Abstract
The decomposition of polynomial spaces on unions of Grassmannians $G_{k_1,d} \cup \ldots \cup G_{k_r,d}$ into irreducible orthogonally invariant subspaces and their reproducing kernels are investigated. We also generalize the concepts of cubature points and $t$-designs from single Grassmannians to unions. We derive their characterization as minimizers of a suitable energy potential to enable $t$-design constructions by numerical optimization. We also present new analytic families of $t$-designs for $t = 1, 2, 3$.

1 Introduction

Polynomial approximation from samples on manifolds and homogeneous spaces has already been extensively studied, cf. [18,22,28,37] and references therein. Constituting distinct sampling rules, the concepts of cubatures and designs have also been widely investigated, cf. [20,24,25,32,36,40,41], where polynomials are integrated exactly by
a finite sum over the sampling values. However, many open questions remain when dealing with polynomials on unions of nonconnected manifolds.

Orthogonal projectors with fixed rank are used in many applications for analysis and dimension reduction purposes, cf. [31,44], leading to a function approximation problem on a single Grassmannian manifold. Projections with varying target dimensions are more flexible and may offer a larger range of applications. Therefore, we shall study unions of Grassmannians.

By studying the structure of polynomial spaces on the union of Grassmannians, some of our findings generalize results in [34]. In particular, we shall verify that the multiplicities of the irreducible representations of the orthogonal group occurring in an orthogonally invariant reproducing kernel Hilbert space on unions of Grassmannians coincide with the ranks of the kernel’s Fourier coefficients. This enables us to actually determine the multiplicities in the space of polynomials of degree \( t \). Moreover, we construct the underlying reproducing kernels for the irreducible components. While cubatures and \( t \)-designs in single Grassmannians have been studied in [2–5], we shall also investigate these concepts in unions of Grassmannians. We derive a characterization as minimizers of an energy functional induced by a reproducing kernel. By numerically minimizing the energy functional, we compute candidates for \( t \)-designs, i.e., \( t \)-designs up to machine precision. We are then able to describe these candidates analytically and check that the energy functional is minimized exactly.

It should be mentioned that the topic shares some common themes with Euclidean designs, cf. [40], where unions of spheres with varying radii in Euclidean space are considered, see also [7–10]. The structure of the polynomial spaces on unions of spheres have been investigated in [21], but the ideas in those proofs do not work for unions of Grassmannians, whose structure appears to be more involved.

The outline is as follows. In Sect. 2 we recall some facts on polynomial spaces on single Grassmannians and their irreducible decompositions. Section 3 is dedicated to some elementary results on polynomial spaces on unions of Grassmannians. Direct consequences of irreducible decompositions of polynomials on symmetric matrices are studied in Sect. 4. In Sect. 5 we determine the multiplicities of the polynomial spaces on unions and construct the underlying reproducing kernels for the irreducible components. In Sect. 6 we introduce cubatures and \( t \)-designs on unions of Grassmannians and derive a characterization as minimizers of an energy functional induced by a reproducing kernel. We compute some analytical minimizers in Sect. 7.

## 2 Polynomials on Single Grassmannians

This section is dedicated to summarizing some facts about single Grassmannians, see, for instance, [5,34]. The Grassmannian space of all \( k \)-dimensional linear subspaces of \( \mathbb{R}^d \) is naturally identified with the set of orthogonal projectors on \( \mathbb{R}^d \) of rank \( k \) denoted by

\[
G_{k,d} := \{ P \in \mathbb{R}^{d\times d}_{\text{sym}} : P^2 = P; \, \text{Tr}(P) = k \}.
\]
where $\mathbb{R}^{d \times d}_{\text{sym}}$ is the set of symmetric matrices in $\mathbb{R}^{d \times d}$. Each Grassmannian $\mathcal{G}_{k,d}$ admits a unique orthogonally invariant probability measure $\sigma_{k,d}$ induced by the Haar (probability) measure $\sigma_{\mathcal{O}(d)}$ on the orthogonal group $\mathcal{O}(d)$; i.e., for any $Q \in \mathcal{G}_{k,d}$ and measurable function $f$,

$$
\int_{\mathcal{G}_{k,d}} f(P) d\sigma_{k,d}(P) = \int_{\mathcal{O}(d)} f(QOQ^\top) d\sigma_{\mathcal{O}(d)}(O).
$$

The space of complex-valued, square-integrable functions $L^2(\mathcal{G}_{k,d})$, endowed with the inner product $(f, g)_{\mathcal{G}_{k,d}}$, decomposes into orthogonally invariant subspaces

$$
L^2(\mathcal{G}_{k,d}) = \bigoplus_{\ell(\lambda) \leq \min\{k, d-k\}} H_{\lambda}(\mathcal{G}_{k,d}), 
$$

where $H_{\lambda}(\mathcal{G}_{k,d})$ is equivalent to $\mathcal{H}_{2\lambda}^d$, the irreducible representation of $\mathcal{O}(d)$ associated with the partition $2\lambda = (2\lambda_1, \ldots, 2\lambda_t)$, cf. [5,34]. Note that two representations are equivalent if there is a linear isomorphism that commutes with the group action. A partition of $t$ is an integer vector $\lambda = (\lambda_1, \ldots, \lambda_t)$ with $\lambda_1 \geq \cdots \geq \lambda_t \geq 0$, $|\lambda| = t$, where $|\lambda| := \sum_{i=1}^{t} \lambda_i$, and the length $\ell(\lambda)$ is the number of nonzero parts of $\lambda$. Note that we add and suppress zero entries in $\lambda$ without further notice, so that we can also compare partitions of different lengths. For partitions $\lambda, \lambda'$ of integers $t, t'$, respectively, we write $\lambda \leq \lambda'$ if and only if $\lambda_i \leq \lambda'_i$ for all $i = 1, \ldots, \ell(\lambda)$.

The space of polynomials of degree at most $t$ on $\mathcal{G}_{k,d}$ is given by

$$
\text{Pol}_t(\mathcal{G}_{k,d}) := \{ f|_{\mathcal{G}_{k,d}} : f \in \mathbb{C}[X]_t \},
$$

where $\mathbb{C}[X]_t$ is the set of polynomials of degree at most $t$ in $d^2$ many variables arranged as a matrix $X \in \mathbb{C}^{d \times d}$, and $f|_{\mathcal{G}_{k,d}}$ denotes the restriction of $f$ to $\mathcal{G}_{k,d}$. This polynomial space decomposes into

$$
\text{Pol}_t(\mathcal{G}_{k,d}) = \bigoplus_{\ell(\lambda) \leq \min\{k, d-k\}} H_{\lambda}(\mathcal{G}_{k,d}),
$$

so that its dimension is calculated by adding the dimensions of each of the occurring $\mathcal{H}_{2\lambda}^d$. The dimension of $\mathcal{H}_{2\lambda}^d$ is specified in [27, Formulas (24.29) and (24.41)].

### 3 Polynomials on Unions of Grassmannians

Given a nonempty set $\mathcal{I} \subset \{1, \ldots, d-1\}$, the corresponding union of Grassmannians is

$$
\mathcal{G}_{\mathcal{I},d} := \bigcup_{k \in \mathcal{I}} \mathcal{G}_{k,d} = \{ P \in \mathbb{R}^{d \times d}_{\text{sym}} : P^2 = P, \ Tr(P) \in \mathcal{I} \}, \quad \mathcal{G}_d := \bigcup_{k=1}^{d-1} \mathcal{G}_{k,d}.
$$
An orthogonally invariant measure on $G_{I,d}$ is derived by the sum of the corresponding measures on the single Grassmannians. In Sect. 6, we shall also allow for weighted sums. According to (1), the corresponding space of complex-valued, square-integrable functions $L^2(G_{I,d})$ decomposes into

$$L^2(G_{I,d}) = \bigoplus_{\lambda \in \Lambda^d_I} H_\lambda(G_{I,d}), \quad H_\lambda(G_{I,d}) \cong |\mathcal{I}|^d \mathcal{H}^d_{2\lambda}, \quad (2)$$

where $\Lambda^d_I$ is the set of all partitions $\lambda$ of length at most $\max_{k \in I}(\min(k, d - k))$ and the multiplicities are the cardinality of

$$\mathcal{I}_\lambda^d := \{ k \in I : \ell(\lambda) \leq \min(k, d - k) \}.$$

As for a single Grassmannian, we consider polynomials on $G_{I,d}$ given by multivariate polynomials in the matrix entries of a given projector $P \in G_{I,d}$, i.e.,

$$\text{Pol}_t(G_{I,d}) := \{ f|G_{I,d} : f \in \mathbb{C}[X], t \text{ min} \}$$.  

This space decomposes orthogonally into

$$\text{Pol}_t(G_{I,d}) = \bigoplus_{|\lambda| \leq t, \lambda \in \Lambda^d_I} H_\lambda^d(G_{I,d}), \quad H_\lambda^d(G_{I,d}) \cong \mu^d_\lambda(I, t) \mathcal{H}^d_{2\lambda},$$

where the multiplicities $\mu^d_\lambda(I, t)$ still need to be determined. Indeed, this is the topic of the first part of the present paper.

**Theorem 3.1** For $t \geq 0$ and $I = [k_i]_{i=1}^r \subset \{1, \ldots, d-1\}$ with $r = |I|$, the multiplicity of $\mathcal{H}^d_{2\lambda}$ in the direct sum $\bigoplus_{i=1}^r \text{Pol}_{t-i+1}(G_{k_i,d})$ is a lower bound for that in $\text{Pol}_t(G_{I,d})$, where $s := \min(t + 1, |I|)$.

**Proof** The cases $t = 0$ and $|I| = 1$ are trivially fulfilled. Suppose $t \geq 1$ and $r \geq 2$. The restriction mapping $|G_{k_i,d} : \text{Pol}_t(G_{I,d}) \to \text{Pol}_{t}(G_{k_i,d})$ is orthogonally invariant and surjective, so that $\text{Pol}_t(G_{I,d})$ is equivalent to $\text{Pol}_{t}(G_{k_1,d}) \oplus \text{null}(\mid_{G_{k_1,d}})$. Let $\text{Tr}(\cdot)$ denote the trace. Since $(\text{Tr}(\cdot) - k_1) \text{Pol}_{t-1}(G_{I,d})$ is equivalent to $\text{Pol}_{t-1}(G_{[k_2,\ldots,k_r],d})$ and

$$(\text{Tr}(\cdot) - k_1) \text{Pol}_{t-1}(G_{I,d}) \subset \text{null}(\mid_{G_{k_1,d}}),$$

the number of irreducible components $\mathcal{H}^d_{2\lambda}$ in $\text{Pol}_t(G_{I,d})$ is bigger than or equals the respective number in $\text{Pol}_{t}(G_{k_1,d}) \oplus \text{Pol}_{t-1}(G_{[k_2,\ldots,k_r],d})$. An induction over $t$ and $r$ completes the proof. \hfill $\square$

If we order $I = [k_i]_{i=1}^r$ by $\min\{k_1, d-k_1\} \geq \cdots \geq \min\{k_r, d-k_r\}$, then counting the actual occurrences of $\mathcal{H}^d_{2\lambda}$ in $\bigoplus_{i=1}^r \text{Pol}_{t-i+1}(G_{k_i,d})$ yields the following explicit lower bound.
Corollary 3.2 For \( t \geq 0 \) and \( \mathcal{I} \subset \{1, \ldots, d-1\} \), the multiplicities \( \mu^d_\lambda(\mathcal{I}, t) \) satisfy

\[
\mu^d_\lambda(\mathcal{I}, t) \geq \min\{t - |\lambda| + 1, |\mathcal{I}^d\lambda|\}, \quad 0 \leq |\lambda| \leq t, \quad \lambda \in \Lambda^d_\mathcal{I}.
\]  

Reformulation yields \( \mu^d_\lambda(\mathcal{I}, |\lambda| + s) \geq \min\{s + 1, |\mathcal{I}^d\lambda|\} \) for \( s \geq 0 \). Due to (2), the upper bound \( \mu^d_\lambda(\mathcal{I}, t) \leq |\mathcal{I}^d\lambda| \) holds. Subsequent sections shall reveal that equality holds in (3). However, this requires a closer look at relations among irreducible representations and their reproducing kernels; see Appendix A.1 for some basics on reproducing kernels that shall be used in the following.

4 Determining the Multiplicities for a Few Special Cases

The space of polynomials on \( \mathbb{R}^{d \times d}_{\text{sym}} \) of degree at most \( t \) and its subspace of homogeneous polynomials of degree \( t \) are denoted by

\[
\text{Pol}_t(\mathbb{R}^{d \times d}_{\text{sym}}) := \{ f | \mathbb{R}^{d \times d}_{\text{sym}} : f \in \mathbb{C}[X] \},
\]

\[
\text{Hom}_t(\mathbb{R}^{d \times d}_{\text{sym}}) := \{ f \in \text{Pol}_t(\mathbb{R}^{d \times d}_{\text{sym}}) : f(\alpha X) = \alpha^t f(X), \ \alpha \in \mathbb{R}, \ X \in \mathbb{R}^{d \times d}_{\text{sym}} \},
\]

respectively. The differential inner product between \( f, g \in \text{Pol}_t(\mathbb{R}^{d \times d}_{\text{sym}}) \) given by

\[
(f, g)_D := f(D)g(0), \quad \text{where } D := \left( \frac{1}{2} (1 + \delta_{i,j}) \partial_{i,j} \right)_{i,j=1,\ldots,d}
\]

is orthogonally invariant, cf. [43], inducing the orthogonal decomposition

\[
\text{Pol}_t(\mathbb{R}^{d \times d}_{\text{sym}}) = \bigoplus_{s=0}^t \text{Hom}_s(\mathbb{R}^{d \times d}_{\text{sym}}).
\]

Remark 4.1 In accordance with [30], the mapping \((X, Y) \mapsto \frac{1}{3!} \text{Tr}(XY)^3\) is the reproducing kernel for \( \text{Hom}_3(\mathbb{R}^{d \times d}_{\text{sym}}) \) with respect to the differentiation inner product, cf. also Appendix A.1.

Let \( \text{GL}(d) \) denote the general linear group. The space \( \text{Hom}_t(\mathbb{R}^{d \times d}_{\text{sym}}) \) decomposes orthogonally into subspaces \( F_\lambda(\mathbb{R}^{d \times d}_{\text{sym}}) \) invariant under the action \( f \mapsto f(L \cdot L^\top) \), for \( L \in \text{GL}(d) \), by

\[
\text{Hom}_t(\mathbb{R}^{d \times d}_{\text{sym}}) = \bigoplus_{|\lambda|=t} F_\lambda(\mathbb{R}^{d \times d}_{\text{sym}}), \quad F_\lambda(\mathbb{R}^{d \times d}_{\text{sym}}) \cong F^d_{2\lambda},
\]

where \( F^d_{2\lambda} \) is the irreducible representation of \( \text{GL}(d) \) associated with \( 2\lambda = (2\lambda_1, \ldots, 2\lambda_t) \), cf. [30].
Remark 4.2 One can check that the function \((X, Y) \mapsto \frac{1}{|X!|} C_\lambda(XY)\) is the reproducing kernel for \(F_\lambda(\mathbb{R}^{d \times d}_{\text{sym}})\) with respect to the differentiation inner product, where \(C_\lambda\) is the zonal polynomial of index \(\lambda\), cf. [30] and Appendix B.1.

By restricting the group action from \(\text{GL}(d)\) to \(\mathcal{O}(d)\), the space \(F_\lambda(\mathbb{R}^{d \times d}_{\text{sym}})\) decomposes further as

\[
F_\lambda(\mathbb{R}^{d \times d}_{\text{sym}}) \cong \mathcal{F}^d_{2\lambda} \cong \bigoplus_{\ell' \leq 2\lambda} v^d_{2\lambda, \ell'}, \quad \ell(\lambda) \leq d, \tag{5}
\]

where the multiplicities \(v^d_{2\lambda, \ell'} \in \mathbb{N}_0\) are determined by the corresponding branching rule, cf. [26,33,35]. If \(\lambda'\) is such that \(\mathcal{H}^d_{\lambda'}\) is not defined, then we simply put \(v^d_{2\lambda, \lambda'} = 0\). We note that

\[
v^d_{2\lambda, (0)} = 1 \quad \text{for} \quad \ell(\lambda) \leq d, \quad v^d_{2\lambda, 2\lambda} = 1 \quad \text{for} \quad \ell(\lambda) \leq d/2.
\]

Thus, we obtain \(\mu^d_{\lambda}(\mathcal{I}, t) = 1\), for \(|\lambda| = t \geq 0\) with \(\lambda \in \Lambda^d_{\mathcal{I}}\). The latter enables us to verify that the lower bounds in Corollary 3.2 are an equality for \(|\mathcal{I}| = 2\). Indeed, if we order \(\mathcal{I} = \{k_1, k_2\} \subset \{1, \ldots, d-1\}\) by \(\min\{k_1, d-k_1\} \geq \min\{k_2, d-k_2\}\), then Theorem 3.1 and \(\mu^d_{\lambda}(\mathcal{I}, t) = 1\) imply

\[
\mu^d_{\lambda}([k_1, k_2], t) = \begin{cases} 1, & |\lambda| = t \text{ with } \ell(\lambda) \leq \min\{k_1, d-k_1\}, \\ 1, & |\lambda| \leq t - 1 \text{ with } \min\{k_2, d-k_2\} < \ell(\lambda) \leq \min\{k_1, d-k_1\}, \\ 2, & |\lambda| \leq t - 1 \text{ with } \ell(\lambda) \leq \min\{k_2, d-k_2\}, \end{cases}
\]

which means that equality holds in (3).

For arbitrary \(\mathcal{I} \subset \{1, \ldots, d-1\}\), we can still use (5) to determine the multiplicities \(\mu^d_{\lambda}(\mathcal{I}, t)\) provided that \(t\) is sufficiently small, but this takes some preparation. The space of homogeneous polynomials restricted to \(G_{\mathcal{I}, d}\) is denoted by \(\text{Hom}_t(G_{\mathcal{I}, d}) := \{f|G_{\mathcal{I}, d} : f \in \text{Hom}_t(\mathbb{R}^{d \times d}_{\text{sym}})\}\). It is important to notice that the restriction of \(\text{Hom}_t(\mathbb{R}^{d \times d}_{\text{sym}})\) to \(G_{\mathcal{I}, d}\) yields (almost) the entire space \(\text{Pol}_t(G_{\mathcal{I}, d})\):

Theorem 4.3 For \(t \geq 0\) and \(\mathcal{I} \subset \{1, \ldots, d-1\}\), the polynomial space decomposes into

\[
\text{Pol}_t(G_{\mathcal{I}, d}) = \begin{cases} \text{Hom}_t(G_{\mathcal{I}, d}) \oplus \text{Hom}_0(G_{\mathcal{I}, d}), & 1 \leq t \leq |\mathcal{I}| - 1, \\ \text{Hom}_t(G_{\mathcal{I}, d}), & \text{else}. \end{cases}
\]

Proof First we note that \(\text{Tr}(X)Y^t, X \in \mathbb{R}^{d \times d}_{\text{sym}}, \text{linearly generates the space Hom}_t(G_{\mathcal{I}, d}), \text{cf. Remark 4.1, (27), and (28)}\). Now, for \(t \geq 1\) and \(\mathcal{I} \subset \{1, \ldots, d-1\}\), we have

\[
\text{Tr}(XP)^s = \text{Tr}(XP)^{s-1} \text{Tr}(XP^{t-s+1}), \quad X \in \mathbb{R}^{d \times d}_{\text{sym}}, \quad P \in G_{\mathcal{I}, d}, \quad 1 \leq s \leq t.
\]
Since the term on the right-hand side is a homogeneous polynomial of degree $t$ in $P$ restricted to $\mathcal{G}_{\mathcal{I},d}$, we deduce

$$\text{Hom}_t(\mathcal{G}_{\mathcal{I},d}) = \{ f|_{\mathcal{G}_{\mathcal{I},d}} : f \in \text{Hom}_s(\mathbb{R}^{d \times d}_{\text{sym}}), \ s = 1, \ldots, t \}. \tag{6}$$

Thus, it remains to check that $1|_{\mathcal{G}_{\mathcal{I},d}} \notin \text{Hom}_t(\mathcal{G}_{\mathcal{I},d})$ if and only if $1 \leq t \leq |\mathcal{I}|-1$. Since $1|_{\mathcal{G}_{\mathcal{I},d}}$ is orthogonally invariant, it is sufficient to consider the orthogonally invariant subspace of $\text{Hom}_t(\mathcal{G}_{\mathcal{I},d})$ denoted by $\text{Hom}_t^O(d)(\mathcal{G}_{\mathcal{I},d})$. For $f \in \text{Hom}_t(\mathbb{R}^{d \times d}_{\text{sym}})$, we define

$$f_o(X) := \int_{\mathcal{O}(d)} f(OXO^\top)d\mu_{\mathcal{O}(d)}(O), \quad X \in \mathbb{R}^{d \times d},$$

so that $\text{Hom}_t^O(d)(\mathcal{G}_{\mathcal{I},d}) = \{ f_o|_{\mathcal{G}_{\mathcal{I},d}} : f \in \text{Hom}_t(\mathbb{R}^{d \times d}_{\text{sym}}) \}$. According to invariant theory, the ring of orthogonally invariant polynomials on $\mathbb{R}^{d \times d}_{\text{sym}}$ is generated by polynomials of the form $\text{Tr}(X^i)$, $X \in \mathbb{R}^{d \times d}_{\text{sym}}$, $i \in \mathbb{N}_0$, cf. [42, Theorem 7.1]. Since $f_o$ is also homogeneous of degree $t$,

$$f_o(X) = \sum_{l_1+\cdots+l_t=t} f_{l_1,\ldots,l_t} \prod_{i=1}^t \text{Tr}(X^{l_i}), \quad X \in \mathbb{R}^{d \times d}_{\text{sym}}.$$

For $t \geq 1$, the restriction $f_o|_{\mathcal{G}_{\mathcal{I},d}}$ is a linear combination of the functions $\text{Tr}((\cdot)^s)|_{\mathcal{G}_{\mathcal{I},d}}$, $s = 1, \ldots, t$. According to (6), these functions are contained in $\text{Hom}_t(\mathcal{G}_{\mathcal{I},d})$, so that $\text{Hom}_t^O(d)(\mathcal{G}_{\mathcal{I},d})$ is spanned by $\text{Tr}((\cdot)|_{\mathcal{G}_{\mathcal{I},d}}, \ldots, \text{Tr}((\cdot)^t)|_{\mathcal{G}_{\mathcal{I},d}}$, for $t \geq 1$. The invertibility of the Vandermonde matrix implies that $\text{Tr}(X^i)$ is generating for $X \in \mathbb{R}^{d \times d}_{\text{sym}}$, $i = 1, \ldots, t$, are linearly independent if and only if $1 \leq t \leq |\mathcal{I}|-1$. \hfill \square

**Remark 4.4** Fix some $t \geq 0$ and $\mathcal{I} \subset \{1, \ldots, d-1\}$. The map $(P, Q) \mapsto \text{Tr}(PQ)^t$ is a reproducing kernel for $\text{Hom}_t(\mathcal{G}_{\mathcal{I},d})$. For any constant $C > 0$, the map $(P, Q) \mapsto \text{Tr}(PQ)^t + C$ is a reproducing kernel for $\text{Pol}_t(\mathcal{G}_{\mathcal{I},d})$.

Next, we determine the multiplicities $\mu^d_\lambda(\mathcal{I}, t)$, for $t = 1, 2, 3$, by deriving upper bounds that match the lower bounds in Corollary 3.2. The decompositions (4) and (5) yield $\text{Hom}_1(\mathbb{R}^{d \times d}_{\text{sym}}) \cong \mathcal{H}^d_{(0)} \oplus \mathcal{H}^d_{(2)}$, for $d \geq 2$, and

$$\text{Hom}_2(\mathbb{R}^{d \times d}_{\text{sym}}) \cong \begin{cases} 2\mathcal{H}^d_{(0)} \oplus 2\mathcal{H}^d_{(2)} \oplus 2\mathcal{H}^d_{(4)} \oplus \mathcal{H}^d_{(2,2)}, & d \geq 4, \\ 2\mathcal{H}^d_{(0)} \oplus 2\mathcal{H}^d_{(2)} \oplus \mathcal{H}^d_{(4)}, & d = 3, \\ 2\mathcal{H}^d_{(0)} \oplus \mathcal{H}^d_{(2)} \oplus \mathcal{H}^d_{(4)}, & d = 2. \end{cases} \tag{7}$$

The multiplicities of $\mathcal{H}^d_\lambda$ in $\text{Hom}_t(\mathbb{R}^{d \times d}_{\text{sym}})$ are upper bounds for $\mu^d_\lambda(\mathcal{I}, t)$ since the restriction mapping is orthogonally invariant. For $t = 1, 2$, the lower bounds in Corollary 3.2 are matched, so that we have determined $\mu^d_\lambda(\mathcal{I}, 1)$ and $\mu^d_\lambda(\mathcal{I}, 2)$ for any index.
set $\mathcal{I} \subset \{1, \ldots, d - 1\}$. For $t = 3$, the analysis is more difficult, and we observe that the branching rules yield

\[
\text{Hom}_3(\mathbb{R}^{d \times d}_{\text{sym}}) \cong \begin{cases} 
3\mathcal{H}^d_{(0)} \oplus 4\mathcal{H}^d_{(2)} \oplus 2\mathcal{H}^d_{(4)} \oplus 2\mathcal{H}^d_{(2,2)} \oplus \mathcal{H}^d_{(3,1)} \oplus \mathcal{H}^d_{(6)} \oplus \mathcal{H}^d_{(4,2)} \oplus \mathcal{H}^d_{(2,2,2)}, & d \geq 6, \\
3\mathcal{H}^d_{(0)} \oplus 4\mathcal{H}^d_{(2)} \oplus 2\mathcal{H}^d_{(4)} \oplus 2\mathcal{H}^d_{(2,2)} \oplus \mathcal{H}^d_{(3,1)} \oplus \mathcal{H}^d_{(6)} \oplus \mathcal{H}^d_{(4,2)}, & d = 5, \\
3\mathcal{H}^d_{(0)} \oplus 3\mathcal{H}^d_{(2)} \oplus 2\mathcal{H}^d_{(4)} \oplus \mathcal{H}^d_{(3,1)} \oplus \mathcal{H}^d_{(6)} \oplus \mathcal{H}^d_{(4,2)}, & d = 4, \\
2\mathcal{H}^d_{(0)} \oplus 2\mathcal{H}^d_{(2)} \oplus \mathcal{H}^d_{(4)} \oplus \mathcal{H}^d_{(6)}, & d = 3,
\end{cases}
\]

The multiplicity of $\mathcal{H}^d_{(2)}$ in $\text{Hom}_3(\mathbb{R}^{d \times d}_{\text{sym}})$ does not match the lower bound in Corollary 3.2. Instead, we found that the kernel

\[
K(X, Y) = \frac{1}{d + 2} \left( \text{Tr}(X^2 Y^2) \text{Tr}(XY) - \text{Tr}(X^2 Y) \text{Tr}(XY^2) \right) \\
- \frac{1}{(3d + 4)(d + 2)} \left( \text{Tr}(X^2 Y^2) \text{Tr}(X) \text{Tr}(Y) - \text{Tr}(X^2 Y) \text{Tr}(X) \text{Tr}(Y^2) \\
- \text{Tr}(X Y^2) \text{Tr}(X^2 Y) + \text{Tr}(XY) \text{Tr}(X^2 Y^2) \right),
\]

which may not have been observed in the literature yet, reproduces a subspace of $\text{Hom}_3(\mathbb{R}^{d \times d}_{\text{sym}})$ equivalent to $\mathcal{H}^d_{(3,1)} \oplus \mathcal{H}^d_{(2)}$, for $d > 2$, and equivalent to $\mathcal{H}^d_{(2)}$, for $d = 2$, respectively. Since $K$ vanishes on any Grassmannian, i.e., $K(X, Y) = 0$, for all $Y \in \mathcal{G}_{k,d}$, $k \in \{1, \ldots, d - 1\}$ and $X \in \mathbb{R}^{d \times d}$, we deduce that the multiplicity of $\mathcal{H}^d_{(2)}$ in $\text{Pol}_3(\mathcal{G}_{\mathcal{I},d})$ is less than in $\text{Hom}_3(\mathbb{R}^{d \times d}_{\text{sym}})$. Now, for even partitions, the resulting upper bounds on the multiplicities match the lower bounds in Corollary 3.2 for $t = 3$ and any index set $\mathcal{I} \subset \{1, \ldots, d - 1\}$.

To determine the multiplicities of the irreducible subspaces of $\text{Pol}_3(\mathcal{G}_{\mathcal{I},d})$ for $|\mathcal{I}| \geq 3$, we used the reproducing kernel $K$ in (8). We shall further explore the reproducing kernels of the irreducible components to determine the multiplicities in $\text{Pol}_t(\mathcal{G}_{\mathcal{I},d})$ for $|\mathcal{I}| \geq 3$ and $t \geq 4$.

### 5 Zonal Kernels and Harmonic Analysis on Unions of Grassmannians

For $\ell(\lambda) \leq \min(k, d - k, l, d - l)$, the spaces $H_{\lambda}(\mathcal{G}_{k,d})$ and $H_{\lambda}(\mathcal{G}_{l,d})$ are equivalent; hence, there is a real intertwining isomorphism $T^{k,l}_{\lambda} : H_{\lambda}(\mathcal{G}_{k,d}) \to H_{\lambda}(\mathcal{G}_{l,d})$. In particular, $T^{k,l}_{\lambda}$ commutes with complex conjugation and the group action. It can be realized by an integral transform with a unique real-valued zonal function $p^{k,l}_{\lambda} : \mathcal{G}_{k,d} \times \mathcal{G}_{l,d} \to \mathbb{R}$, so that

\[
T^{k,l}_{\lambda} f = \int_{\mathcal{G}_{k,d}} p^{k,l}_{\lambda}(P, \cdot) f(P) d\sigma_{k,d}(P).
\]
Note that zonal means $p^{k,l}_\lambda (OPO^\top, OQO^\top) = p^{k,l}_\lambda (P, Q)$, for $O \in \mathcal{O}(d)$ and $P \in \mathcal{G}_{k,d}, \, Q \in \mathcal{G}_{l,d}$. For fixed $1 \leq k \leq l \leq \frac{d}{2}$ and $\ell(\lambda) \leq k$, the intertwining functions $p^{k,l}_\lambda$ were studied in [34] and expanded into the zonal polynomials by

$$p^{k,l}_\lambda (P, Q) = b^{k,l,d}_\lambda \sum_{\lambda' \leq \lambda} c^{d}_{\lambda,\lambda'} q^{(k)}_{\lambda,\lambda'} (\frac{1}{2}) q^{(\frac{1}{2})}_{\lambda,\lambda'} C^{(\frac{1}{2})}_\lambda (P Q),$$

for $\ell(\lambda) \leq k$, \, $1 \leq k \leq l \leq \frac{d}{2}$, \hspace{1cm} (10)

where $b^{k,l,d}_\lambda \in \mathbb{R}$ is a scaling constant, $c^{d}_{\lambda,\lambda'} = 1$, and $q^{(k)}_{\lambda,\lambda'}$ is a polynomial of degree $|\lambda| - |\lambda'|$ given by

$$q^{(k)}_{\lambda,\lambda'} (x) := \prod_{i=1}^{m} (x - \frac{1}{2} (i - 1) + \lambda'_i - \lambda_i) = \frac{(x)_{\lambda'}}{(x)_{\lambda}}, \hspace{0.5cm} x \in \mathbb{R}.$$

Potential zeros in the denominator of $\frac{(x)_{\lambda'}}{(x)_{\lambda}}$ cancel out, so that the fraction is well defined. Up to the scaling, which we have not specified yet, the functions $p^{k,k}_\lambda$ are the reproducing kernels for $H_\lambda (\mathcal{G}_{k,d})$ with respect to the $L^2$ inner product when $1 \leq k \leq d/2$ and $\ell(\lambda) \leq k$, cf. [34].

The sum of the right-hand side in (10) is still well defined for all $k, \, l \in \{1, \ldots, d-1\}$ and $\ell(\lambda) \leq \min(k, d-k, l, d-l)$. One of our contributions going beyond [34] is to determine the reproducing kernel of $H_\lambda^{[k]} (\mathcal{G}_d)$ with the help of a particular extension of (10) to this broader range of parameters. Recall that $\mathcal{G}_d = \bigcup_{k=1}^{d-1} \mathcal{G}_{k,d}$.

**Theorem 5.1** Let $\ell(\lambda) \leq d/2$. The reproducing kernel of $H_\lambda^{[k]} (\mathcal{G}_d)$ with respect to the $L^2$ inner product is a multiple of

$$p_\lambda (P, Q) := \sum_{\lambda' \leq \lambda} c^{d}_{\lambda,\lambda'} q^{(k)}_{\lambda,\lambda'} (\frac{1}{2} \text{Tr}(P)) q^{(\frac{1}{2})}_{\lambda,\lambda'} (\frac{1}{2} \text{Tr}(Q)) C^{(\frac{1}{2})}_\lambda (P Q), \hspace{0.5cm} P, \, Q \in \mathcal{G}_d.$$

In order to verify Theorem 5.1, we choose a suitable normalization of the intertwining functions, induced by the following selection of intertwining operators.

**Proposition 5.2** For all $k, \, l \in \{1, \ldots, d-1\}$ and $\ell(\lambda) \leq \min(k, d-k, l, d-l)$, there are real isometric isomorph intertwining operators $T^{k,l}_\lambda : H_\lambda (\mathcal{G}_{k,d}) \rightarrow H_\lambda (\mathcal{G}_{l,d})$ such that the following diagram commutes:

$$\begin{array}{ccc}
H_\lambda (\mathcal{G}_{k,d}) & \xrightarrow{T^{k,m}_\lambda} & H_\lambda (\mathcal{G}_{m,d}) \\
\downarrow T^{k,l}_\lambda & & \downarrow T^{m,l}_\lambda \\
H_\lambda (\mathcal{G}_{l,d}) & & H_\lambda (\mathcal{G}_{l,d})
\end{array}$$

for all $k, \, m, \, l \in \{\ell(\lambda), \ldots, d - \ell(\lambda)\}$.

**Proof** Let us fix an index $s$ with $\ell(\lambda) \leq s \leq d - \ell(\lambda)$. There are real isometric isomorph operators $\tilde{T}^{k,s}_\lambda, \, k \in \{\ell(\lambda), \ldots, \ell(\lambda)\}$, which intertwine the spaces $H_\lambda (\mathcal{G}_{k,d})$ and $H_\lambda (\mathcal{G}_{s,d})$. We now define
Fourier coefficients are

\[ T^{k,l}_\lambda := (\hat{T}^{l,s}_\lambda)^* \hat{T}^{k,s}_\lambda, \quad \ell(\lambda) \leq k, l \leq d - \ell(\lambda), \]

and straightforward calculations yield the statement. \hfill \Box

The integral operators in Proposition 5.2 induce intertwining functions \( p^{k,l}_\lambda \) via (9) satisfying

\[
\dim(H^d_{2\lambda}) = \int_{G_{k,d}} \int_{G_{l,d}} |p^{k,l}_\lambda(P, Q)|^2 d\sigma_{l,d}(Q) d\sigma_{k,d}(P), \\
p^{k,l}_\lambda(P, Q) = (p^{k,m}_\lambda(P, \cdot), p^{m,l}_\lambda(\cdot, Q))_{G_{m,d}} \quad \text{for} \ m \in \{\ell(\lambda), \ldots, d - \ell(\lambda)\}.  
\]

Remark 5.3 The intertwining functions \( p^{k,k}_\lambda \) are the reproducing kernels of \( H_\lambda(G_{k,d}) \cong H^d_{2\lambda} \) with respect to the standard \( L^2 \) inner product for \( k \in \{1, \ldots, d - 1\} \) and \( \ell(\lambda) \leq \min(k, d - k) \).

Let \( P^{k,l}_\lambda : G_{\mathcal{I},d} \times G_{\mathcal{I},d} \to \mathbb{R} \) denote the zero extension of \( p^{k,l}_\lambda \). It follows from [34] that the collection of zonal functions \( \{P^{k,l}_\lambda : \lambda \in \Lambda^d_2; k, l \in \mathcal{I}_d^d\} \) is an orthogonal basis for \( L^2_{O(d)}(G_{\mathcal{I},d} \times G_{\mathcal{I},d}) \), the space of square integrable functions that are zonal. Hence, any zonal function \( f \in L^2_{O(d)}(G_{\mathcal{I},d} \times G_{\mathcal{I},d}) \) can be expanded into a Fourier series; i.e.,

\[
f = \sum_{\lambda \in \Lambda^d_2} \sum_{k,l \in \mathcal{I}_d^d} \hat{f}^{k,l}_\lambda P^{k,l}_\lambda = \sum_{\lambda \in \Lambda^d_2} \text{Tr}(\hat{f}^{T}_\lambda P_\lambda),
\]

where the Fourier coefficients \( \hat{f}^{k,l}_\lambda \) and the basis functions \( P^{k,l}_\lambda \) are arranged in matrix form

\[
\hat{f}_\lambda := (\hat{f}^{k,l}_\lambda)_{k,l \in \mathcal{I}_d^d} \in \mathbb{C}^{\mathcal{I}_d^d \times \mathcal{I}_d^d}, \quad P_\lambda := (P^{k,l}_\lambda)_{k,l \in \mathcal{I}_d^d}.
\]

Convolving two continuous zonal functions \( f, g \in L^2_{O(d)}(G_{\mathcal{I},d} \times G_{\mathcal{I},d}) \),

\[
(f * g)(P, Q) := \left(f(P, \cdot), \overline{g(\cdot, Q)}\right)_{G_{\mathcal{I},d}} = \int_{G_{k,d}} f(P, R) g(R, Q) d\sigma_{k,d}(R),
\]

yields again a continuous zonal function \( f * g \). It is straightforward to check that its Fourier coefficients are \( \langle f * g \rangle_\lambda = \hat{f}_\lambda \hat{g}_\lambda \in \mathbb{C}^{\mathcal{I}_d^d \times \mathcal{I}_d^d}, \lambda \in \Lambda^d_2 \).

Remark 5.4 This convolution property implies that the kernel \((P, Q) \mapsto \text{Tr}(P_\lambda(P, Q))\), for \( \lambda \in \Lambda^d_2 \), is the reproducing kernel of \( H_\lambda(G_{\mathcal{I},d}) \) with respect to the \( L^2(G_{\mathcal{I},d}) \) inner product.

The Fourier coefficients \( \hat{K}_\lambda \in \mathbb{C}^{\mathcal{I}_d^d \times \mathcal{I}_d^d} \) of a positive definite zonal kernel \( K \in L^2_{O(d)}(G_{\mathcal{I},d} \times G_{\mathcal{I},d}) \) are positive semidefinite matrices and thus allow for a spectral decomposition

\( \hat{K}_\lambda \).
Theorem 5.5

Let $K$ be a zonal and positive definite. Under the notation of (14) and (15), we obtain $\mathcal{H}_d^2(\mathbb{I}_d) \cong S(K^i) \subset H_{\lambda}(\mathbb{G}_{\mathbb{I}_d})$, for each $i = 1, \ldots, |T^d_\lambda|$, and the multiplicity of $\mathcal{H}_d^2(\mathbb{I}_d)$ in $S(K)$ equals the rank of the Fourier coefficient $\hat{K}_\lambda$, implying the orthogonal decomposition

$$S(K) = \bigoplus_{\lambda \in \Lambda^d_{T}} \bigoplus_{i=1}^{\text{rank}(\hat{K}_\lambda)} S(K^i_\lambda).$$

(16)

Proof Mercer’s theorem implies that the reproducing kernel Hilbert space $S(K)$ decomposes into the pairwise orthogonal eigenspaces with nonzero eigenvalues associated with the integral operator $T_K : L^2(\mathbb{G}_{\mathbb{I}_d}) \to L^2(\mathbb{G}_{\mathbb{I}_d})$ defined by $T_K f(P) := (f, K(P, \cdot))_{\mathbb{G}_{\mathbb{I}_d}}$, $P \in \mathbb{G}_{\mathbb{I}_d}$, $f \in L^2(\mathbb{G}_{\mathbb{I}_d})$. This decomposition corresponds to the eigenspace decomposition of $T_K$ in the subspace $H_{\lambda}(\mathbb{G}_{\mathbb{I}_d})$. More precisely, the convolution property yields that the kernels $K^i_\lambda$ satisfy, for $i, j = 1, \ldots, |T^d_\lambda|$,\n
$$(T_K K^i_\lambda(P, \cdot))(Q) = a^i_\lambda K^j_\lambda(P, Q),$$

$$(K^i_\lambda(P, \cdot), K^j_\lambda(Q, \cdot))_{\mathbb{G}_{\mathbb{I}_d}} = \delta_{i,j} K^i_\lambda(P, Q),$$

$P, Q \in \mathbb{G}_{\mathbb{I}_d}$.

Hence, $K^i_\lambda$ are the reproducing kernels for the pairwise orthogonal spaces $S(K^i_\lambda)$ with respect to the standard inner product. The convolution property (12) yields that $\text{Tr}(XP_\lambda(P, \cdot)) \in H_{\lambda}(\mathbb{G}_{\mathbb{I}_d})$, for any matrix $X \in \mathbb{C}^{|T^d_\lambda| \times |T^d_\lambda|}$. Thus, we infer $S(K^i_\lambda) \subset H_{\lambda}(\mathbb{G}_{\mathbb{I}_d})$, so that

$$\bigoplus_{i=1}^{|T^d_\lambda|} S(K^i_\lambda) \subset H_{\lambda}(\mathbb{G}_{\mathbb{I}_d}) \cong |T^d_\lambda| \mathcal{H}_d^2(\mathbb{I}_d), \quad |\lambda| \geq 0.$$

Since the spaces $S(K^i_\lambda) \neq \{0\}$, $i = 1, \ldots, |T^d_\lambda|$, are orthogonally invariant and pairwise orthogonal, we obtain $S(K^i_\lambda) \cong \mathcal{H}_d^2(\mathbb{I}_d)$, which yields (16). □
Let \( K_{2\lambda} : \mathbb{R}^{d \times d}_{\text{sym}} \times \mathbb{R}^{d \times d}_{\text{sym}} \to \mathbb{R} \) denote the reproducing kernel with respect to the differentiation inner product of the irreducible representation \( H^d_{2\lambda} \) in \( \text{Hom}_{\mathcal{H}_d}((\mathbb{R}^{d \times d}_{\text{sym}})' \mathbb{R}^{d \times d}_{\text{sym}}) \). One of the ingredients for the following proof of Theorem 5.1 is that the restriction \( K_{2\lambda}|_{\mathcal{G}_{k,d} \times \mathcal{G}_{l,d}} \) coincides with \( p^{k,l}_{\lambda'} \) up to a multiplicative constant. Indeed, we shall follow the strategy in [34]:

**Proof of Theorem 5.1** Consider the positive definite zonal kernel

\[
K : \mathcal{G}_d \times \mathcal{G}_d \to \mathbb{R}, \quad K(P, Q) := C_{\lambda}(PQ), \quad P, Q \in \mathcal{G}_d.
\]

The relation (28) implies \( S(K) = F_{\lambda}(\mathbb{R}^{d \times d}_{\text{sym}})|_{\mathcal{G}_d} \). Theorem 5.5 and (5) yield

\[
K = \text{Tr}(\hat{K}^\top_{\lambda} P_{\lambda}) + \sum_{|\lambda'| < |\lambda|, \ell(\lambda') \leq \frac{d}{2}} \text{Tr}(\hat{K}^\top_{\lambda'} P_{\lambda'}).
\]

Furthermore, (5) implies that the irreducible representation \( H^d_{2\lambda} \) of \( O(d) \) occurs exactly once in \( S(K) \), so that Theorem 5.5 yields \( S(v_{\lambda}^\top P_{\lambda} v_{\lambda}) \simeq H^d_{|\lambda|}((\mathcal{I}, d)) \), where \( \hat{K}_{\lambda} = v_{\lambda}^\top v_{\lambda} \) for some nonzero vector \( v_{\lambda} \in \mathbb{R}^{\mathcal{I}_{\lambda}^d} \) with \( \mathcal{I} = \{1, \ldots, d - 1\} \). According to \( v_{\lambda}^\top P_{\lambda} v_{\lambda} = \text{Tr}(\hat{K}_{\lambda}^\top P_{\lambda}) \), we obtain

\[
v_{\lambda}^\top P_{\lambda}(P, Q) v_{\lambda} = C_{\lambda}(PQ) - \sum_{|\lambda'| < |\lambda|, \ell(\lambda') \leq \frac{d}{2}} \text{Tr}(\hat{K}_{\lambda'}^\top P_{\lambda'}(P, Q)), \quad P, Q \in \mathcal{G}_d.
\] \hspace{1cm} (17)

Note that \( v_{\lambda}^\top P_{\lambda} v_{\lambda} \) coincides up to a multiplicative factor with the restriction of the kernel \( K_{2\lambda} \). We shall verify in the following that the kernel \( v_{\lambda}^\top P_{\lambda} v_{\lambda} \) reflects the expansion of \( p_{\lambda} \) into zonal polynomials \( C_{\lambda'} \) defined in Theorem 5.1. Starting with (10), we exploit the vanishing and symmetry properties of the Jacobi polynomials, cf. Appendix B.3, combined with the symmetry relations of the intertwining functions, cf. Appendix B.2. We observe that, for any partition \( \lambda \) with \( \ell(\lambda) \leq \frac{d}{2} \) and any \( (P, Q) \in \mathcal{G}_{k,d} \times \mathcal{G}_{l,d} \) with \( 1 \leq k, l \leq d - 1 \),

\[
p_{\lambda}(P, Q) = \sum_{\lambda' \leq \lambda} c_{\lambda, \lambda'}^{d} q_{\lambda, \lambda'}(\frac{k}{2}) q_{\lambda, \lambda'}(\frac{l}{2}) C_{\lambda'}(PQ)
\] \hspace{1cm} (18)

where \( b_{\lambda, \lambda'}^{k, l, d} \in \mathbb{R} \setminus \{0\} \). After inserting the expansion from (18) into both sides of (17) via \( P_{\lambda} \) and \( P_{\lambda'} \), we aim to compare coefficients of the zonal polynomials. Let \( k, l \in \mathcal{I} = \{\ell(\lambda), \ldots, d - \ell(\lambda)\} \) be fixed. One can (only) show linear independence of the functions

\[
(P, Q) \mapsto C_{\lambda'}(PQ), \quad (P, Q) \in \mathcal{G}_{k,d} \times \mathcal{G}_{l,d}, \quad \ell(\lambda') \leq \min(k, d - k, l, d - l).
\]
Since $\lambda' \leq \lambda$ implies $\ell(\lambda') \leq \min(k, d - k, l, d - l)$, the zonal polynomials in (18) are linearly independent. By applying $P_{\lambda'}(P, Q) = 0$, $(P, Q) \in \mathcal{G}_{k,d} \times \mathcal{G}_{l,d}$, for $\ell(\lambda') > \min(k, d - k, l, d - l)$, the summation on the right-hand side in (17) reduces accordingly, and comparing coefficients is justified. Hence, we obtain $1 = v_{\lambda}^k v_{\lambda}^l b_{\lambda}^{k,l,d} c_{\lambda,\lambda}^d$, so that $c_{\lambda,\lambda}^d = 1$ leads to

$$p_{\lambda} |_{\mathcal{G}_{k,d} \times \mathcal{G}_{l,d}} = v_{\lambda}^k v_{\lambda}^l p_{\lambda}^{k,l}, \quad \ell(\lambda) \leq \min(k, d - k, l, d - l).$$

In other words, we have verified that, for $\ell(\lambda) \leq \text{Tr}(P), \text{Tr}(Q) \leq d - \ell(\lambda),$

$$v_{\lambda}^T P_{\lambda}(P, Q) v_{\lambda} = \sum_{\lambda' \leq \lambda} c_{\lambda,\lambda'}^d q_{\lambda,\lambda'}^d \left( \frac{1}{2} \text{Tr}(P) \right) q_{\lambda,\lambda'}^d \left( \frac{1}{2} \text{Tr}(Q) \right) C_{\lambda'}(PQ) = p_{\lambda}(P, Q).$$

(19)

For the remaining cases, we observe that $v_{\lambda}^T P_{\lambda}(P, Q) v_{\lambda} = 0$, and $p_{\lambda}(P, Q) = 0$ holds due to (18).

For $|\lambda| = 0, 1, 2$, we present the kernels $K_{2\lambda}$ and $p_{\lambda}$ as well as $p_{\lambda}^{k,l}$ and $v_{\lambda}^k$ in Appendix D. We now replace $P_{\lambda}$ with $p_{\lambda}$ and still have a suitable Fourier expansion:

**Corollary 5.6** For $\mathcal{I} \subset \{1, \ldots, d - 1\}$, let $K : \mathcal{G}_{\mathcal{I},d} \times \mathcal{G}_{\mathcal{I},d} \to \mathbb{C}$ be a positive definite zonal kernel. Then there is a unique symmetric function $\hat{K}_{\lambda} : \mathcal{I}_d \times \mathcal{I}_d \to \mathbb{C}$ such that

$$K(P, Q) = \sum_{\lambda \in \Lambda_d} \hat{K}_{\lambda}(\text{Tr}(P), \text{Tr}(Q)) p_{\lambda}(P, Q), \quad P, Q \in \mathcal{G}_{\mathcal{I},d},$$

and the multiplicity of $\mathcal{H}_{2\lambda}^d$ in $\mathcal{S}(K)$ is the rank of the matrix $(\hat{K}_{\lambda}(k, l))_{k,l \in \mathcal{I}_d}$.

**Proof** The Fourier expansion (13) with coefficients $\hat{K}_{\lambda}^{k,l}$ yields $\hat{K}_{\lambda}(k, l) = (v_{\lambda}^k)^{-1} \hat{K}_{\lambda}^{k,l} (v_{\lambda}^l)^{-1}$, where $v_{\lambda}$ is given in (19). Therefore, the rank of $\left( \hat{K}_{\lambda}(k, l) \right)_{k,l \in \mathcal{I}_d}$ is the same as the one of the original Fourier coefficient, so that Theorem 5.5 implies the statement.

The following result is an important step forward:

**Theorem 5.7** For $\mathcal{I} \subset \{1, \ldots, d - 1\}$ and any partition $\lambda$ with $\ell(\lambda) \leq \frac{d}{2}$ and $s = 0, \ldots, |\mathcal{I}_d| - 1$, the multiplicity of $\mathcal{H}_{2\lambda}^d$ in $H_{\lambda}^{|\lambda|+s} (\mathcal{G}_{d})$ is $s + 1$.

**Proof** For any partition $\lambda$ with $\ell(\lambda) \leq \frac{d}{2}$, and $i = 0, \ldots, |\mathcal{I}_d| - 1$, there are polynomials $q_{\lambda}^i : \mathbb{R} \to \mathbb{R}$ of degree $i$ satisfying the orthogonality relations

$$\sum_{m=\ell(\lambda)}^{d-\ell(\lambda)} q_{\lambda}^i(m) q_{\lambda}^j(m) |v_{\lambda}^m|^2 = \delta_{i,j}, \quad i, j = 0, \ldots, |\mathcal{I}_d| - 1.$$
where \( v_\lambda \) is given in (19). We can define the associated positive definite kernels \( K^i_\lambda : \mathcal{G}_d \times \mathcal{G}_d \to \mathbb{R} \) by

\[
K^i_\lambda(P, Q) := q^i_\lambda(P)q^l_\lambda(Q)p_\lambda(P, Q), \quad P, Q \in \mathcal{G}_d. \tag{20}
\]

For \( P \in \mathcal{G}_{k,d} \), \( Q \in \mathcal{G}_{l,d} \), the identity

\[
\int_{\mathcal{G}_{m,d}} p_\lambda(P) p_\lambda(R) d\sigma_{m,d}(R) = v^l_\lambda |v^m_\lambda|^2 v^l_\lambda \int_{\mathcal{G}_{m,d}} p^{k,m}_{\lambda}(P) p^{k,l}_{\lambda}(R) d\sigma_{m,d}(R)
\]

implies \( K^i_\lambda \ast K^j_\lambda = \delta_{i,j} K^j_\lambda \). Hence, Corollary 5.6 leads to

\[
\bigoplus_{i=0}^s S(K^i_\lambda) \subset H^{1\mid |\lambda|+s}_\lambda(\mathcal{G}_d), \quad s = 0, \ldots, |\mathcal{T}^d_\lambda| - 1. \tag{21}
\]

Note that (21) also implies the lower bound on the multiplicities in Corollary 3.2. We shall complete the proof in Appendix C, where we verify that (21) holds with equality; i.e., we decompose \( H^{1\mid |\lambda|+s}_\lambda(\mathcal{G}_d) \) into \( s+1 \) orthogonal subspaces of increasing polynomial degree with simple multiplicities.

We are now able to determine the multiplicities of the irreducible components in \( \text{Pol}_t(\mathcal{G}_{\mathcal{I},d}) \).

**Theorem 5.8** For \( \mathcal{I} \subset \{1, \ldots, d-1\} \) and \( t \geq 0 \), the following holds:

\[
\mu^d_\lambda(\mathcal{I}, t) = \begin{cases} 
\min\{t - |\lambda| + 1, |\mathcal{T}^d_\lambda|\}, & 0 \leq |\lambda| \leq t, \quad \lambda \in \Lambda^d_{\mathcal{I}}, \\
0, & \text{else}.
\end{cases}
\]

**Proof** According to Corollary 3.2, we only need to suitably bound \( \mu^d_\lambda(\mathcal{I}, t) \) from above. Proposition 5.7 yields \( \mu^d_\lambda(\{1, \ldots, d-1\}, t) \leq t - |\lambda| + 1 \). Since \( \mu^d_\lambda(\mathcal{I}, t) \leq \mu^d_\lambda(\{1, \ldots, d-1\}, t) \) and the general upper bound \( \mu^d_\lambda(\mathcal{I}, t) \leq |\mathcal{T}^d_\lambda| \) holds, we conclude the proof. \( \square \)

The knowledge of \( \dim(\mathcal{H}^d_{\mathcal{I},\lambda}) \) through [27, Formulas (24.29) and (24.41)] enables us to compute the dimension of \( \text{Pol}_t(\mathcal{G}_{\mathcal{I},d}) \). Moreover, counting irreducible components yields

\[
\text{Pol}_t(\mathcal{G}_{\mathcal{I},d}) \cong \bigoplus_{i=1}^s \text{Pol}_{t-i+1}(\mathcal{G}_{k_i,d}), \quad s := \min\{t + 1, |\mathcal{I}|\}, \tag{22}
\]

where \( \mathcal{I} = \{k_i\}_{i=1}^r \) is ordered such that \( \min\{k_1, d-k_1\} \geq \cdots \geq \min\{k_r, d-k_r\} \), so that equality actually holds in Theorem 3.1. Our proof of Theorem 3.1 then reveals the intriguing identity

\[
\text{null}(|\mathcal{G}_{k_1,d}|) = (\text{Tr}(\cdot) - k_1) \text{Pol}_{t-1}(\mathcal{G}_{\mathcal{I},d}), \quad t \geq 1, \tag{23}
\]

\( \square \) Springer
with the restriction mapping $|G_{k_1,d}| : \text{Pol}_t(G_{I,d}) \rightarrow \text{Pol}_t(G_{k_1,d})$.

6 Cubatures and Designs on Unions of Grassmannians

So far, we have analyzed the irreducible decomposition of polynomial spaces on unions of Grassmannians. Our results enable us in the following to study cubatures on unions of Grassmannians.

6.1 Introducing Cubatures and Designs

Any orthogonally invariant finite signed measure $\sigma_{I,d}$ on $G_{I,d}$ is a linear combination of the Haar (probability) measures $\sigma_{k,d}$, $k \in I$, i.e.,

$$\sigma_{I,d} = \sum_{k \in I} m_k \sigma_{k,d},$$

for some $\{m_k\}_{k \in I} \subset \mathbb{R}$. For points $\{(P_j, \omega_j)\}_{j=1}^n \subset G_{I,d}$ and weights $\{\omega_j\}_{j=1}^n \subset \mathbb{R}$, we say that $\{(P_j, \omega_j)\}_{j=1}^n$ is a cubature for $\text{Pol}_t(G_{I,d})$ (resp. $\text{Hom}_t(G_{I,d})$) with respect to $\sigma_{I,d}$ if

$$\int_{G_{I,d}} f(P)d\sigma_{I,d}(P) = \sum_{j=1}^n \omega_j f(P_j), \quad f \in \text{Pol}_t(G_{I,d}) \quad \text{(resp. } f \in \text{Hom}_t(G_{I,d})).$$

If $\{(P_j, \omega_j)\}_{j=1}^n$ is a cubature for $\text{Hom}_t(G_{I,d})$ with $\sum_{k \in I} m_k = \sum_{j=1}^n \omega_j$, then it is also a cubature for $\text{Pol}_t(G_{I,d})$, cf. Theorem 4.3. The value of the parameter $t$ is often called the strength of the cubature.

**Remark 6.1** According to [19, Propositions 2.6 and 2.7], there is a cubature $\{(P_j, \omega_j)\}_{j=1}^n$ with nonnegative weights $\{\omega_j\}_{j=1}^n$ for $\text{Pol}_t(G_{I,d})$ with respect to $\sigma_{I,d}$ such that $n \leq \dim(\text{Pol}_t(G_{I,d}))$. For $m_k \neq 0$, $k \in I$, any cubature $\{(P_j, \omega_j)\}_{j=1}^n$ for $\text{Pol}_2(G_{I,d})$ with respect to $\sigma_{I,d}$ with nonnegative weights satisfies $n \geq \dim(\text{Pol}_2(G_{I,d}))$, cf. [19, Proposition 1.7].

Analogously to Euclidean designs, cf. [7–10], cubatures on unions of Grassmannians induce cubatures on single Grassmannians, but potentially with lower strength:

**Proposition 6.2** If $\{(P_j, \omega_j)\}_{j=1}^n$ is a cubature for $\text{Pol}_t(G_{I,d})$, $t \geq |I| - 1$, with respect to the signed measure $\sigma_{I,d} = \sum_{k \in I} m_k \sigma_{k,d}$, then, for any $k \in I$,

$$\{(P_j, \omega_j) : P_j \in G_{k,d}, \quad j = 1, \ldots, n\}$$

is a cubature for $\text{Pol}_s(G_{k,d})$ with respect to the signed measure $m_k \sigma_{k,d}$, where $s = t - |I| + 1$. 
Proof} Let \( f \) be a polynomial of degree at most \( s \) on \( \mathbb{R}^{d \times d}_{\text{sym}} \); then we know that \( 1_{G_{k,d}} \cdot f \) is a polynomial of degree at most \( t \). Hence, the statement follows from

\[
m_k \int_{G_{k,d}} f(P) d\sigma_{k,d} = \int_{G_{I,d}} (1_{G_{k,d}} \cdot f)(P) d\sigma_{I,d} = \sum_{j : P_j \in G_{k,d}} \omega_j f(P_j). \tag*{\square}
\]

We also observe that any cubature of strength \( 2t \) gives rise to a cubature of strength \( 2t + 1 \):

**Proposition 6.3** Let \( \{(P_j, \omega_j)\}_{j=1}^n \) be a cubature for \( \text{Pol}_t(\mathcal{G}_{I,d}) \) with respect to the signed measure \( \sigma_{I,d} = \sum_{k \in I} m_k \sigma_{k,d} \). Then

\[
\{(P_j, \omega_j)\}_{j=1}^n \cup \{(I - P_j, (-1)^j \omega_j)\}_{j=1}^n
\]

is a cubature for \( \text{Pol}_{t+1}(\mathcal{G}_{I \cup (d-I),d}) \) with respect to the signed measure

\[
\sigma_{I \cup (d-I),d} = \sum_{k \in I} m_k (\sigma_{k,d} + (-1)^j \sigma_{d-k,d}).
\]

**Proof** In view of Remark 4.4, it is sufficient to consider the polynomial \( \text{Tr}(X \cdot)^{t+1} |_{\mathcal{G}_{I \cup (d-I),d}} \) for \( X \in \mathbb{R}^{d \times d}_{\text{sym}} \). Then we have

\[
\int_{\mathcal{G}_{I \cup (d-I),d}} \text{Tr}(XP)^{t+1} d\sigma_{I \cup (d-I),d}(P) = \int_{\mathcal{G}_{I,d}} \text{Tr}(XP)^{t+1} d\sigma_{I,d}(P)
\]

\[
+ \int_{\mathcal{G}_{I,d}} \text{Tr}(X(I - P))^{t+1}(-1)^j d\sigma_{I,d}(P)
\]

\[
= \int_{\mathcal{G}_{I,d}} \left( \text{Tr}(XP)^{t+1} + (-1)^j \text{Tr}(X(I - P))^{t+1} \right) d\sigma_{I,d}(P).
\]

The mapping \( P \mapsto \text{Tr}(XP)^{t+1} + (-1)^j \text{Tr}(X(I - P))^{t+1} \) is contained in \( \text{Pol}_t(\mathcal{G}_{I,d}) \), because the two terms with exponent \( t + 1 \) cancel out. Thus, \( \{(P_j, \omega_j)\}_{j=1}^n \) being a cubature for \( \text{Pol}_t(\mathcal{G}_{I,d}) \) yields

\[
\int_{\mathcal{G}_{I \cup (d-I),d}} \text{Tr}(XP)^{t+1} d\sigma_{I \cup (d-I),d}(P)
\]

\[
= \sum_{j=1}^n \omega_j \left( \text{Tr}(XP_j)^{t+1} + (-1)^j \text{Tr}(X(I - P_j))^{t+1} \right). \tag*{\square}
\]

Cubatures of strength \( t \) on single Grassmannians, whose weights are all the same, are called \( t \)-designs and have been studied in \([2–5]\). We shall extend this concept to unions of Grassmannians after a brief observation on characteristic functions. For \( t = |I| - 1 \) with \( I = \{k_0, \ldots, k_t\} \), the Vandermonde matrix \( V = (k_i^j)_{i,j=0,\ldots,t} \in \mathbb{R}^{t+1} \) is invertible. Hence, for \( i = 0, \ldots, t \), there are \( \alpha_i := (\alpha_{i,0}, \ldots, \alpha_{i,t})^T \in \mathbb{R}^{t+1} \) with \( V\alpha_i = e_{i+1} \) implying

\[
\sum_{j=0}^t \alpha_{i,j} \text{Tr}(P)^j = \begin{cases} 1, & P \in G_{k_i,d}, \\ 0, & P \in \mathcal{G}_{I,d} \setminus G_{k_i,d}. \end{cases}
\]
Thus, the characteristic function of each $G_{k,d}$ is contained in $\text{Pol}_{t}(G_{\mathcal{I},d})$, for all $t \geq |\mathcal{I}| - 1$. The latter yields that any cubature $\{ (P_j, \omega_j) \}_{j=1}^{n}$ for $\text{Pol}_{t}(G_{\mathcal{I},d})$ with respect to $\sigma_{\mathcal{I},d} = \sum_{k \in \mathcal{I}} m_k \sigma_{k,d}$ satisfies $m_k = \sum_{j : P_j \in G_{k,d}} \omega_j$, for $k \in \mathcal{I}$. If weights are the same on each single $G_{k,d}$, then those weights must be $\frac{m_k}{n_k}$, where $n_k = |\{ j : P_j \in G_{k,d} \}|$. Indeed, we impose this condition in our definition of designs:

**Definition 6.4** Let $\mathcal{P}_k \subset G_{k,d}$ be finite, and set $n_k := |\mathcal{P}_k|$. The collection $\mathcal{P}_{\mathcal{I}} = \bigcup_{k \in \mathcal{I}} \mathcal{P}_k$, is called a $t$-design with respect to an orthogonally invariant signed measure $\sigma_{\mathcal{I},d} = \sum_{k \in \mathcal{I}} m_k \sigma_{k,d}$ if

$$\int_{G_{\mathcal{I},d}} f(P) \, d\sigma_{\mathcal{I},d}(P) = \sum_{k \in \mathcal{I}} \frac{m_k}{n_k} \sum_{P \in \mathcal{P}_k} f(P) \quad \text{for all } f \in \text{Pol}_{t}(G_{\mathcal{I},d}).$$

Thus, any $t$-design is a cubature, whose weights are the same on each Grassmannian but can differ across different Grassmannians. For $|\mathcal{I}| = 1$, our definition reduces to the standard Grassmannian designs as considered in [2–5]. The existence of $t$-designs with $t = 1$ in single Grassmannians was studied in [14]. For a discussion on the existence of 1-designs in unions of Grassmannians with $\frac{m_k}{n_k} = \frac{m_l}{n_l}$, for all $k, l \in \mathcal{I}$, we refer to [12].

### 6.2 Constructing Cubatures and Designs by Numerical Minimization

To construct cubatures or designs, we consider the $t$-fusion frame potential, cf. [6],

$$\text{FFP}_t((P_j, \omega_j))_{j=1}^{n} := \sum_{i,j=1}^{n} \omega_i \omega_j \text{Tr}(P_i P_j)^t,$$

where $\{ P_j \}_{j=1}^{n} \subset G_{\mathcal{I},d}$ and $\{ \omega_j \}_{j=1}^{n}$. The 1-fusion frame potential was already investigated in [13,38]. Lower bounds on the $t$-fusion frame potential for general positive integers $t$ were derived in [6]. Only for single Grassmannians, i.e., $|\mathcal{I}| = 1$, those $\{ (P_j, \omega_j) \}_{j=1}^{n}$ were characterized in [6], for which the bounds are matched. In the following, we provide a characterization for the general case $|\mathcal{I}| \geq 1$. Before we state this result though, it is convenient to define

$$T_{\sigma_{\mathcal{I},d}}(t) := \int_{G_{\mathcal{I},d}} \int_{G_{\mathcal{I},d}} \text{Tr}(PQ)^t \, d\sigma_{\mathcal{I},d}(P) \, d\sigma_{\mathcal{I},d}(Q) = m^\top T_{\mathcal{I},d}(t)m, \quad (24)$$

where $\sigma_{\mathcal{I},d} = \sum_{k \in \mathcal{I}} m_k \sigma_{k,d}$ and $m = (m_k)_{k \in \mathcal{I}}$ with the matrix $T_{\mathcal{I},d}(t) \in \mathbb{R}^{|\mathcal{I}| \times |\mathcal{I}|}$ being given by

$$(T_{\mathcal{I},d}(t))_{k,l} := \int_{G_{k,d}} \int_{G_{l,d}} \text{Tr}(PQ)^t \, d\sigma_{k,d}(P) \, d\sigma_{l,d}(Q).$$
Note that $T_{I,d}(t)$ is the $(0)$-th Fourier coefficient of the positive definite zonal kernel $K_t(P,Q) = \text{Tr}(PQ)^t$, for $P,Q \in \mathcal{G}_{I,d}$, and thus symmetric and positive semidefinite.

**Theorem 6.5** Given $\{P_j\}_{j=1}^n \subset \mathcal{G}_{I,d}$ with weights $\{\omega_j\}_{j=1}^n \subset \mathbb{R}$, let $m_k = \sum_{\{j:P_j \in \mathcal{G}_{k,d}\}} \omega_j$. Then the fusion frame potential is bounded from below by

$$\text{FFP}_t(\{(P_j, \omega_j)\}_{j=1}^n) \geq T_{\sigma_{I,d}}(t).$$

Equality holds if and only if $\{(P_j, \omega_j)\}_{j=1}^n$ is a cubature for $\text{Pol}_t(\mathcal{G}_{I,d})$ with respect to $\sigma_{I,d}$.

This theorem is an extension of results in [6], where the lower bound is already derived but equality is not discussed. For the proof, we refer to Appendix A.2.

Theorem 6.5 enables the use of numerical minimization schemes to derive cubatures. Knowledge of the global lower bound $T_{\sigma_{I,d}}(t)$ is important to check if numerical solutions are indeed cubatures by ruling out that the minimization got stuck in a local minimum. The matrix $T_{I,d}(t)$ can be computed via zonal polynomials by

$$T_{I,d}(t) = \sum_{|\lambda|=t, \ell(\lambda) \leq d/2} \frac{c_\lambda c_\lambda^T}{C_\lambda(I_d)} \in \mathbb{R}^{|\mathcal{I}| \times |\mathcal{I}|}, \quad c_\lambda := (C_\lambda(I_k))_{k \in \mathcal{I}} \in \mathbb{R}^{|\mathcal{I}|},$$

cf. (30) in Appendix B.1, and note that $C_\lambda(I_k)$ is explicitly computed in [15,30,39].

For suitable minimization algorithms on Grassmannians, we refer to [1,11,29]. In Sect. 7 we shall indeed numerically minimize the fusion frame potential with equal weights and check that the lower bound is attained.

**7 Examples of $t$-Designs Derived from Numerical Minimization**

Here, we shall construct some families of 1-, 2-, and 3-designs in unions of Grassmannians. By numerically minimizing the energy functional (25) using a conjugate gradient approach, cf. [29, Section 3.3.1], we compute candidates for $t$-designs, i.e., $t$-designs up to machine precision. Based on the special structures of the Gram matrices of these numerical minimizers, we looked for group orbits that describe them analytically. Indeed “beautifying” our numerical results, we were able to analytically specify our candidates, which turned out to be exact minimizers.

**7.1 A Family of 1-Designs in Arbitrary Dimensions**

We analytically construct $d$ lines and 1 hyperplane in $\mathbb{R}^d$, so that the corresponding orthogonal projectors are a 1-design in $\mathcal{G}_{1,d} \cup \mathcal{G}_{d-1,d}$ with respect to the measure $\sigma_{\{1,d-1\},d} = m_1\sigma_{1,d} + m_{d-1}\sigma_{d-1,d}$, with $m_1 = 1$ and $m_{d-1} \in [-1/(d-1), 1]$. Indeed, let the $d$ lines be described by the vectors
\[ a_i := \sqrt{1 - m_{d-1}} e_i + \frac{1}{d} (\sqrt{1 + (d - 1) m_{d-1}} - \sqrt{1 - m_{d-1}}) e \in \mathbb{R}^d, \quad i = 1, \ldots, d, \]

where \( e_i \in \mathbb{R}^d \) are the standard unit vectors and \( e := e_1 + \cdots + e_d \). The associated rank-1 projectors are \( P_i := a_i a_i^\top \in \mathbb{R}^d, i = 1, \ldots, d, \) and the rank-\( (d - 1) \) projector is \( P_{d+1} := I_d - \frac{1}{d} e e^\top \). We calculate

\[
T_{\sigma_{1,d}+m_{d-1}\sigma_{d-1,d}}(1) = \frac{1}{d} (1 + (d - 1) m_{d-1})^2
\]

and observe equality with the 1-fusion frame potential \( \text{FFP}_1\{((P_j, \omega_j)_{j=1}^{d+1})\} \) with weights \( \omega_1 = \cdots = \omega_d = \frac{m_1}{d}, \omega_{d+1} = m_{d-1} \). According to Theorem 6.5, \( \{(P_j, \omega_j)\}_{j=1}^{d+1} \) is a 1-design.

For \( m_{d-1} = 1 \), the \( d \) lines coincide and are orthogonal to the hyperplane. This configuration can also be considered as a single line with one hyperplane forming a 1-design. If \( -1/(d - 1) \leq m_{d-1} < 1 \), then this one line is split into \( d \) lines forming a \( (d - 1) \)-dimensional simplex, and, for \( m_{d-1} = -1/(d - 1) \), the lines lie in the hyperplane.

**Remark 7.1** According to Proposition 6.2, any cubature of strength 1 in \( G_{1,d} \cup G_{d-1,d} \) yields parts in \( G_{1,d} \) and in \( G_{d-1,d} \) that are cubatures of strength 0. Hence, there must be at least one element in each. For \( m_1 = m_{d-1} = 1 \), the above example matches this lower bound.

### 7.2 A Family of 1-Designs in \( \mathbb{R}^4 \)

We construct a family of 2 lines and 2 planes in \( \mathbb{R}^4 \) forming a 1-design with respect to \( m_1 \in [-2, 2] \) and \( m_2 = 1 \). The rank-1 projectors are \( P_1 := e_1 e_1^\top, P_2 := e_3 e_3^\top \in \mathbb{R}^4, \) and the 2-dimensional projectors are

\[
P_3 := \begin{pmatrix} a_3 a_3^\top & 0 \\ 0 & a_3 a_3^\top \end{pmatrix}, \quad P_4 := \begin{pmatrix} a_4 a_4^\top & 0 \\ 0 & a_4 a_4^\top \end{pmatrix} \in \mathbb{R}^4, \quad a_{3/4} := \frac{1}{2} \left( \frac{\sqrt{2 - m_1}}{\pm \sqrt{2 + m_1}} \right) \in \mathbb{R}^2.
\]

For \( m_1 \in [-2, 2] \), this family provides 1-designs since equality holds in Theorem 6.5, where \( T_{m_1\sigma_{1,4}+\sigma_{2,4}}(1) = \left( 1 + \frac{m_1}{2} \right)^2 \). For \( m_1 = 2 \), the two planes coincide and the two lines are orthogonal to each other and to the planes. The two planes also coincide for \( m_1 = -2 \), and then the two lines span the same plane. The choice \( m_1 = 0 \) yields two planes that are orthogonal to each other.

**Remark 7.2** For \( m_1, m_2 > 0 \), there do not exist any 1-designs in \( G_{1,4} \cup G_{2,4} \) of cardinality 2. In this sense, our example with \( m_1 = 2 \) and \( m_2 = 1 \) is optimal.

### 7.3 A Family of 2-Designs in \( \mathbb{R}^3 \)

The numerical minimization enabled us to identify an analytic family of 6 lines and 4 planes in \( \mathbb{R}^3 \) forming a 2-design with \( m_1 = 1 \) and \( m_2 \in [-3/8, 3/2] \). The tetrahedral
We shall provide a family of 8 lines and 8 planes in $\mathbb{R}^4$ generated by a cyclic coordinate shift $R_1 = e_2e_1^T + e_3e_2^T + e_1e_3^T \in \mathbb{R}^{3 \times 3}$ and a reflection $R_2 = I_4 - 2e_1e_1^T$. The 6 lines and 4 planes are obtained as distinct orbits under the canonical action of the tetrahedral group. The rank-1 and rank-2 projectors are

$$\mathcal{P}_1 := \{RP_1\bar{R}^T : R \in T\}, \quad P_1 := \frac{1}{2}a_1a_1^T, \quad a_1 := \left(\sqrt{1 - v}, \sqrt{1 + v}, 0\right)^T,$$

$$\mathcal{P}_2 := \{RP_2\bar{R}^T : R \in T\}, \quad P_2 := I - \frac{1}{3}e_1e_1^T \in \mathbb{R}^3,$$

respectively, where $v := \frac{1}{13}(3 + 8m_2)$. For $m_2 \in [-3/8, 3/2]$, the union $\mathcal{P} = \mathcal{P}_1 \cup \mathcal{P}_2$ is a 2-design since equality holds in Theorem 6.5 for $t = 2$ with $\mathcal{T}_{\sigma_1,3 + m_2 \sigma_2,3}(2) = \frac{1}{13}(3 + 16m_2 + 28m_2^2)$. For $m_2 = 3/2$, there are 4 planes, and the 6 lines collapse to the 3 coordinate axes. If $m_2 = -3/8$, then the 6 lines are exactly the 6 intersection lines of the 4 planes. For $m_2 = 0$, the 6 lines correspond to the vertices of the icosahedron.

**Remark 7.3** Any cubature of strength 2 with nonnegative weights needs at least $n$ distinct cubature points with $n \geq \dim(\text{Pol}_1(G_{1,3}))$, cf. Remark 6.1. Theorem 5.8 leads to $\dim(\text{Pol}_1(G_{1,3} \cup G_{2,3})) = 7$, so that our construction of 4 planes and 3 lines associated with the choice $m_1 = 1$ and $m_2 = 3/2$ has the minimal number of elements. Moreover, Proposition 6.2 implies that any 2-design on $G_{1,3} \cup G_{2,3}$ has at least 3 lines.

### 7.4 A Family of 2-Designs in $\mathbb{R}^4$

We shall provide a family of 8 lines and 8 planes in $\mathbb{R}^4$ forming a 2-design for $m_1 = 1$ and $m_2 \in [3/4, 3/2]$. The lines are generated by a symmetry group $G_1$ of cardinality $|G_1| = 64$, which is generated by a cyclic coordinate shift $R_1 = e_2e_1^T + e_3e_2^T + e_4e_3^T + e_1e_4^T \in \mathbb{R}^{4 \times 4}$ and reflection $R_2 = I_4 - 2e_1e_1^T$. The rank-1 projectors are the orbit

$$\mathcal{P}_1 := \{RP_1\bar{R}^T : R \in G_1\}, \quad P_1 := \frac{1}{2}a_1a_1^T, \quad a_1 := \left(\sqrt{1 - v}, \sqrt{1 + v}, 0, 0\right)^T,$$

where $v := \sqrt{5}(8m_2 - 3)$. The planes are derived from two orbits under a cyclic group $G_2$ of cardinality $|G_2| = 4$ generated by $R_3 = -e_3e_1^T + e_2e_2^T + e_1e_3^T - e_4e_4^T \in \mathbb{R}^{4 \times 4}$. More precisely, the set of rank-2 projectors is $\mathcal{P}_2 := \{RP_i\bar{R}^T : R \in G_2, \ i = 2, 3\}$ with

$$P_{2/3} := \frac{1}{6} \begin{pmatrix} 3 & \sqrt{2} - 3b^2 & \sqrt{2} + 3b^2 & \pm\sqrt{4 - b^2} & \mp\sqrt{2 + 3b^2 + b^4} \\ \sqrt{2} - 3b^2 & 3 & \sqrt{1 - b^2} & \sqrt{2} + 3b^2 & \pm\sqrt{4 - b^2} \\ \sqrt{2} + 3b^2 & \sqrt{2} + 3b^2 & 3 & \mp\sqrt{2 - 3b^2 + b^4} & \pm\sqrt{2 + 3b^2 + b^4} \\ \pm\sqrt{4 - b^2} & \pm\sqrt{4 - b^2} & \pm\sqrt{2 - 3b^2 + b^4} & 3 & \mp\sqrt{1 - b^2} \\ \mp\sqrt{2 + 3b^2 + b^4} & \mp\sqrt{2 + 3b^2 + b^4} & \pm\sqrt{2 + 3b^2 + b^4} & \pm\sqrt{2 - 3b^2 + b^4} & 3 \pm\sqrt{1 - b^2} \end{pmatrix}.$$
where \( b := \sqrt{2 - \frac{3}{2m_2}} \). For \( \mathcal{P} := \mathcal{P}_1 \cup \mathcal{P}_2 \), the lower bound \( T_{\sigma_1,4+m_2\sigma_2,4}(2) = \frac{1}{72} (9 + 48m_2 + 80m_2^2) \) on the 2-fusion frame potential is matched for \( m_2 \in [3/4, 3/2] \). Therefore, \( \mathcal{P} \) is indeed a 2-design. For \( m_2 = 3/2 \), each plane intersects two other planes in one line, and the 8 lines coincide in pairs with the 4 coordinate axes.

**Remark 7.4** Proposition 6.2 yields that any 2-designs with \( d = 4 \), \( m_1 = 1 \), and \( m_2 = 3/2 \) must have at least 4 lines, which is matched by our example of 4 lines and 8 planes.

### 7.5 A 2-Design in \( \mathbb{R}^5 \)

The following collection of 5 lines and 16 planes in \( \mathbb{R}^5 \) forms a 2-design for \( m_1 = 1 \) and \( m_2 = 5/3 \). The lines are given by the 5 coordinate axes, i.e., \( \mathcal{P}_1 := \{ P_i : i = 1, \ldots, 5 \} \), \( P_i := e_i e_i^\top \in \mathbb{R}^{5 \times 5} \), for \( i = 1, \ldots, 5 \). To construct the planes, we consider the transformation group \( G \) of cardinality \( |G| = 16 \), generated by \( G_1 = I_3 - e_5 e_5^\top + e_4 e_4^\top \in \mathbb{R}^{5 \times 5} \) and \( G_2 = e_2 e_2^\top - e_1 e_1^\top + e_3 e_3^\top + e_4 e_4^\top - e_5 e_5^\top \). The set of rank-2 projectors is the orbit \( \mathcal{P}_2 := \{ RP_6 R^\top: R \in G \} \), where

\[
P_6 := \frac{1}{5} \begin{pmatrix}
2 & \sqrt{\frac{2}{3}} & \sqrt{\frac{1}{6}(9+5\sqrt{3})} & \frac{1}{6}(3-5\sqrt{3}) & \sqrt{\frac{2}{3}} \\
\sqrt{\frac{3}{2}} & 2 & \sqrt{\frac{1}{6}(9-5\sqrt{3})} & \frac{2}{3} & \frac{1}{6}(3+5\sqrt{3}) \\
\sqrt{\frac{1}{6}(9+5\sqrt{3})} & \sqrt{\frac{3}{2}} & 2 & -\sqrt{\frac{1}{6}(9+5\sqrt{3})} & -\sqrt{\frac{1}{6}(9-5\sqrt{3})} \\
\frac{1}{6}(3-5\sqrt{3}) & \sqrt{\frac{3}{2}} & -\sqrt{\frac{1}{6}(9+5\sqrt{3})} & 2 & \sqrt{\frac{2}{3}} \\
\sqrt{\frac{3}{2}} & \frac{1}{6}(3+5\sqrt{3}) & -\sqrt{\frac{1}{6}(9-5\sqrt{3})} & \frac{2}{3} & 2 \\
\end{pmatrix}
\]

For \( \mathcal{P} := \mathcal{P}_1 \cup \mathcal{P}_2 \), the lower bound \( T_{\sigma_1,5+m_2\sigma_2,5}(2) = \frac{131}{45} \) on the 2-fusion frame potential is matched, so that \( \mathcal{P} \) is indeed a 2-design.

**Remark 7.5** Similarly to the previous example, Proposition 6.2 yields that any 2-design with \( d = 5 \), \( m_1 = 1 \), and \( m_2 = 5/3 \) must have at least 5 lines, which is matched.

### 7.6 From 2t-Designs to 2t + 1-Designs

Theorem 6.3 yields a construction of \( 2t + 1 \)-designs from \( 2t \)-designs. Hence, any \( 2t \)-design in the Sects. 7.3, 7.4, and 7.5 gives rise to a \( 3 \)-design. For instance, the 6 lines going through the vertices of the icosahedron are a 2-design in \( \mathbb{R}^3 \). By adding the 6 complementary planes, we obtain a 3-design with respect to \( m_1 = m_2 = 1 \).

**Remark 7.6** Proposition 6.2 yields that the parts in each single Grassmannian \( G_{k,d} \) of a 3-design for \( G_{I_3,d} \) with \( |I| = 2 \) must be a cubature of strength 2. Any such cubature must have at least 6 elements for \( d = 3 \), so that our 3-design with 12 elements in the union of two Grassmannians is optimal.

Appendix A. Reproducing Kernels

A.1 Some Basics on Reproducing Kernels

A Hilbert space $\mathcal{H}(X)$ of continuous functions on a set $X \subset \mathbb{R}^d$ with inner product $(f, g)_{\mathcal{H}(X)}$, for $f, g \in \mathcal{H}(X)$, is called a reproducing kernel Hilbert space if point evaluation is continuous. For such a Hilbert space, there exists a unique (continuous) positive definite kernel $K : X \times X \to \mathbb{C}$, i.e., $K(x, y) = \overline{K(y, x)}$, for $x, y \in X$, and

$$0 \leq \sum_{i,j=1}^{M} c_i \overline{c_j} K(x_i, x_j), \quad \text{for all } x_i \in X, \ c_i \in \mathbb{C}, \ i = 1, \ldots, M, \ M \in \mathbb{N},$$

such that $K(x, \cdot) \in \mathcal{H}(X)$, $x \in X$, and the reproducing property

$$f(x) = (f, K(x, \cdot))_{\mathcal{H}(X)}, \quad f \in \mathcal{H}(X), \ x \in X, \quad (26)$$

holds.

Conversely, any continuous positive definite kernel $K : X \times X \to \mathbb{C}$ gives rise to a unique reproducing kernel Hilbert space $\mathcal{S}(K)$ of continuous functions, so that the function space

$$\mathcal{S}^0(K) := \text{span}\{K(x, \cdot) : x \in X\} \quad (27)$$

is dense in $\mathcal{S}(K)$ and $K$ satisfies the reproducing property. Here, we exclusively deal with polynomial kernels $K$ so that $m := \dim(\mathcal{S}^0(K)) < \infty$, and a basis of $\mathcal{S}(K) = \mathcal{S}^0(K)$ is given by the functions $K(x_i, \cdot) : X \to \mathbb{C}$, for $i = 1, \ldots, m$, if the matrix

$$(K(x_i, x_j))_{i,j=1}^{m} \in \mathbb{C}^{m \times m}$$

is invertible. The reproducing property (26) is satisfied with respect to the inner product

$$(f, g)_{\mathcal{S}(K)} := \sum_{i,j=1}^{m} \alpha_i \overline{\beta_j} K(x_i, x_j),$$
where \( f = \sum_{i=1}^{m} \alpha_i K(x_i, \cdot) \) and \( g = \sum_{i=1}^{m} \beta_i K(x_i, \cdot) \). It turns out that the restrictions \( S(K)|_Y \) to compact subsets \( Y \subset X \) are generated by the restricted kernel itself; i.e., if \( Y \subset X \) is compact, then
\[
S(K)|_Y = S(K|_{Y \times Y}),
\]
see also [45, Theorem 10.47] for a more general setting. For more details on the theory of reproducing kernel Hilbert spaces, we refer to [45].

### A.2 Proof of Theorem 6.5

For the sake of completeness, we provide the proof of Theorem 6.5.

**Proof** The worst-case cubature error \( E_t \) in the reproducing kernel Hilbert space \( S(K_t) = \text{Hom}_t(G_{I,d}) \) with reproducing kernel \( K_t(P, Q) = \text{Tr}(PQ)^t \), for \( P, Q \in G_{I,d} \), is defined by
\[
E_t([^n_{j=1}(P_j, \omega_j)]_{j=1}, \sigma_{I,d}) := \sup_{f \in \text{Hom}_t(G_{I,d}), \|f\|_{K_t}=1} \left| \int_{G_{I,d}} f(P)d\sigma_{I,d}(P) - \sum_{j=1}^{n} \omega_j f(P_j) \right|,
\]
where \( \| \cdot \|_{K_t} \) is the norm in \( \text{Hom}_t(G_{I,d}) \) induced by \( K_t \). The squared worst-case cubature error satisfies
\[
E_t^2([^n_{j=1}(P_j, \omega_j)]_{j=1}, \sigma_{I,d}) = \sum_{i,j=1}^{n} \omega_i \omega_j \text{Tr}(P_i P_j)^t - 2 \sum_{i=1}^{n} \omega_i \int_{G_{K,d}} \text{Tr}(P_i Q)^t d\sigma_{I,d}(Q)
\]
\[
+ \int_{G_{K,d}} \int_{G_{I,d}} \text{Tr}(P Q)^t d\sigma_{I,d}(P)d\sigma_{I,d}(Q),
\]
cf. [29, Theorem 2.7]. Isolating the \( t \)-fusion frame potential and noting that the conditions on \( m_k \) imply \( \sum_{i=1}^{n} \omega_i \int_{G_{K,d}} K_t(P_i, Q)d\sigma_{I,d}(Q) = T_{\sigma_{I,d}}(t) \) yields the lower bound. The expression in (29) equals 0 if and only if \( ([P_j, \omega_j])_{j=1}^{n} \) is a cubature for \( \text{Hom}_t(G_{I,d}) \) with respect to \( \sigma_{I,d} \).

**Appendix B. Properties of Special Polynomials**

### B.1 Zonal Polynomials

The zonal polynomial \( C_\lambda \) is an orthogonally invariant homogeneous polynomial of degree \( |\lambda| \) on \( \mathbb{R}^{d \times d}_{\text{sym}} \), see [15,30,39]. It satisfies \( C_\lambda(X) = 0 \) if \( \text{rank}(X) < \ell(\lambda) \), and
\[
\int_{O} C_\lambda(X(YO)\top)d\sigma_{O(d)}(O) = \frac{C_\lambda(X)C_\lambda(Y)}{C_\lambda(I_d)}, \quad X, Y \in \mathbb{R}^{d \times d}_{\text{sym}}, \quad \ell(\lambda) \leq d.
\]
where $I_d$ is the identity matrix in $\mathbb{R}^d$. They are normalized such that $\text{Tr}(X)^t = \sum_{|\lambda|=t} C_\lambda(X)$, for $X \in \mathbb{R}^{d \times d}_{\text{sym}}$. The evaluation of zonal polynomials can be extended, so that $C_\lambda(XY)$ makes sense for $X, Y \in \mathbb{R}^{d \times d}_{\text{sym}}$, cf. [30]. The zonal polynomials do not depend on the dimension $d$ of the matrix argument, but only on the nonzero eigenvalues of the matrix, which explains the lack of an index $d$ in their notation.

### B.2 Intertwining Functions

Let $\lambda$ be a partition with $\ell(\lambda) \leq d/2$. For $P \in G_{k,d}$, $Q \in G_{l,d}$ with $\ell(\lambda) \leq k, l \leq d - \ell(\lambda)$, the intertwining functions $p_{\lambda}^{k,l}$ considered in Sect. 5, cf. (11) and (12), satisfy the symmetry relations

$$p_{\lambda}^{k,l}(P, Q) = p_{\lambda}^{l,k}(Q, P), \quad p_{\lambda}^{k,l}(P, Q) = \varepsilon_k p_{\lambda}^{d-k,l}(I - P, Q),$$

where the constant $\varepsilon_k \in \{\pm 1\}$ only depends on $k$. The latter is a consequence of $P \mapsto I - P$ inducing an intertwining operator.

### B.3 Jacobi Polynomials

In [34] the intertwining functions $p_{\lambda}^{k,l}$ are related to the generalized Jacobi polynomials $J_{\lambda}^{\ell, \frac{d}{2}}$ in $k$ variables only for the cases $1 \leq k \leq l \leq \frac{d}{2}, \ell(\lambda) \leq k$ via (10), where

$$J_{\lambda}^{\ell, \frac{d}{2}}(y_1(PQ), \ldots, y_k(PQ)) = \sum_{\lambda' \leq \lambda}^{d} c_{\lambda, \lambda', \frac{d}{2}} q_{\lambda, \lambda'}(\frac{\ell}{2}) C_{\lambda'}(PQ),$$

and $y_1(PQ) \geq \cdots \geq y_d(PQ)$ are the eigenvalues of the matrix $PQ$ (counted with multiplicities). In order to deal with general $k, l$, we define generalized Jacobi polynomials $J_{\lambda}^{\alpha, \beta} : \mathbb{R}^m \to \mathbb{R}$ beyond the usual parameter range $\frac{1}{2}(m-1) < \alpha < \beta - \frac{1}{2}(m-1)$ in [16,17,23,34]; i.e., we define, for any $\beta > \ell(\lambda) - 1$, $\alpha \in \mathbb{R}$, and $y_1, \ldots, y_m \in \mathbb{R}$, $m \in \mathbb{N}$,

$$J_{\lambda}^{\alpha, \beta}(y_1, \ldots, y_m) := \sum_{\lambda' \leq \lambda}^{c_{\lambda, \lambda', \alpha}} q_{\lambda, \lambda'}(\alpha) q_{\lambda, \lambda'}(\frac{m}{2}) C_{\lambda'}(\text{diag}(y_1, \ldots, y_m)). \quad (31)$$

The functions $q_{\lambda, \lambda'}$ are continuously and uniquely extended to $\mathbb{R}$. The coefficients $c_{\lambda, \lambda'}^{\beta}$ in (31) depend on $\lambda, \lambda', \beta$ in a rational way, due to the recursion formula in [23,34]. In particular, they are well-defined for $\beta > \ell(\lambda) - 1$.

Certain properties and symmetry relations of the generalized Jacobi polynomials in the usual parameter range are also valid in the extended parameter range. Indeed, let $\lambda$ be a partition satisfying $\beta > \ell(\lambda) - 1$, $\alpha \in \mathbb{R}$. For $m \in \mathbb{N}$, we have

$$J_{\lambda}^{\alpha, \beta}(y_1, \ldots, y_m) = (-1)^{\lambda} J_{\lambda}^{\beta - \alpha, \beta}(1 - y_1, \ldots, 1 - y_m), \quad y_1, \ldots, y_m \in \mathbb{R}.\,$$

Springer
If $m < \ell(\lambda)$, then $J_{\lambda}^{\alpha,\beta}(y_1, \ldots, y_m) = 0$ holds. If $k, l \in \mathbb{N}$ with $l > k$, then we obtain

$$J_{\lambda}^{l-k}(y_1, \ldots, y_k) = \left( J_{\lambda}^{k}(y_1, \ldots, y_k, 0, \ldots, 0) \right)^{l-k\text{-times}}$$

$y_1, \ldots, y_k \in \mathbb{R}$.

### B.4 Even and Odd Kernels

The sets of even and odd functions on $G$ are denoted by

$$S_+ := \{ f \in L^2(G_d) \mid f = f(I - \cdot) \}, \quad S_- := \{ f \in L^2(G_d) \mid f = -f(I - \cdot) \},$$

respectively, and the orthogonal decomposition $L^2(G_d) = S_+ \oplus S_-$ holds.

We call positive definite zonal kernels $K_+$ and $K_-$ even and odd if they satisfy

$$K_+(P, Q) = K_+(I - P, Q), \quad K_-(P, Q) = -K_-(I - P, Q), \quad P, Q \in G_d,$$

respectively. The corresponding reproducing kernel Hilbert spaces $S(K_{\pm})$ contain only odd and even functions, respectively. If $K$ satisfies $K(P, Q) = K(I - P, I - Q)$, for $P, Q \in G_d$, then it can be uniquely decomposed into an even and odd part; i.e., $K = K_+ + K_-$ such that

$$S(K) = S(K_+) \oplus S(K_-), \quad S(K) \cap S_+ = S(K_+), \quad S(K) \cap S_- = S(K_-).$$

The kernel $K^s(P, Q) := 1 + 2\text{Tr}(PQ)^s + 2\text{Tr}((I - P)(I - Q))^s$, for $P, Q \in G_d$, linearly generates $\text{Pol}_s(G_d)$, cf. Remark 4.4. One observes that $K_{2t+1}^s(P, \cdot)$ is a polynomial of degree $2t$ and $K_{2t+2}^s(P, \cdot)$ is a polynomial of degree $2t + 1$, cf. the proof of Proposition 6.3. Therefore, we obtain

$$\text{Pol}_{2t+1}(G_d) \cap S_+ \subset \text{Pol}_{2t}(G_d), \quad \text{Pol}_{2t+2}(G_d) \cap S_- \subset \text{Pol}_{2t+1}(G_d). \quad (32)$$

Hence, since $H_{\lambda}^{[\lambda]}(G_d)$ has multiplicity one, its reproducing kernel $p_\lambda$ is an even or odd kernel, depending on $|\lambda|$; i.e., it satisfies the symmetry relations

$$p_\lambda(P, Q) = (-1)^{|\lambda|} p_\lambda(P, I - Q), \quad P, Q \in G_d, \quad \ell(\lambda) \leq d/2. \quad (33)$$

We shall verify that being even or odd transfers into symmetry conditions on the kernel’s coefficients when expanded in zonal polynomials.

**Lemma B.1** For any partition $\lambda$ with $\ell(\lambda) \leq \frac{d}{2}$, let $K : G_d \times G_d \to \mathbb{R}$ be a positive definite zonal kernel obeying $K(P, Q) = (-1)^t K(P, I - Q)$, for $P, Q \in G_d$, with some $t \geq |\lambda|$, and admitting the expansion

$$K(P, Q) = \sum_{|\lambda'| \leq t, \ell(\lambda') \leq d} r_{\lambda'}(\text{Tr}(P), \text{Tr}(Q))C_{\lambda'}(PQ), \quad P, Q \in G_d. \quad (34)$$
If $S(K) \subset H_{\lambda}(G_d)$, then, for $k \in \{\ell(\lambda), \ldots, \frac{d}{2}\}$ and $l \in \{\ell(\lambda), \ldots, d - \ell(\lambda)\}$,

$$r_\lambda(k, l) = (-1)^{l - |\lambda|} r_\lambda(k, d - l)$$  \hspace{1cm} (35)

holds.

The following proof is based on comparing coefficients in the expansion (34) after exploiting the binomial expansion of zonal polynomials.

**Proof** We know by Corollary 5.6 that the only nonzero Fourier coefficient of $K$ is $\tilde{K}_\lambda$. We now fix $k \in \mathcal{I} := \{\ell(\lambda), \ldots, \lfloor \frac{d}{2} \rfloor\}$. Comparing coefficients of $C_{\lambda'}(PQ)$ on $G_{k,d} \times G_{l,d}$, $l \in \mathcal{I}$ via (10) yields $r_{\lambda'}(k, l) = 0$, for $l \in \mathcal{I}$, $|\lambda'| > |\lambda|$, $\ell(\lambda') \leq k$. For $P \in G_{k,d}$, the orthogonal invariance and the binomial expansion of the zonal polynomials, cf. [15,23,39], yield

$$K(P, I - Q) = \sum_{|\lambda'| \leq t, \ell(\lambda') \leq k} r_{\lambda'}(\text{Tr}(P), d - \text{Tr}(Q)) C_{\lambda'}(P(I - Q))$$

$$= \sum_{|\lambda'| \leq t, \ell(\lambda') \leq k} r_{\lambda'}(\text{Tr}(P), d - \text{Tr}(Q))$$

$$\sum_{\lambda'' \leq \lambda'} \binom{\lambda'}{\lambda''} (-1)^{|\lambda''|} \frac{C_{\lambda''}(I_k)}{C_{\lambda'}(I_k)} C_{\lambda''}(PQ)$$

$$= \sum_{|\lambda''| \leq t, \ell(\lambda'') \leq k} \tilde{r}_{\lambda''}(\text{Tr}(P), \text{Tr}(Q)) C_{\lambda''}(PQ), \quad P, Q \in G_d,$$

where $\binom{\lambda'}{\lambda''}$ are generalized binomial coefficients, cf. [23], and, for $|\lambda''| \leq t$ with $\ell(\lambda'') \leq k$,

$$\tilde{r}_{\lambda''}(k, l) := \sum_{|\lambda'| \leq t, \lambda'' \leq \lambda', \ell(\lambda') \leq k} \binom{\lambda'}{\lambda''} (-1)^{|\lambda''|} \frac{C_{\lambda''}(I_k)}{C_{\lambda'}(I_k)} r_{\lambda'}(k, d - l), \quad l \in \{1, \ldots, d - 1\}. \hspace{1cm} (36)$$

According to the assumption $K(P, Q) = (-1)^t K(P, I - Q)$, we again compare coefficients and obtain $\tilde{r}_{\lambda''}(k, l) = 0$, for $l \in \mathcal{I}$, $|\lambda''| > |\lambda|$, $\ell(\lambda'') \leq k$. Note that $\binom{\lambda'}{\lambda''} = 1$ holds, cf. [23]. One can now show by induction using (36) and starting with $|\lambda''| = t$ that this implies $r_{\lambda''}(k, d - l) = 0$, $l \in \mathcal{I}$, $|\lambda''| > |\lambda|$, $\ell(\lambda'') \leq k$. By using the latter, for $P \in G_{k,d}$ and $Q \in G_{I,d}$, we arrive at the expansions

$$K(P, Q) = \sum_{|\lambda'| \leq |\lambda|, \ell(\lambda') \leq k} r_{\lambda'}(\text{Tr}(P), \text{Tr}(Q)) C_{\lambda'}(PQ),$$

$$K(P, I - Q) = \sum_{|\lambda''| = |\lambda|, \ell(\lambda'') \leq k} (-1)^{|\lambda''|} r_{\lambda''}(\text{Tr}(P), d - \text{Tr}(Q)) C_{\lambda''}(PQ)$$

$$+ \sum_{|\lambda''| < |\lambda|, \ell(\lambda'') \leq k} \tilde{r}_{\lambda''}(\text{Tr}(P), \text{Tr}(Q)) C_{\lambda''}(PQ).$$

\( \copyright \) Springer
According to $K(P, Q) = (-1)^{l} K(P, I - Q)$, the assertion (35) is derived by comparing coefficients again. □

Appendix C. Proof of Theorem 5.7

Let us complete the proof of Theorem 5.7 by verifying that (21) holds with equality.

**Proof of Theorem 5.7** We shall verify equality in (21) by induction over $s$. For $s = 0$, we have $S(K^{0}) = S(p_{s}) = H_{k}^{s}(G_{d})$. Now, fix $0 < s ≤ |\{\ell(\lambda), \ldots, d - \ell(\lambda)\}| - 1$, and assume that the equality holds for all $s^{′} ≤ s$. We consider an arbitrary positive definite zonal kernel $K : \mathbb{R}^{d \times d} \times \mathbb{R}^{d \times d} \rightarrow \mathbb{R}$ of degree at most $|\lambda| + s$ such that

$$
S(K|_{G_{d} \times G_{d}}) \supseteq H_{2k}^{d}, \quad S(K|_{G_{d} \times G_{d}}) \subset H_{k}^{s}(G_{d}),
$$

(37)

According to invariant theory, cf. [42, Theorem 7.1], the restriction $K|_{G_{d} \times G_{d}}$ is a linear combination of terms of the form

$$
\text{Tr}(X)^{k′} \text{Tr}(Y)^{l′} \prod_{i=1}^{\ell(\lambda′)} \text{Tr}((XY)^{\lambda′_{i}}), \quad k′ + |\lambda′|, l′ + |\lambda′| ≤ |\lambda| + s.
$$

Since any polynomial $\prod_{i=1}^{\ell(\lambda′)} \text{Tr}(X^{\lambda′_{i}})$ can be expanded into zonal polynomials $C_{\lambda′}(X)$ with $|\lambda′''| = |\lambda′|$, there are polynomials $r_{\lambda′} : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ of degree at most $|\lambda| + s - |\lambda′|$, such that

$$
K(P, Q) = \sum_{|\lambda′| \leq |\lambda| + s} r_{\lambda′}(\text{Tr}(P), \text{Tr}(Q)) C_{\lambda′}(P Q), \quad P, Q \in G_{d}.
$$

Moreover, due to (32) and the second and third property in (37), the kernel $K|_{G_{d} \times G_{d}}$ is also even or odd if $|\lambda| + s$ is even or odd, respectively, i.e.,

$$
K(P, Q) = (-1)^{|\lambda| + s} K(P, I - Q), \quad P, Q \in G_{d}.
$$

(38)

According to Corollary 5.6 and $S(K|_{G_{d} \times G_{d}}) \supseteq H_{2k}^{d}$, there is a function $q : \mathbb{R} \rightarrow \mathbb{R}$, such that

$$
K(P, Q) = q(\text{Tr}(P))q(\text{Tr}(Q)) p_{\lambda}(P, Q), \quad P, Q \in G_{d}.
$$

We now compare coefficients of $C_{\lambda}(P Q)$ on $G_{k} \times G_{l}, k, l \in \mathcal{I} := \{\ell(\lambda), \ldots, \lfloor \frac{d}{2} \rfloor\}$ in both expansions. We obtain $r_{\lambda}(k, l) = q(k)q(l)$, for $k, l \in \mathcal{I}$. Since $S(K|_{G_{d} \times G_{d}}) \supseteq H_{2k}^{d}$, the kernel $K|_{G_{d} \times G_{d}}$ does not completely vanish on $G_{d}$, so that there is $k′ \in \mathcal{I}$ such
that $q(k') \neq 0$ implying $q(l) = r_\lambda(k', l)/q(k')$, for $l \in I$. Furthermore, the symmetry (38) and (33) implies $q(d - l) = (-1)^s q(l)$ for $l \in I$, so that Lemma B.1 yields

$$q(d - l) = (-1)^s q(l) = (-1)^s r_\lambda(k', l)/q(k') = r_\lambda(k', d - l)/q(k'), \quad l \in I.$$ 

Hence, $q(l) = r_\lambda(k', l)/q(k')$, $l \in \{\ell(\lambda), \ldots, d - \ell(\lambda)\}$, and $q|_{\ell(\lambda),\ldots,d-\ell(\lambda)}$ is the restriction of a polynomial of degree at most $s$. The choice of $K$ and the induction hypothesis yield $K|_{G_d \times G_d} \ast K^*_\lambda \equiv 0$, for $i = 0, \ldots, s - 1$, which is equivalent to the orthogonality conditions

$$\sum_{m=\ell(\lambda)}^{d-\ell(\lambda)} q_\lambda^i(m)q(m)|v_\lambda^m|^2 = 0, \quad i = 0, \ldots, s - 1.$$ 

Thus, $q_\lambda^s|_{\ell(\lambda),\ldots,d-\ell(\lambda)}$ and $q|_{\ell(\lambda),\ldots,d-\ell(\lambda)}$ are linearly dependent, so that $K|_{G_d \times G_d} = cK^*_\lambda$, for some constant $c \neq 0$, implying $S(K|_{G_d \times G_d}) = S(K^*_\lambda)$. Since $K$ was an arbitrary kernel with the property (37), we derive $H^{|\lambda|+s}_{\lambda}(G_d)/H^{|\lambda|+s-1}_{\lambda}(G_d) \cong H^d_{2\lambda}$, so that (21) yields the assertion for $s$. 

\textbf{Appendix D. The Reproducing Kernels for $|\lambda| = 0, 1, 2$}

Let $K_{2\lambda} : \mathbb{R}^{d \times d}_{\text{sym}} \times \mathbb{R}^{d \times d}_{\text{sym}} \to \mathbb{R}$ denote the reproducing kernel (with respect to the differentiation inner product) of the irreducible representation $H^d_{2\lambda}$ in Hom$_{|\lambda|}(\mathbb{R}^{d \times d}_{\text{sym}})$. For $|\lambda| = 0, 1, 2$ and $X, Y \in \mathbb{R}^{d \times d}_{\text{sym}}$, we obtain

$$K_{(0)}(X, Y) = 1, \quad K_{(2)}(X, Y) = \text{Tr}(XY) - \frac{\text{Tr}(X)\text{Tr}(Y)}{d},$$

$$K_{(4)}(X, Y) = \frac{\text{Tr}(XY)^2 + 2\text{Tr}((XY)^2)}{6} + \frac{(\text{Tr}(X)^2 + 2\text{Tr}(X^2))(\text{Tr}(Y)^2 + 2\text{Tr}(Y^2))}{6(d+2)(d+4)},$$

$$K_{(2,2)}(X, Y) = \frac{\text{Tr}(XY)^2 - \text{Tr}((XY)^2)}{3} + \frac{(\text{Tr}(X)^2 - \text{Tr}(X^2))(\text{Tr}(Y)^2 - \text{Tr}(Y^2))}{3(d-1)(d-2)},$$

$$- \frac{\text{Tr}(XY)\text{Tr}(X)\text{Tr}(Y) - \text{Tr}(X^2)\text{Tr}(X) - \text{Tr}(X\text{Tr}(X)^2)\text{Tr}(Y) + \text{Tr}(X^2\text{Tr}(Y)^2)}{3(d-2)/2}. $$

The kernel $K_{(2,2)}$ is only defined for $d \geq 3$ and $K_{(2,2)} \equiv 0$ for $d = 3$. This is in accordance with the decomposition of Hom$_2(\mathbb{R}^{d \times d}_{\text{sym}})$, where the irreducible representation $H^d_{(2,2)}$ only occurs for $d \geq 4$, cf. (7). The restriction $K_{2\lambda}|_{G_d \times G_d}$ coincides with $p_\lambda$ up to a multiplicative constant. Indeed, we obtain

$$p_{(0)} = 1|_{G_d \times G_d}, \quad p_{(2)} = 2K_{(4)}|_{G_d \times G_d},$$

$$p_{(1)} = K_{(2)}|_{G_d \times G_d}, \quad p_{(1,1)} = 2K_{(2,2)}|_{G_d \times G_d}. $$

\textcopyright Springer
Further restricting $p_\lambda$ to $G_{I,d} \times G_{I,d}$ yields the reproducing kernel of $H^{[\lambda]}_\lambda(G_{I,d})$. The intertwining polynomials $p^{k,l}_\lambda = (v^k_\lambda v^l_\lambda)^{-1} p_\lambda|_{G_{k,d} \times G_{l,d}}$ are derived from

\[
\begin{align*}
  v^k_{(0)} &= 1, & v^k_{(2)} &= \sqrt{8k(k+2)(d-k)(d-k+2)} \\
  v^k_{(1)} &= \sqrt{\frac{2k(d-k)}{(d-1)d(d+2)}}, & v^k_{(1,1)} &= \sqrt{\frac{8(k-1)(k-d)(d-k)(d-1)(d+1)(d+2)}{(d-3)(d-2)(d-1)(d+1)(d+2)}}.
\end{align*}
\]

Reproducing kernels of the subspaces of $H^{[\lambda]+s}_{\lambda}(G_{I,d})$ equivalent to $H^d_{2\lambda}$ with increasing polynomial degree can be derived by restrictions of the kernels $K^l_\lambda$ in the proof of Theorem 5.7, cf. (20).
