{2} \right) \frac{1}{u - \Delta}.$$

The error terms in (8), (9) and (10) satisfy (for small $\lambda$): \[ \frac{O(\lambda^2)}{\lambda^2} \leq C \] and \[ \sup_{\lambda \geq 0} \frac{O(\lambda^2 e^{-tr'/2})}{\lambda^2 e^{-tr'/2}} \leq C. \]

To our knowledge this is the first time that formulas for the decay of off-diagonal matrix elements of the reduced density matrix are obtained for models which are not explicitly solvable, and without using uncontrolled master equation approximations (see e.g. [22] and references therein).

Remarks. 1) The corresponding expressions for the matrix elements $[\rho_t]_{1,2}$ and $[\rho_t]_{2,1}$ are obtained from the relations $[\rho_t]_{1,2} = 1 - [\rho_t]_{1,1}$ (conservation of unit trace) and $[\rho_t]_{2,1} = [\rho_t]_{1,2}$ (hermiticity of $\rho_t$).

2) If the qubit is initially in one of the logic pure states $\overline{\rho}_0 = |\varphi_j\rangle\langle\varphi_j|$, where $H \varphi_j = E_j \varphi_j$, $j = 1, 2$, then we find $C_\Delta = 0$, and $C_0 = e^{i\Delta/2} (e^{i\Delta} + 1)^{-3/2}$ for $j = 1$ and $C_0 = e^{i\Delta} (e^{i\Delta} + 1)^{-3/2}$ for $j = 2$, see [18].

3) To second order in $\lambda$, the imaginary part of $\varepsilon_\Delta$ is increased by a term $\propto (b - a)^2 \xi(0)$ only if $p = -1/2$, where $p$ is defined in (7). For $p > -1/2$ we have $\xi(0) = 0$ and that contribution vanishes. For $p < -1/2$ we have $\xi(0) = \infty$.

4) It is easy to see that $\xi(\Delta)$ and $R$ contain purely quantum, vacuum fluctuation terms as well as thermal ones, while $\xi(0)$ is determined entirely by thermal fluctuations; it is proportional to $\beta^{-1} = T$.

5) The second order difference $D_{\beta}$ defined by 

$$D_{\beta} = \text{Im} \xi(\lambda) - \text{Im} \xi(\lambda) = \lambda^2 D + O(\lambda^4), \quad D = \frac{1}{2} \pi^2 \left[ |c|^2 \xi(\Delta) - (b - a)^2 \xi(0) \right].$$

For $D > 0$ the populations converge to their limiting values faster than the off-diagonal matrix elements, as $t \to \infty$ (coherence persists beyond thermalization of the populations). For $D < 0$ the off-diagonal elements converge faster. If the interaction matrix is diagonal ($c = 0$) then $D \leq 0$, if it is off-diagonal then $D \geq 0$.

6) For energy-conserving interactions, $c = 0$, it follows that full decoherence occurs if and only if $b \neq a$ and $\xi(0) > 0$. If either of these conditions are not satisfied then the off-diagonal matrix elements are purely oscillatory (while the populations are constant), see also [18].

Illustration. Let the initial state of $S$ be given by a coherent superposition in the energy basis,

$$\overline{\rho}_0 = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}.$$  

(11)

We obtain the following expressions for the dynamics of the reduced matrix elements, for all $t \geq 0$:

$$\begin{align*}
[\rho_t]_{m,m} &= e^{-\beta E_m} + \frac{(-1)^m}{2 \xi(\lambda)} e^{it\xi(\lambda)} \\
&+ R_{m,m}(\lambda, t), \quad m = 1, 2, \\
[\rho_t]_{1,2} &= \frac{1}{2} e^{it\xi(\lambda)} + R_{1,2}(\lambda, t), \\
[\rho_t]_{2,1} &= \frac{1}{2} e^{it\xi(\lambda)} + R_{2,1}(\lambda, t),
\end{align*}$$

where the numbers $\varepsilon$ are given in (10). The remainder terms satisfy $|R_{m,n}(\lambda, t)| \leq C \lambda^2$, uniformly in $t \geq 0$, and they can be decomposed into a sum of a constant part (in $t$) and a decaying one, $R_{m,n}(\lambda, t) = \langle\langle p_{m,n}\rangle\rangle_\infty - \delta_{m,n} e^{-\beta \frac{\varepsilon_{m,n}}{\lambda^2}} + R_{m,n}(\lambda, t)$, where $|R_{m,n}(\lambda, t)| = O(\lambda^2 e^{-\gamma t})$, with $\gamma = \min\{\text{Im} \xi(0), \text{Im} \xi(\Delta)\}$. Therefore, to second order in $\lambda$, convergence of the populations to the equilibrium values (Gibbs law), and decoherence occur exponentially fast, with rates $\tau_T = \text{Im} \xi(0)|^{-1}$ and $\tau_D = \text{Im} \xi(\Delta)|^{-1}$, respectively. In particular, coherence of the initial state stays preserved on time scales of the order $\lambda^{-2}[|c|^2 \xi(\Delta) + (b - a)^2 \xi(0)]^{-1}$, c.f. (10).

IV. DISCUSSION

Relation (4) gives a detailed picture of the dynamics of averages of observables. The resonance energies $\varepsilon$ and the functionals $R_c$ can be calculated for concrete models, to arbitrary precision (in the sense of rigorous perturbation theory in $\lambda$). See (8)-(10) for explicit expressions for the qubit, and the illustration above for an initially coherent superposition given by (11). In the present work we use relation (4) to discuss the processes of thermalization and decoherence of a qubit. In [18] we present,
Besides a proof of (4), applications to energy-preserving (non-demolition) interactions and to registers of arbitrarily many qubits. It would be interesting to apply the techniques developed here to the analysis of the transition from quantum to classical behaviour (see [1, 22]).

In the absence of interaction (λ = 0) we have ε = ℂ ∈ R, see (5). Depending on the interaction each resonance energy ε may migrate into the upper complex plane, or it may stay on the real axis, as λ ≠ 0. The averages ⟨A⟩t approach their ergodic means ⟨⟨A⟩⟩∞ if and only if Im ε > 0 for all ε ≠ 0. In this case the convergence takes place on the time scale |Im ε|−1. Otherwise ⟨A⟩t oscillates. A sufficient condition for decay is that Im ε(s) < 0 (and λ small, see (5)).

There are two kinds of processes which drive the decay: energy-exchange processes and energy preserving ones. The former are induced by interactions enabling processes of absorption and emission of field quanta with energies corresponding to the Bohr frequencies of S (this is the “Fermi Golden Rule Condition” [9, 13, 15, 19, 20]). Energy preserving interactions suppress such processes, allowing only for a phase change of the system during the evolution (“phase damping”, [1–6, 21]).

Even if the initial density matrix, ρi=0, is a product of the system and reservoir density matrices, the density matrix, ρt, at any subsequent moment of time t > 0 is not of the product form. The evolution creates the system-reservoir entanglement. We develop a formula for ⟨A⟩t = ⟨⟨A⟩⟩∞ for all observables A of any N-level system S in [18]. If the system has the property of return to equilibrium, i.e., if ξ(Δ) > 0, then

]\[3]\[m,n] = δ_{m,n} \frac{e^{-\epsilon E_m}}{\sum_j e^{-\epsilon E_j}} + O(\lambda^2). \]

Hence the Gibbs distribution is obtained by first letting t → ∞ and then λ → 0. A similar observation in the setting of the quantum Langevin equation has been made in [24]. If ρ0 is an arbitrary initial density matrix on H_S ⊗ H_R then our method yields a similar result, see [18].

Equations (8), (9) and (10) define the decoherence time scale, \[\tau_D = |\text{Im} \varepsilon(\lambda)|^{-1}\], and the thermalization time scale, \[\tau_T = |\text{Im} \varepsilon_0(\lambda)|^{-1}\]. We should compare \[\tau_D\] with the decoherence time scales and with computational time scales in real systems. The former vary from 10⁴ s for nuclear spins in paramagnetic atoms to 10⁻¹² s for electron-hole excitations in bulk semiconductors (see e.g. [25]).

In the ubiquitous spin-boson model [26], obtained as a two-state truncation of a double-well system or an atom interacting with a Bose field, the Hamiltonian is given by (1) with \[H_S = -\frac{g}{2} \Delta \sigma_x + \frac{1}{2} \hbar \Delta \sigma_z\] and \[v = \sigma_z \otimes \varphi(g)\]. Here, \[\sigma_z, \sigma_x\] are Pauli spin matrices, \[\epsilon\] is the “bias” of the asymmetric double well, and \[\Delta\] is the “bare tunneling matrix element”. In the canonical basis, whose vectors represent the states of the system localized in the left and the right well, \[H_S\] has the representation

\[H_S = \frac{1}{2} \begin{bmatrix} \epsilon & -\hbar \Delta_0 \\ -\hbar \Delta_0 & -\epsilon \end{bmatrix}. \]

The diagonalization of \[H_S\] yields \[H_S \cong \text{diag}(E_+, E_-)\], where \[E_\pm = \pm \frac{1}{2} \sqrt{\epsilon^2 + 4 \hbar^2 \Delta_0^2}\]. The operator \[v = \sigma_z \otimes \varphi(g)\] is represented in the basis diagonalizing \[H_S\] as (6), with \[a = -b = -\left(\frac{\hbar^2 \Delta_0^2}{\epsilon^2} + 1\right)^{-1/2}\] and \[c = \frac{1}{2} \left(\frac{\epsilon^2}{\hbar^2 \Delta_0^2} + 1\right)^{-1/2}\].
