Abstract

Background: There is a great variance between the extent of pneumatisation of the sphenoid sinuses that can reach beyond the body of the sphenoid bone. The purpose of this study was to find the frequency prevalence of the recesses of the sphenoid sinuses in Polish adult population.

Materials and methods: 296 computed tomography (CT) scans of patients who did not
present any pathology in the sphenoid sinuses were evaluated in this retrospective analysis. Spiral CT scanner — Siemens Somatom Sensation 16 — was used to glean the medical images. Standard procedure applied in the option Siemens CARE Dose 4D. No contrast medium was administered.

**Results:** In the majority of the patients — 93.92%, the pneumatisation of the sphenoid sinuses expanded beyond the body of the sphenoid bone, hence there were recesses of the sinuses present. The most common variant was the prevalence of two recesses — 12.84% of the cases. The frequency prevalence of all the 17 recesses was only 0.34%. Amongst the uneven recesses present, the sphenoidal rostrum’s recess (61.15% of the patients) and the inferior clinoid recess (56.42%) were the most common. Amongst the even recesses present, the lateral recess was prevalent in the majority (65.88%), whereas the posterior clinoid process’ recess was the least common (9.8%).

**Conclusions:** Presence of the recesses might facilitate access to the cranial fossae, hence comprehensive evaluation of the sphenoid sinuses is of immense importance in order to avoid unnecessary drills through the hard bone, that could potentially damage the nearby neurovascular structures.

**Key words:** sphenoid sinus, recess, anatomy, otorhinolaryngology, neurosurgery

**INTRODUCTION**

The body of the sphenoid bone contains pneumatic spaces filled with air, lined with mucous membrane, known as the sphenoid sinuses. Usually denoted as right and left, separated by the main septum, they are known to have a vastly varied morphology. Some of the most notable discrepancies between them include: their dimensions, relation to the surrounding neurovascular entities, the number of septa present, and the degree to which they are aerated (pneumatised) [20-23]. Henceforth, it is extremely difficult to assign one variation as a “normal anatomical variant” of the sphenoid sinuses due to the scarcity of unequivocal patterns found [21].

Previous studies reported that the sphenoid sinuses begin to develop approximately
around the 3rd-4th month of gestation, as a result of bilateral intussusception of the nasal mucosa in the direction of the sphenoid bone [13, 52]. It is possible to find the yet not pneumatised sinuses in the newborn which at that period of their development form small cavities within the sphenoid body [9]. This primary process of aeration is a form of continuation of the sphenethmoidal recess [30]. The proper pneumatisation of the sphenoid sinuses commences postnatally (around the age of 3-4), but the exact moment of termination of this process is not known (approximately 12-16 years of age), usually with completely aerated sinuses in the third decade of life [55]. This secondary process of aeration involves the growth of connective tissue into the viscerocranium [30].

Notwithstanding, quite often the pneumatisation of the sphenoid sinuses reaches beyond the body of the sphenoid bone, forming recesses. It might involve other parts of the sphenoid bone (e.g. lesser and greater wings, pterygoid process) and/or neighbouring bones (e.g. vomer, palatine bones) [21]. As such they become a matter of clinical importance during invasive procedures carried out within the lumen of the sinuses. For example, presence of the anterior clinoid process pneumatisation (the posterolateral recess) might lead to pneumocephalus or rhinorrhoea [51], but its presence is also useful while accessing aneurysms of the paraclinoid and supraclinoid parts of the internal carotid artery or central nervous system tumours in that region [2].

Preoperative comprehensive evaluation of the sphenoid sinus and its neighbouring neurovascular entities is of immense importance in order to perform a safe procedure and diminish the risk of iatrogenic complications [1, 14, 15, 25, 27, 28, 34, 35, 37, 40, 48]. Computed tomography (CT) scan is regarded as one of the most accurate methods of gleaning the medical images of the paranasal sinuses, as it allows to pinpoint a clear-cut representation of the osseous structures and identify anatomical variations. Most certainly it provides a more accurate information regarding the variant morphology of the sphenoid sinuses than the data provided from cadaveric dissections [6].

Endoscopic approaches are said to be the golden standard for the treatment of cerebrospinal fluid (CSF) leakage [3] and facilitate access to various pathologies found “between the frontal sinus and the upper border of lower 1/3 of the clivus (dens) in the sagittal plane or those between the 2 orbits superiorly and jugular foramens inferiorly in the paramedian plane” [50]. The minimally invasive endoscopic techniques allowed
medical professionals to decrease the number of classical extensive surgical interventions performed in this region.

The primary aim of this study was to present the up-to-date prevalence of the recesses of the sphenoid sinuses of Polish adult patients by the means of CT imaging in order to aid physicians in carrying out invasive endoscopic procedures in that region. The secondary outcome of the study was the subgroup analysis of females and males so as to evaluate whether there are any statistically significant differences between the presence of the particular recesses and gender. To the best knowledge of the authors this is the first study that has comprehensively taken into the account the possible impact of patients’ sex upon the prevalence of all the possible sphenoid sinus’ recesses.

MATERIALS AND METHODS

The researchers had access to a total of 359 medical images of patients referred to the Department of Medical Imaging of the University Hospital in Kraków to undergo a CT scan. In order to participate in this study, the patients had to be over eighteen years old and present no pathologies in the sphenoid sinuses. Patients who had suffered from a head trauma or had undergone nasal, orbital or cranial basis surgery prior to the research, were not included in the following analysis (63 patients). 296 patients (147 females, 149 males) fulfilled the inclusion criteria and were hence included in this retrospective analysis.

Standard procedure applied in the option Siemens CARE Dose 4D while obtaining the CT scans via spiral CT scanner Siemens Somatom Sensation 16. Contrast medium was not administered to any of the patients. Multiplans reconstruction tool was used in order to reconstruct the images in the coronal and sagittal planes, after the CT images in the axial planes were gleaned in the first instance. Diagnostic station Siemens Volume Wizard applied in order to evaluate the medical imaging data. Seven researchers evaluated the obtained data (JJT, JAW, ML, JZ, KB, JJZ, MPZ).

The analysis of the obtained images involved the presence of the sphenoid sinuses’ recesses (depending on the direction of the pneumatisation), as adapted from the classification of the previous authors [8, 10, 38]:
1. The median pneumatisation:
   • in the anterior direction:
     – the sphenoidal rostrum’s recess (in the direction of the sphenoidal rostrum);
     – the septal recess (in the direction of the main septum of the sphenoid sinuses);
     – the vomeral recess (in the direction of the vomer);
   • in the posterior direction:
     – the superior clinoid recess (in the dorsal direction of the sella turcica; in case of this recess, presence of the pneumatisation of the posterior clinoid process was also taken into the account);
     – the inferior clinoid recess (in the direction of Blumenbach’s clivus).

2. The lateral pneumatisation:
   • the anterolateral recess (in the direction of the lesser wing of the sphenoid bone, superior to the optic canal);
   • the posterolateral recess (in the direction of the lesser wing of the sphenoid bone, comprising the anterior clinoid processes);
   • the lateral recess (in the direction of the greater wing of the sphenoid bone if the pneumatisation crossed the conventional line between the foramen rotundum and the pterygoid / Vidian canal);
   • the pterygoid recess (in the direction of the pterygoid process of the sphenoid bone);
   • the palatine recess (in the direction of the palatine bone).

Statistical analysis in this study was conducted with the help of STATISTICA version 13.3 by TIBCO Software Inc®. Chi\(^2\) test, Mann-Whitney’s test and Fisher’s exact test were utilised whilst probing for differences between the presence of the particular recesses and gender. A statistically significant value of p < 0.05 was chosen for all the results.

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. For this type of study, formal consent is not required.
RESULTS

In the majority of the patients included in the study — 278 (136 females, 142 males), the pneumatisation of the sphenoid sinuses reached beyond the body of the sphenoid bone, hence there were recesses of the sinuses present. Only in 18 patients (11 females, 7 males) the recesses did not develop. Presence of two recesses was the most common variant — found in 38 patients (15 females, 23 males), sporadically there were more than ten recesses present, whereas presence of all the 17 recesses was noted only in one patient. The distribution of the frequency prevalence of the number of the recesses differed significantly between males and females (p=0.012, Mann-Whitney’s test). The total number of all of the recesses found is collected in Table I.

Amongst the uneven recesses, the sphenoidal rostrum’s recess was prevalent the most often (in 181 patients — 80 females, 101 males), but the inferior clinoid recess was also present in the majority of the patients (167 — 71 females, 96 males). The pneumatisation of the main septum was the least common (noted only in 26 patients — 8 females, 18 males). Amongst the even recesses, the lateral recess was prevalent the most often (in 195 patients — 97 females, 98 males), whereas the rarest variant was the presence of the posterior clinoid process’ recess (only in 29 patients — 4 females, 25 males).

There was a statistically significant difference between the proportion of females and males with the presence of the sphenoidal rostrum’s recess (p=0.018, Chi² test), the septal recess (p=0.045, Chi² test), the inferior clinoid recess (p=0.005, Chi² test), and the superior clinoid recess (p=0.045, Chi² test). No statistically significant difference was found between the proportion of females and males with the presence of the vomeral recess (p=0.639, Chi² test). (Table II)

There was a statistically significant difference between the proportion of females and males with the presence of the posterior clinoid process’ recess (p<0.001, Chi² test), and the anterolateral recess (p=0.003, Chi² test). Notwithstanding, no statistically significant difference was found between the proportion of females and males with the presence of the posterolateral recess (p=0.074, Chi² test), the lateral recess (p=0.969, Chi² test), the pterygoid recess (p=0.401, Chi² test), and the palatine recess (p=0.731, Chi² test). (Table III)
A statistically significant difference was found between the proportion of females and males with the presence of the posterior clinoid process’ recess (PCP) bilaterally (R+L) (p = 0.011, Chi^2 test), the PCP unilaterally (R/L) (p = 0.002, Chi^2 test), the anterolateral recess (A-L) R+L (p < 0.001, Chi^2 test), the posterolateral recess (P-L) R/L (p < 0.001, Chi^2 test), the P-L R/L (p = 0.034, Chi^2 test), and the lateral recess (La) R/L (p = 0.003, Chi^2 test). Nonetheless, no statistically significant differences were found between the proportion of females and males with the presence of the A-L R/L (p = 0.173, Fischer’s exact test), the P-L R+L (p = 0.910, Chi^2 test), the La R+L (p = 0.621, Chi^2 test), the pterygoid recess (P) R+L (p = 0.182, Chi^2 test), the P R/L (p = 0.728, Chi^2 test), the palatine recess (Pl) R+L (p = 0.938, Chi^2 test), and the Pl R/L (p = 0.719, Chi^2 test). (Table IV)

There was a statistically significant difference found between the proportion of males and females with PCP R+L present (p = 0.011, Chi^2 test), PCP R (p = 0.033, Chi^2 test), and A-L R+L (p<0.001, Chi^2 test). In the remaining variants, no statistically significant difference was noted between the proportion of genders with the respective recesses present: PCP (left unilateral location — L) (p = 0.067, Fischer’s exact test), A-L (right unilateral location — R) (p = 0.506, Chi^2 test), A-L L (p = 0.229, Chi^2 test), P-L R+L (p = 0.910, Chi^2 test), P-L R (p = 0.051, Chi^2 test), P-L L (p = 0.393, Chi^2 test), La R+L (p = 0.621, Chi^2 test), La R (p = 0.518, Chi^2 test), La L (p = 0.265, Chi^2 test), P R+L (p = 0.182, Chi^2 test), P R (p = 0.846, Chi^2 test), P L (p = 0.574, Chi^2 test), Pl R+L (p = 0.939, Chi^2 test), Pl R (p = 0.789, Chi^2 test), Pl L (p = 0.821, Chi^2 test). (Table V and VI, Figures 1-11)

**DISCUSSION**

In the majority of the patients — 93.92%, the pneumatisation of the sphenoid sinuses reached beyond the body of the sphenoid bone. The most common variant was the presence of two recesses — found in 12.84% of the case, sporadically there were more than ten recesses prevalent, whereas the presence of all the 17 recesses was noticed only in 0.34% of the patients (0.67% males).

Amongst the uneven recesses, the most common was the sphenoidal rostrum’s recess
Lower frequency prevalence of the superior clinoid recess was given by Hamid et al. [16] — 13.51%, but higher for the anterolateral recess (described as the pneumatisation of the sphenoidal plane) – 36.49%. It may be associated with the patient inclusion criteria (all the patients had a pituitary adenoma) and the ethnic group studied (the Egyptians).

Awadalla et al. [4] provided a different set of results. In the research group A (anatomical study of 25 skulls), they stated the following frequencies of the sinuses’ pneumatisation: the sphenoid body type (36%), the lateral type including the distinction between the greater wing type (12%), the pterygoid process type (16%), the clival recess (12%), the dorsal type (4%), the subdorsal type (4%) and the lesser wing type (12%). In the group B (radiological study: CT / MRI scans of 364 patients), Awadalla et al. [4] provided only the pneumatisation of the sphenoid body type (20%) and the lateral types: the greater wing type (5%) and the pterygoid process type (4%). Additionally, they stated the frequency prevalence for the full bilateral lateral pneumatisation (the bilateral pneumatisation of the greater wing and the pterygoid process) as 3.6% [4]. The dissimilar results may possibly be put down to the ethnicity of the patients (the Egyptians), the study method with which the sphenoid sinuses were researched (anatomical study of the skulls or MRI scans), the number of the skulls evaluated in the group A (25; from this group only skulls with the sellar type of pneumatisation were chosen and evaluated - 22 skulls) and the evaluation criteria of the types of pneumatisation (not stated in the work).

Definitely lower prevalence of the pneumatisation of the anterior clinoid process (the
The posterolateral recess was noted by Abuzayed et al. [2], who estimated it as 9.6% (2.1% on the right side, 1.7% on the left side, 5.7% bilateral). The aforementioned scientists divided the degree of pneumatisation into three types: the type I – less than 50% of the recesses was pneumatised (6.6%), the type II – more than 50% of the recesses was pneumatised, but they were not completely pneumatised (3.5%) and the type III – the completely pneumatised recesses (2.5%) [2].

Cope stated that the lumen of the sphenoid sinuses extends more often outside the body of the sphenoid bone anteriorly, posteriorly or laterally than it is confined to the body of the sphenoid [8]. He found the lateral recess (extending towards the greater wing of the sphenoid bone) in 24.66% (292 sinuses studied), but in a few instances (no specific number stated) the pneumatisation reached the pterygoid process of the sphenoid bone [8]. Furthermore, the author mentioned the presence of the very rare posterior recess (in the direction of the Blumenbach’s clivus) [8].

Idowu et al. noted a completely different set of results – they did not find any lateral recesses after studying 60 CT scans of their patients [19]. The dissimilarity between the data may be associated with the small research group and the Nigerian population studied. Yune et al. [56] noticed that the pneumatisation of the sphenoid sinuses varies from the minimal to relatively big (reaching the anterior or the posterior clinoid processes, the lesser or greater wings of the sphenoid bone or the pterygoid process), but they did not provide the frequency prevalence of the recesses.

Earwaker [10] in the researched material from 800 patients (CT scans of the paranasal sinuses) provided a similar frequency prevalence for the two and three recesses present in one patient (11.86% and 8.13% respectively). Notwithstanding, other results differ from the data found in the present study – the aforementioned researcher stated a higher presence of a single recess in one patient (17.13%), but lower frequency prevalence for multiple recesses in one patient. The author did not provide the number of the patients in whose sphenoid sinuses there were no recesses present nor there were more than thirteen recesses noted [10]. (Table VIII)

The vomeral recess, when present, poses a risk of a constricted access towards the sphenoidal sinus, as depending on its size it is possible that it would narrow the
sphenoethmoidal recess and hinder the way towards the ostium of the sphenoid sinus [5]. Similarly, the septal recess might impede the entrance to the sphenoid sinus via its ostium. In this study, the vomeral recess was present in 25.34%, whereas the septal recess in 8.78% of the patients.

The posterolateral recess (that comprises the anterior clinoid process) might be a useful variation aiding surgeons during the anterior clinoidectomy by pointing a safe limit during the drilling, if present [2]. As a medical professional reaches these air-filled cells, it warrants a more careful continuation of the surgery due to the closeness of nearby neurovascular structures with vigilance whilst removing the rest of this thin cortical bone [2]. In the proximity of the anterior clinoid process there can be found the following anatomical entities: the oculomotor nerve, the trochlear nerve, the ophthalmic nerve, and the clinoidal segment of the internal carotid artery. We would like to acknowledge Abuzayed et al. [2] in saying that the greater the aeration of the anterior clinoid process, the bigger the safe margin for controlled drilling, but the presence of the posterolateral recess necessitates its later closure after the procedure to diminish the risk of rhinorrhoea and CSF leakage from that region. Notwithstanding, it can also be an unusual site of development of mucocoele that might compress the nearby neurovascular structures, causing frontal or orbital headaches or signs and symptoms assigned to cranial nerves II to VI [47]. Henceforth it is crucial not to rupture the mucous membrane covering the lumen of the posterolateral recess, so as to diminish the risk of mucocoele [2]. In this study, the posterolateral recess was present in 32.09%, predominantly bilaterally (15.2% of the patients studied).

Presence of the lateral recess of the sphenoid sinuses noted preoperatively can be of immense importance, as it facilitates access to the lateral lesions of the cavernous sinus [29]. The size of the access point to the middle cranial fossa through the lateral recess has the following boundaries: inferiorly the Vidian nerve, superiorly the maxillary nerve, and posteriorly the terminal petrous and adjacent segments of the internal carotid artery [53]. Notwithstanding, a surgeon has to drill through the bone of the sphenoid in the proximity of the internal carotid artery when this recess is absent, a difficult task with the narrow endoscopic surgical field [29] that might result in iatrogenic injury to the artery. Moreover, it is probable that an infection of the sphenoid sinus might spread to the cavernous sinus
[26], especially when the bone separating them is thinned by the presence of the lateral recess. Furthermore, the lateral recess of the sphenoid sinus is a known point of origin of the CSF leakage, most often of spontaneous nature [54]. Shetty et al. [42] in their retrospective analysis of spontaneous sphenoid CSF leaks have found extensive lateral pneumatisation of the sphenoid sinus in 90% of their patients compared to 23% controls. Moreover there are reports noting temporal lobe meningoceles that herniated through the lateral recess into the sphenoid sinus [41]. Transsphenoidal approach towards the lateral recess might be attained with the help of angled endoscopes [50]. In this study, the lateral recess was present in 65.88% of the patients, predominantly bilaterally (40.88%).

The inferior clinoid recess might aid in approaching the posterior cranial fossa, especially since the extensive pneumatisation thins the clivus, making it easier to create the clival window [53]. As a result of the clival aeration, a surgeon can gain access to the space between the dorsum sellae and foramen magnum [53], possibly allowing for biopsy of brainstem lesions or approaching the surrounding CSF cisterns. The inferior clinoid recess was present in 56.42% of the patients studied.

In orthodontics, lateral cephalometric radiographic assessment is a crucial step whilst planning treatment. Sinha et al. [43] have suggested a possible correlation between the dimensions of the sella turcica and its skeletal pattern. Presence of the recesses of the sphenoid sinus might modify the shape and dimensions of the sella, hence their prevalence and impact could be the future direction of research in this area.

The extensive pneumatisation brings the lumen of the sphenoid sinus closer to crucial neurovascular structures, e.g. the maxillary nerve or the Vidian nerve, but fortunately intraoperative fluoroscopic imaging or navigational devices are utilised to curtail the risk of iatrogenic damage to these structures [6]. Some of the most modern techniques of analysing anatomical entities prior to a surgery is the use of the virtual dissection tables (VDT). Stecco et al. [44] reported that the VDTs helped with stating a more confident diagnosis of perplexing Le Fort fractures (the pterygoid process of the sphenoid bone is involved in all of the types of these fractures), compared to the single use of the standard Picture Archiving and Communication System (PACS). Preoperational planning of a transsphenoidal surgery with the help of VDT might possibly further assist surgeons in preparation for the procedure in the nearby future, thus enabling better
outcomes and quality of the surgery.

CONCLUSIONS

In the majority of the patients, the pneumatisation of the sphenoid sinuses reached beyond the body of the sphenoid bone, hence there were recesses of the sinuses present. The most common were two recesses of the sphenoid sinuses. The lateral, sphenoidal rostrum’s and inferior clinoid recesses where the most prevalent types (65.88%, 61.15% and 56.42% respectively). Comprehensive preoperational CT evaluation of the sphenoid sinuses should most certainly involve the analysis of presence of the recesses in every case, as they might facilitate access to the cranial fossae that could potentially be less traumatic than drilling through the hard cortical bone of the sphenoid.

Ethical approval

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. For this type of study formal consent is not required.

F – females, F% – the percentage of females, M – males, M% – the percentage of males

Table II. The frequency prevalence of the uneven recesses in the sphenoid sinuses – the types of the recesses.

| The recess            | F  | F%   | M  | M%   | F + M | F + M% |
|-----------------------|----|------|----|------|-------|--------|
| Sphenoidal rostrum’s  | 80 | 54.42%| 101| 67.79%| 181   | 61.15% |
| Septal                | 8  | 5.44% | 18 | 12.08%| 26    | 8.78%  |
| Vomeral               | 39 | 26.53%| 36 | 24.16%| 75    | 25.34% |
### Table III.
The frequency prevalence of the even sphenoid sinuses’ recesses – the types of the recesses.

| The recess       | F   | F%   | M   | M%  | F + M | F + M% |
|------------------|-----|------|-----|-----|-------|--------|
| Post. clin. proc. | 4   | 2.72%| 25  | 16.78% | 29    | 9.8%   |
| Anterolateral    | 29  | 19.73%| 52  | 34.9% | 81    | 27.36% |
| Posterolateral   | 40  | 27.21%| 55  | 36.91%| 95    | 32.09% |
| Lateral          | 97  | 65.99%| 98  | 65.77%| 195   | 65.88% |
| Pterygoid        | 59  | 40.14%| 67  | 44.97%| 126   | 42.57% |
| Palatine         | 72  | 48.98%| 70  | 46.98%| 142   | 47.97% |

### Table IV.
The frequency prevalence of the even sphenoid sinuses’ recesses, taking into the account the unilateral and bilateral location – the types and location of the recesses.

|     | F   | F%   | M   | M%  | F + M | F + M% |
|-----|-----|------|-----|-----|-------|--------|
| PCP R+L | 1   | 0.68%| 9   | 6.04%| 10    | 3.38%  |
| PCP R/L  | 3   | 2.04%| 16  | 10.74%| 19    | 6.42%  |
| A-L R+L | 15  | 10.2%| 44  | 29.53%| 59    | 19.93% |
| A-L R/L  | 14  | 9.52%| 8   | 5.37%| 22    | 7.43%  |
| P-L R+L | 22  | 14.97%| 23  | 15.44%| 45    | 15.2%  |
| P-L R/L  | 18  | 12.24%| 32  | 21.48%| 50    | 16.89% |
| La R+L  | 58  | 39.46%| 63  | 42.28%| 121   | 40.88% |
| La R/L  | 39  | 26.53%| 35  | 23.49%| 74    | 25%    |
| P R+L  | 28  | 19.05%| 38  | 25.5%| 66    | 22.3%  |
| P R/L  | 31  | 21.09%| 29  | 19.46%| 60    | 20.27% |
| Pi R+L | 45  | 30.61%| 45  | 30.2%| 90    | 30.41% |
| Pi R/L  | 27  | 18.37%| 25  | 16.78%| 52    | 17.57% |

R+L – bilateral location, R/L – unilateral location, PCP – posterior clinoid process’ recess, A-L – the anterolateral recess, P-L – the posterolateral recess, La – the lateral recess, P – the pterygoid
recess, Pl – the palatine recess, F – females, F% – the percentage of females, M – males, M% – the percentage of males

**Table V.** The frequency prevalence of the even sphenoid sinuses’ recesses, taking into the account the unilateral and bilateral location, as well as the right and left sides (in case of the unilateral location) – the types and the location of the recesses.

| The recess         | F  | F%  | M  | M%  | F + M | F + M% |
|--------------------|----|-----|----|-----|-------|--------|
| PCP R+L            | 1  | 0.68% | 9  | 6.04% | 10 | 3.38% |
| PCP R              | 2  | 1.36% | 9  | 6.04% | 11 | 3.72% |
| PCP L              | 1  | 0.68% | 7  | 4.7%  | 8  | 2.7%  |
