On the semiclassical limit of 4d spin foam models

Florian Conrady and Laurent Freidel

Perimeter Institute for Theoretical Physics, Waterloo, Ontario, Canada

We study the semiclassical properties of the Riemannian spin foam models with Immirzi parameter that are constructed via coherent states. We show that, in the semiclassical limit, the quantum spin foam amplitudes of an arbitrary triangulation are exponentially suppressed if the face spins do not correspond to a discrete geometry. When they do arise from a geometry, the amplitudes reduce to the exponential of $i$ times the Regge action. Remarkably, the dependence on the Immirzi parameter disappears in this limit.

I. INTRODUCTION

Loop quantum gravity (LQG) is an approach to canonical non–perturbative quantum gravity, where the first–order (or connection) formulation of gravity plays a central role. Spin foam models arise from the attempt to construct a corresponding covariant (or path–integral) formulation of quantum gravity. In both the canonical and covariant approach, one central open issue is the semiclassical limit—the question whether these theories reduce to general relativity in suitable semiclassical and low–energy regimes. This problem has been explored by many authors and from various angles: for example, by the use of semiclassical states, by the extraction of propagators from spin foam models, by numerical simulations and by symmetry reduction. At this stage, however, there is no conclusive evidence that LQG or spin foam models in 4 dimensions do have a satisfactory low–energy behaviour. More tangible results have been obtained in 3 dimensions, where the classical and quantum theory are far simpler. In this case, spin foams were coupled to point particles, and it was found that the semiclassical limit is related to a field theory on non–commutative spacetime.

Over the last years most investigations in 4 dimensions were focused on a model that was introduced by Barrett & Crane (BC) in 1997. It can be constructed by starting from a 4d BF theory and by imposing suitable constraints on the $B$–field. These constraints are called simplicity constraints and should restrict the $B$–field such that it becomes a wedge product of two tetrad one–forms. This procedure for imposing simplicity was subject to various criticisms: it was argued, in particular, that the BC model could not have a realistic semiclassical limit, since its degrees of freedom are constrained too strongly.

More recently, two new techniques for constructing spin foam models were introduced that open the way to a resolution of this difficulty: the coherent state method, based on integrals over coherent states on the group, and a new way of implementing the simplicity constraints. These techniques led to the definition of several new spin foam models: firstly, a model by Engle, Pereira & Rovelli (EPR), and later models by Freidel.
& Krasnov (FK\(\gamma\))\[26\] that incorporate any value of the Immirzi parameter \(\gamma \neq 1\) and reproduce the EPR model for \(\gamma = 0\)\[26, 27\]. Engle, Pereira, Livine & Rovelli\[28\] also studied the inclusion of the Immirzi parameter and proposed models (ELPR\(\gamma\)) which differ from FK\(\gamma\) for \(\gamma > 1\). A detailed comparison of the Riemannian models has been performed in \[30\]. Lorentzian versions of these models have been constructed as well \[26, 28, 29\].

In this paper, we focus our study on the set of Riemannian models FK\(\gamma\). The main reason for this is the result of \[30\], where we showed that each of these models can be written as a path integral with an explicit, discrete and local action. We will use this path integral representation to analyze the semiclassical properties of the spin foam models FK\(\gamma\).

As shown in \[30\], all known 4d spin foam models with gauge group SO(4) can be written in a unified manner. One first introduces a vertex amplitude \(A_v(j_f^+, l_e, k_{ef})\) which depends on a choice of SO(4) representations for each face \(f\) of the spin foam, a choice of SU(2) intertwiners \(l_e\) for each edge, and a choice of SU(2) representations \(k_{ef}\) for each “wedge” (i.e. each pair \((e,f)\)). This vertex amplitude is just the SO(4) 15j symbol with SO(4) representations expanded onto SU(2) ones (see \[30\] for more details). If one sums these vertex amplitudes without any constraint one simply obtains a spin foam representation of SO(4) BF theory.

The spin foam models for gravity arise from two restrictions: firstly, a restriction on the SO(4) spins in terms of the Immirzi parameter \(\gamma\), namely

\[
\frac{j^+}{j^-} = \frac{1 + \gamma}{|1 - \gamma|},
\]

which implements part of the simplicity constraints\[1\]. This implies that there is only one free SU(2) spin per face, denoted by \(j_f\). The second restriction pertains to the set of SU(2) “wedge” representations that one should sum over. It is expressed by the choice of a non–trivial measure \(D_{j,k}^\gamma\). The cross simplicity constraints require \[26, 28\] that this measure should be peaked around \(k = j^+ - j^-\) for \(\gamma > 1\). In the ELPR\(\gamma\) models, this constraint is imposed strongly, à la Barrett–Crane, while in the coherent state construction of FK\(\gamma\) it is implemented weakly.

The partition function of the spin foam models is given by a sum over spin foams that reside on the dual of a triangulation \(\Delta\) and satisfy the above constraints:

\[
Z_\Delta = \sum_{j_f} \prod_f d_{j_f^+} d_{j_f^-} W_\Delta^\gamma(j_f),
\]

where

\[
W_\Delta^\gamma(j_f) \equiv \sum_{l_e, k_{ef}} \prod_{e} d_{l_e} \prod_{ef} d_{k_{ef}} D_{j_f, k_{ef}}^\gamma \prod_{v} A_v^\gamma(j_f, l_e, k_{ef}).
\]

Here, the amplitude \(W_\Delta^\gamma(j_f)\) contains the sum over all intertwiner and wedge labels \(l_e\) and \(k_{ef}\), and can thus be regarded as an “effective” spin foam amplitude for given spins \(j_f\). \(d_j\) denotes the dimension of the spin \(j\) representation.

The main focus of our work is to find the semiclassical asymptotics of this effective spin foam amplitude. As we will see in the next section, this amounts to determine the behaviour of \(W_\Delta^\gamma(j_f)\) for large spins. We will find that, in this limit, the effective amplitude

\[1\] These models are only defined for \(\gamma \neq 1\). We also assume that \(\gamma \geq 0\), since a change of sign \(\gamma \to -\gamma\) is equivalent to swapping \(j^+\) and \(j^-\).
is exponentially suppressed if the spin labelling cannot be interpreted as areas of a discrete geometry. When the spins do arise from a discrete geometry, on the other hand, and when \( \gamma > 0 \), the effective amplitude \( W_{\Delta}(j_f) \) is given by the exponential of \( i \) times the Regge action. It is remarkable that the dependence on the Immirzi parameter drops out. The corresponding analysis for the EPR model yields that the exponent vanishes, i.e. the effective action is zero.

The paper is organized as follows: in section \( \text{II} \) we review the path integral representation that is used to derive the semiclassical approximation. In section \( \text{III} \) we define the notion of semiclassical limit that we apply in this paper, and present the main result derived in the following sections. Section \( \text{IV} \) states the equations which characterize the dominant contributions to the semiclassical limit. In sec. \( \text{V} \) we rewrite these equations and project them from \( \text{SU}(2) \times \text{SU}(2) \) to \( \text{SO}(4) \). In section \( \text{VI} \) we introduce definitions of co–tetrad, tetrad and spin connection on the discrete complex. These are needed in section \( \text{VII} \) where we show that the solutions to the equations are given by discrete geometries. Finally, in sec. \( \text{VIII} \) we put everything together and state the asymptotic approximation of the effective spin foam amplitude \( W_{\Delta}(j_f) \).

II. PATH INTEGRAL REPRESENTATION OF SPIN FOAM MODELS

In this section, we review the path integral representation for the EPR and FK(\( \gamma \)) models derived in ref. [30] and introduce some notations and definitions for simplicial complexes and their duals.

In the following, \( \Delta \) denotes a simplicial complex and \( \Delta^* \) stands for the associated dual cell complex. We assume that \( \Delta \) is orientable. We refer to cells of \( \Delta \) as vertices \( p \), edges \( \ell \), triangles \( t \), tetrahedra \( \tau \) and 4–simplices \( \sigma \). The 0–, 1– and 2–cells of the dual complex \( \Delta^* \) are called vertices \( v \), edges \( e \) and faces \( f \) respectively. We will also need a finer complex, called \( S_{\Delta} \), which results from the intersection of the original simplicial complex \( \Delta \) with the 2–skeleton of the dual complex \( \Delta^* \). This leads to a subdivision of faces \( f \subset \Delta^* \) into so-called wedges, and each edge \( e \subset \Delta^* \) is split into two half–edges (see Fig. 1b). We refer to oriented half–edges by giving the corresponding pair \((ve)\) or \((ev)\). When an edge in \( S_{\Delta} \) runs from the center of a face \( f \) to the edge \( e \subset \partial f \), it is denoted by the pair \((fe)\). A wedge is either labelled by a pair \( ev \) or by the pair \( ef \), where \( f \) is the face that contains the wedge and \( e \) is the edge adjacent to the wedge that comes first w.r.t. the direction of the face orientation.

Given \( S_{\Delta} \) and an orientation of its faces \( f \), we define a discretized path integral that is equivalent to the spin foam sum \( \tilde{S}_\mathcal{A} \). The variables are spins \( j_f \) on faces, \( \text{SU}(2) \) variables \( u_e \) and \( n_{ef} \) on edges and wedges respectively, and \( \text{SU}(2) \times \text{SU}(2) \) variables \( g_{ve} \) and \( h_{ef} \) on half–edges. The set of \( (g_{ve}, h_{ef}) \) represents a discrete connection on the complex \( S_{\Delta} \). We distinguish two types of connection variables, since there are two kinds of half–edges in \( S_{\Delta} \): half–edges \( (ev) \) along the boundary \( \partial f \) of a face \( f \), and half–edges \( (ef) \) that go from an edge \( e \) in the boundary \( \partial f \) to the center of the face \( f \) (see Fig. 2). Given such a connection, and for a wedge orientation \([eve'f]\), we can construct the wedge holonomy \( G_{ef} = (G^+_{ef}, G^-_{ef}) \), where

\[
G_{ef} = g_{ve} g_{ve}' h_{ef} h_{fe} .
\]  

The other set of variables \( (j_f, u_e, n_{ef}) \) represent (pre–)geometrical data\(^2\). As we will see in more detail later, one can think of \( u_e \) as a unit 4–vector normal to the tetrahedron dual

\(^2\) A truly geometrical interpretation is only valid on–shell, when the closure constraint is imposed.
to $e$. The spin $j_f$ determines the area of the triangle dual to $f$ and $n_{ef}$ represents a vector normal to this triangle in the subspace orthogonal to $u_e$. We use these variables to define Lie algebra elements $X_{ef}^\gamma = (X_{ef}^{\gamma+}, X_{ef}^{\gamma-}) \in \mathfrak{su}(2) \oplus \mathfrak{su}(2)$ associated with wedges of $\mathcal{S}_\Delta$. They depend on the value of the Immirzi parameter $\gamma$ and are given by

$$X_{ef}^{\gamma+} \equiv \gamma^+ j_f n_{ef} \sigma_3 n_{ef}^{-1}, \quad X_{ef}^{\gamma-} \equiv -\gamma^- j_f u_e n_{ef} \sigma_3 n_{ef}^{-1} u_e^{-1}. \quad (5)$$

Here, $\sigma_i$ denotes the Pauli matrices. The spins $j_f$ are arbitrary non-negative half-integers. $\gamma^+$ and $\gamma^-$ are the integers with smallest absolute value that satisfy $\gamma^+ > 0$ and

$$\frac{\gamma^+}{\gamma^-} = \frac{\gamma + 1}{\gamma - 1}. \quad (6)$$

That is, if $\gamma > 1$, both $\gamma^+$ and $\gamma^-$ are positive integers, while for $\gamma < 1$, $\gamma^-$ is negative\(^3\). In the following, we sometimes use the notation

$$j^\gamma \equiv |\gamma|^ j_f. \quad (7)$$

In the particular cases $\gamma = 0$ and $\gamma = \infty$ (corresponding to the EPR and FK model), one recovers the usual simplicity relations \([20, 31]\), i.e. $j^+ = j^- = j$.

The action of the path integral is given by

$$S^\gamma_\Delta(j_f, u_e, n_{ef}; g_{e\bar{e}}, h_{ef}) = \sum_{e, f \supset e} \left( S(X_{ef}^{\gamma+}, G_{ef}^{\gamma+}) + S(X_{ef}^{\gamma-}, G_{ef}^{\gamma-}) \right), \quad (8)$$

where

$$S(X; G) \equiv 2|X| \ln \text{tr} \left[ \frac{1}{2} \left( 1 + \frac{X}{|X|} \right) G \right]. \quad (9)$$

In the last equality, $X = X^i \sigma_i$ is a $\text{SU}(2)$ Lie algebra element, $G$ an $\text{SU}(2)$ group element, $|X|^2 \equiv X^i X_i$ and the trace is in the fundamental representation of $\text{SU}(2)$. Note that by

\(^3\) In previous papers \([26, 30]\), a different convention was used, where both $\gamma^+$ and $\gamma^-$ are positive. This entails minus signs in various formulas, depending on whether $\gamma > 1$ or $\gamma < 1$. With the present convention, we no longer need to make this distinction, since the minus signs are absorbed into $\gamma^-$.  

Figure 1: (a) Face $f$ of dual complex $\Delta^\ast$. (b) Subdivision of face $f$ into wedges. The arrows indicate starting point and orientation for wedge holonomies.
definition $|X^\pm_{ef}| = j^\pm_e$. This action is invariant under gauge transformation labelled by $\text{SU}(2) \times \text{SU}(2)$ group elements $\lambda_e, \lambda_f, \lambda_v$ living at vertices, faces and edges of $\mathcal{S}_\Delta$:

$$
\mathbf{g}_{ev} \to \lambda_e \mathbf{g}_{ev} \lambda_v^{-1}, \quad \mathbf{h}_{ef} \to \lambda_e \mathbf{h}_{ef} \lambda_f^{-1}, \quad n_{ef} \to \lambda^+_e n_{ef}, \quad u_e \to \lambda^-_e u_e (\lambda^+_e)^{-1}. \tag{10}
$$

In order to evaluate this action for a general group element $G = P_0 G + i P_G$, where $P_G = P_i G \sigma_i$ and $P_0^2 + |P_G|^2 = 1$, it is convenient to decompose $G$ into a part parallel to $\hat{X} \equiv X/|X|$ and a part orthogonal to it:

$$
G = \sqrt{1 - |P_G \times \hat{X}|^2} \left( \cos \Theta \mathbf{1} + i \sin \Theta \hat{X} \right) + i \left( P_G - (P_G \cdot \hat{X}) \hat{X} \right). \tag{11}
$$

where $(P_G \times \hat{X})^i \equiv \epsilon^{ijk} P_G^j \hat{X}^k$ and $\cos \Theta = P_0^G / \sqrt{1 - |P_G \times \hat{X}|^2}$. The action is in general complex, since $S(X; G) = |X| \ln \left( 1 - |P_G \times \hat{X}|^2 \right) + 2i |X| \Theta. \tag{12}$

It is important to note that the real part of this action is always negative; $\text{Re}(S(X, G)) \leq 0$. It is zero only if $\hat{X}$ is parallel to $P_G$ or equivalently if the Lie algebra element $X$ commutes with the group element $G$. In this case the action is purely imaginary and has the “Regge” form $S(X; G) = 2i |X| \Theta$.

As shown in [30], the spin foam models $\text{FK}_\gamma$ introduced in [26] and described in (3) can be written as

$$
Z^-_\gamma(j_f) = \sum_{j_f} \prod_{f} d_{j^+_f} d_{j^-_f} W^-_\gamma(j_f), \tag{13}
$$

where the effective amplitude $W^-_\gamma$ is obtained by integration over all the variables$^4$ except $j_f$:

$$
W^-_\gamma(j_f) = \int \prod_{e} du_e \prod_{e, f \subseteq e} d_{j^+_f} d_{j^-_f} n_{ef} \int \prod_{v, e \subseteq v} d\mathbf{g}_{ev} \prod_{e, f \subseteq e} d\mathbf{h}_{ef} \mathcal{S}_\gamma(j_f, u_e, n_{ef}; g_{ev}, h_{ef}). \tag{14}
$$

### III. SEMICLASSICAL LIMIT

In this section, we define the notion of semiclassical limit that we investigate in this paper, and state our main results. We focus our interest on the effective amplitude $W^-_\gamma(j_f)$, which depends only on the scalars $j_f$ associated to each face. In order to define a semiclassical limit we need to reinstate the $\hbar$–dependence and introduce dimensionful quantities. The spins $j_f$ are then proportional to the physical area.

The Immirzi parameter enters in the relationship between the discrete bivector field $X^\gamma_{ef}$ and the dimensionful simple area bivector field $A^I_{ef}$ associated with the triangle dual to $f$:

$^4$ Note that thanks to the gauge symmetry described in [10] there is no need to integrate over the variables $u_e$. The effective amplitude obtained after integration over all variables except $j_f$ and $u_e$ is independent of $u_e$. 
namely,\(^5\)
\[
(16\pi\hbar G)X_{ef}^\gamma = \ast A_{ef} + \frac{1}{\gamma} A_{ef},
\]
when \(\gamma > 0\).

The simplicity of the area bivector implies that \(|A_{+}| = |A_{-}| \equiv A_f\), where \(A_f\) denotes the physical area of the triangle dual to \(f\). The relationship (15) can be written \((16\pi\hbar G)\gamma X_{ef}^\gamma = (1 \pm \gamma)A_{ef}^\pm\), which leads to
\[
\frac{A_f}{8\pi\hbar G} = (\gamma^+ + \gamma^-) j_f.
\]

We implement the semiclassical limit by taking \(\hbar\) to zero, while keeping the physical dimensionful areas \(A_f\) fixed. The previous equation (16) tells us that in this limit the spins \(j_f\) are uniformly rescaled to infinity. Thus, the semiclassical regime is reached by taking the limit \(N \to \infty\) of the amplitude \(W^\gamma(\Delta j_f)\) in (14).

Since the action is linear in \(j_f\), this corresponds to a global rescaling of the action by \(N\). Hence the limit \(N \to \infty\) is controlled by the stationary phase points of the exponent: the integral localizes as a sum over contributions from stationary phase points. Moreover, as we have seen, the action is complex with a negative real part. As a result, stationary phase points which do not lie at the maximum \(\Re(S^\gamma_\Delta) = 0\) are exponentially suppressed. Altogether this means that the semiclassical limit is controlled by stationary points of \(S^\gamma_\Delta\) which are also \textit{maxima} of the real part \(\Re(S^\gamma_\Delta)\). A more detailed discussion of the asymptotic analysis is given in sec. VIII. Before stating our main result, we have to recall that in the continuum the equivalence between gravity and the constrained BF formulation is only established if one imposes a condition of non-degeneracy on the \(B\) field\(^6\). We therefore need to distinguish between non-degenerate and degenerate configurations in our analysis. This is achieved by splitting the amplitude (14) into two parts\(^7\),
\[
W^\gamma(\Delta j_f) = W^{ND\gamma}(\Delta j_f) + W^{D\gamma}(\Delta j_f),
\]
where \(W^{ND\gamma}(\Delta j_f)\) is defined by the integral (14) subject to the constraint that
\[
|\epsilon_{ijklm} X_{ef}^{ij} (g_{ee'} \triangleright X_{ef'})^{klm}| > 0
\]
for all pairs of wedges \((ef)\) and \((e'f')\) that share a vertex, but do not share an edge. Here, \(g_{ee'} \triangleright X_{ef'} \equiv g_{ee'} \triangleright X_{ef'} g_{ee}^{-1}\) and \(g_{ee'} \equiv g_{ee} g_{ee'}\). The term \(W^{D\gamma}(\Delta j_f)\) denotes the complementary integral consisting of degenerate configurations.

One of the characteristics of 4d spin foam models is the assignment of spins \(j_f\) to each face \(f\) of the dual complex \(\Delta^*\) and of corresponding areas \(A_t(j_f)\) to each triangle \(t\) of \(\Delta\). In contrast, Regge calculus is based on an assignment of a discrete metric to the complex, defined by lengths \(l_\ell\) associated with each edge \(\ell \subset \Delta\) and subject to triangle inequalities. The areas \(A_t\) of triangles \(t\) dual to faces \(f\) are then determined as a function \(A_t(l_\ell)\) of the

\(^5\) The map between bivectors \(X_{ef}^{ij}\) and Lie algebra elements \(X_{ij} = (X^{+\dagger} \sigma_i, X^{-\dagger} \sigma_i)\) of \(\text{su}(2) \oplus \text{su}(2)\) is given by \(X_{ef}^{ij} = \frac{1}{2} \epsilon_{ijk} X_{ef}^{jk} \pm X_{ef}^{ij}\).

\(^6\) see \([21, 22]\) for a more detailed discussion of this point and the potential problems due to degenerate configurations in the path integral.

\(^7\) see \([32]\) for an analysis of stationary points of group integrals representing the \(6j\)- and \(10j\)-symbol using a similar splitting.
edge lengths \( l_\ell \). It is well-known \cite{33, 34, 35} that for an arbitrary assignment of spins \( j_f \), there is, in general, no set of \( l_\ell \)'s such that \( \kappa j_f = A_\ell (l_\ell) \). The set of areas \( A_\ell \) determines at least one flat geometry inside each 4-simplex, but the geometries of tetrahedra generally differ, when viewed from different 4-simplices. In the following, we will call an assignment of spins \( j_f \) Regge-like if there is a discrete metric \( l_\ell, \ell \subset \Delta \), such that \( A_\ell (j_f) = A_\ell (l_\ell) \).

Our principal result is that the set of stationary points of the integral (\ref{eq:start}) which are non-degenerate and have a maximal real part, are Regge-like. Moreover, the on-shell action is exactly the Regge action! This result relies on the specific realization of the spin foam model in terms of the local action (\ref{eq:local_action}) which is valid for the FK\( \gamma \) version \cite{26} of the model. It does not apply to the ELPR\( \gamma \) construction \cite{28}, which is different from FK\( \gamma \) for \( \gamma > 1 \) (see \cite{30} for a comparison).

More precisely, a configuration \((j_f, u_e, n_{ef}, g_{ev}, h_{fe})\) is a solution of the conditions

\[
\frac{\partial S}{\partial n_{ef}} = \frac{\partial S}{\partial u_e} = \frac{\partial S}{\partial g_{ev}} = \frac{\partial S}{\partial h_{ef}} = 0, \quad \text{Re} S = 0, \tag{19}
\]

and eq. (\ref{eq:elt}), if and only if the spins \( j_f, f \subset \Delta^* \), are Regge-like. In this case, there exist edge lengths \( l_\ell, \ell \subset \Delta \), such that \( j_f = (\gamma^+ + \gamma^-)^{-1} A_f (l_\ell) \) for \( f = t^* \). Moreover, for such a solution we have, as long as \( \gamma \neq 0 \), that

\[
S_\Delta^r = \sum_f A_f (l_\ell) \Theta_f (l_\ell) \equiv S_R (l_\ell), \tag{20}
\]

where \( \Theta_f (l_\ell) \) is the deficit angle associated with the face \( f \) and \( A_f (l_\ell) \) is the area in Planck units. If \( \gamma = 0 \), the on-shell action vanishes, i.e. \( S_\Delta^0 = 0 \), in agreement with the fact that \( \gamma = 0 \) corresponds to a topological theory classically (see \cite{26}).

It is important to note that the dependance on \( \gamma \) has disappeared from the functional form of the action. This parallels the behaviour of the continuum theory, where the \( \gamma \) dependence drops out classically, once we solve the torsion equation. It also provides a non-trivial check on whether the chosen spin foam model captures the right semiclassical dynamics. The dependence on the \( \text{Im} \)mirzi parameter arises only at the quantum level as a quantization condition on the area\(^8\), similar as in canonical loop quantum gravity.

These results are derived in section VII and VIII and imply the following statements on the effective amplitude \( W^{N^{D}\gamma} (j_f) \): as \( N \to \infty \), the amplitude \( W^{N^{D}\gamma} (N j_f) \) is exponentially suppressed\(^9\), if the spins \( j_f, f \subset \Delta^* \), do not arise from a Regge\( \gamma \) geometry. On the other hand, if the \( j_f \)'s are Regge-like, there is a non-zero function \( c_\Delta (j_f) \), independent of \( N \), such that

\[
W^{N^{D}\gamma} (N j_f) \sim \frac{c_\Delta (j_f)}{N^r_\Delta} (\exp (iN S_R) + c.c) \tag{21}
\]

as \( N \to \infty \). Here, \( c.c \) stands for the complex conjugate. The number \( r_\Delta \) is the rank of the Hessian and given by

\[
r_\Delta = 33E - 6V - 4F, \tag{22}
\]

with \( V, E \) and \( F \) denoting the number of vertices, edges and faces of \( \Delta^* \).

\(^8\) The dimensionful area has to satisfy the condition that \( A_\ell (8\pi \hbar G)^{-1} (\gamma^+ + \gamma^-)^{-1} \) is a half-integer. This quantization condition becomes invisible in the semiclassical limit \( \hbar \to \infty \).

\(^9\) That is, the limit \( N \to \infty \) of \( N^n W^{N^{D}\gamma} (N j_f) \) is equal to zero for all \( n \in \mathbb{N} \).
This shows that, in the semiclassical limit, the effective amplitude $W_{\Delta}^{ND\gamma}(j_f)$ is described by an effective action, which is the Regge action. If there are several discrete geometries $\ell, \ell \subset \Delta$, for a given set $j_f, f \subset \Delta^*$, one should sum over them in the asymptotic evaluation (21). In the following sections, we prove the above statements and study in detail the non-degenerate solutions to eqns. (19).

IV. CLASSICAL EQUATIONS

We will now derive the explicit form of the equations that follow from the conditions $\delta S = 0$ and $\text{Re} S = 0$.

A. Variation on interior and exterior edges

We first consider the variation of the variable $h^\pm_{e'f}$. Since the edge $e'f$ belongs to two wedges, denoted $ef$ and $e'f$, the variation of the action involves only two terms. If $e$ is the edge preceding $e'$ along the orientation of the face $f$, one has $G_{ef} = g_{ee'}g_{ee''}h_{e'f}h_{ef}$ and $G_{e'f} = g_{e'v'}g_{e'v''}h_{e'f}h_{f'v}$. We can write the variation of the action as (see Fig. 2)

$$\delta S = 2j_f^\pm \text{tr} \left[ \left( \frac{h_{e'e} \left( 1 + \hat{X}_{ef} \right) G_{ef} (h_{e'e})^{-1}}{\text{tr} \left( (1 + \hat{X}_{ef}) G_{ef} \right)} - \frac{(1 + \hat{X}_{e'f}) G_{e'f}^\pm}{\text{tr} \left( (1 + \hat{X}_{e'f}) G_{e'f}^\pm \right)} \right) \delta h_{e'f}^\pm h_{ef}' \right] = 0 \quad (23)$$

where we use the abbreviations

$$g_{ee'}^\pm \equiv g_{ee'}g_{ee''}, \quad h_{e'e}^\pm \equiv h_{e'e}h_{e'f}, \quad (h_{e'e})^{-1} = h_{f'e}, \quad (g_{ee'})^{-1} = g_{ee'}, \quad (24)$$

and $\hat{X}_{ef}^\pm \equiv X_{ef}^\gamma / j^\gamma$, which is independent of $\gamma$.

To write these equations in a more compact manner, let us define the matrix element

$$\hat{Y}_{ef}^\pm \equiv \frac{2(1 + \hat{X}_{ef}^\pm)}{\text{tr} \left( (1 + \hat{X}_{ef}^\pm) G_{ef}^\pm \right)} \quad (25)$$

Since $\delta hh^{-1}$ is in the Lie algebra, we conclude from (23) that the traceless part of the expression in round brackets has to be zero. Moreover, since $\text{tr} \left( Y_{ef}^\pm G_{ef}^\pm \right) = 2$, one simply
We refer to this equation as the \textit{interior closure constraint}, since it encodes a relation between wedges in the interior of the face \( f \).

Next, we vary a group variable \( g_{ev} \) on a half–edge \( ev \). This calculation is slightly more involved, since the orientation of different faces has to be taken into account. At the edge \( e \), four faces \( f_i, i = 1, \ldots, 4 \), intersect. Let \( I^+_e \) be the set of indices \( i \) for which the orientation of \( f_i \) is “ingoing” at the vertex \( v \), i.e. parallel to the orientation of the half–edge \( (ev) \). In these cases, the wedge holonomy has the form \( G_{ef_i} = g_{ev} g_{ve} h_{ef_i} h_{fe} \). Denote by \( I^-_e \) the complementary set for which the holonomy is \( G_{ef_j} = g_{ev} g_{ve} h_{ef_j} h_{fe} \). Then, variation of \( g_{ev} \) gives

\[
\delta S = \text{tr} \left[ \left( \sum_{i \in I^+_e} j^+_i (G_{ef_i} \hat{Y}_{ef_i} - \mathbb{1}) - \sum_{j \in I^-_e} j^-_j g_{ee_j} (G_{ef_j} \hat{Y}_{ef_j} - \mathbb{1}) (g_{ee_j})^{-1} \right) \delta g_{ev} g_{ve} \right] = 0 \tag{27}
\]

Again, the traceless part of the quantity in round brackets has to be zero. Therefore,

\[
\sum_{i \in I^+_e} j^+_i (G_{ef_i} \hat{Y}_{ef_i} - \mathbb{1}) - \sum_{j \in I^-_e} j^-_j g_{ee_j} (G_{ef_j} \hat{Y}_{ef_j} - \mathbb{1}) (g_{ee_j})^{-1} = 0 \tag{28}
\]

This equation relates wedges from different faces, so we call it the \textit{exterior closure constraint}.

\section*{B. Variation of \( u_e \) and \( n_{ef} \) and maximality}

For the variation w.r.t. \( n_{ef} \), we use the definition (5) of \( X_{ef}^\pm \) and get

\[
\delta X_{ef}^+ = \left[ \delta n_{ef} n_{ef}^{-1}, X_{ef}^+ \right], \quad \delta X_{ef}^- = \left[ u_e \delta n_{ef} n_{ef}^{-1} u_e^{-1}, X_{ef}^- \right]. \tag{29}
\]
The variational equation for $n_{ef}$ is therefore given by
\[
\left[ \dot{Y}^+_\text{ef}, G^+_\text{ef} \right] + u^{-1}_e \left[ \dot{Y}^-_{\text{ef}}, G^-_{\text{ef}} \right] u_e = 0. \tag{30}
\]
Similarly, by varying $u_e$ one obtains
\[
\sum_{f \not= e} \left[ \dot{Y}^-_{\text{ef}}, G^-_{\text{ef}} \right] = 0. \tag{31}
\]

The action being complex, its stationarity is not enough to determine the dominant contribution to the semiclassical limit. One also has to demand that the stationary points are a maximum of the real part of the action. Since
\[
\text{Re}(S^\gamma_{\text{ef}}) = \sum_{(ef)} \left[ j^+_f \ln \left( 1 - \frac{1}{4} \left[ \dot{X}^+_\text{ef}, G^+_\text{ef} \right]^2 \right) + j^-_f \ln \left( 1 - \frac{1}{4} \left[ \dot{X}^-_{\text{ef}}, G^-_{\text{ef}} \right]^2 \right) \right], \tag{32}
\]
and $|[X,G]|^2 \geq 0$, this is maximal when
\[
\left[ G^+_\text{ef}, \dot{X}^+_\text{ef} \right] = 0 = \left[ G^-_{\text{ef}}, \dot{X}^-_{\text{ef}} \right]. \tag{33}
\]
Note that the maximum condition implies that the stationarity equations (30,31) for $n_{ef}$ and $u_e$ are automatically fulfilled. Moreover it is important to notice that this relation leads to a drastic simplification of the closure constraints, since it leads to the identity:
\[
\dot{Y}^\pm_{\text{ef}} G^\pm_{\text{ef}} = G^\pm_{\text{ef}} \dot{Y}^\pm_{\text{ef}} = 1 + \dot{X}^\pm_{\text{ef}}. \tag{34}
\]

V. REWRITING THE EQUATIONS

A. Parallel transport to vertices

To analyze the variational equations, it is convenient to make a change of variables. The original variables $X^\gamma_{\text{ef}}, G_{\text{ef}}$ are based at the edge $e$, which means that under gauge transformation they transform as $(X^\gamma_{\text{ef}}, G_{\text{ef}}) \rightarrow (\lambda_e X^\gamma_{\text{ef}} \lambda_e^{-1}, \lambda_e G_{\text{ef}} \lambda_e^{-1})$. The new variables are based at $v$ and defined by parallel transporting the original variables to the nearest vertices of the dual complex $\Delta^*$:
\[
X^\gamma_{\text{ef}}(v) \equiv g_{ve} X^\gamma_{\text{ef}} g_{ve}^{-1}, \quad G_{\text{ef}}(v) \equiv g_{ve} G_{\text{ef}} g_{ve}^{-1}, \quad u_e(v) \equiv g^{-1}_{ve} u_e(g^+_e)^{-1}. \tag{35}
\]
Since every edge $e$ intersects with two vertices $v$ and $v'$, this leads to a doubling of the number of variables. This is compensated by equations that relate variables at neighbouring vertices $v$ and $v'$: i.e.
\[
X^\gamma_{\text{ef}}(v) = g_{ve} X^\gamma_{\text{ef}}(v')(g_{ve})^{-1}, \quad u_e(v') = g^{-1}_{ve} u_e(v)(g^+_e)^{-1}. \tag{36}
\]
In terms of the new variables, the interior closure constraint (26) becomes
\[
h^\pm_{fe} g_{ev} \left( \dot{Y}^\pm_{\text{ef}}(v) G^\pm_{\text{ef}}(v) \right) (h^\pm_{fe} g_{ev})^{-1} = h^\pm_{fe} g_{ev} \left( \dot{Y}^\pm_{\text{ef}}(v') G^\pm_{\text{ef}}(v') \right) (h^\pm_{fe} g_{ev})^{-1}. \tag{37}
\]
Thus,
\[ G_{ef}^\pm (v) \hat{Y}_{ef}^\pm (v) = \hat{Y}_{ef}^\pm (v) G_{ef}^\pm (v), \]
where the edge \( e' \) follows the edge \( e \) in the orientation of \( f \). Likewise, after conjugation by \( g_{ve}^\pm \), the exterior closure constraint takes the form
\[ \sum_{i \in I^+} j_{fi}^+ \left( G_{efi}^\pm (v) \hat{Y}_{efi}^\pm (v) - 1 \right) - \sum_{j \in I^-} j_{fj}^- \left( G_{efj}^\pm (v) \hat{Y}_{efj}^\pm (v) - 1 \right) = 0. \]
(39)

If we impose, in addition, the maximality constraint (34), the closure constraints simplify and we remain with the following set of equations:

\[
\begin{align*}
[ G_{ef}(v), X^\gamma_{ef}(v) ] &= 0, \quad X^\gamma_{ef}(v') = g_{v'e'} X^\gamma_{ef}(v) (g_{v'e'})^{-1}, \quad u_e(v') = g_{v'e'} u_e(v) (g_{v'e'})^{-1}, \\
X^\gamma_{ef}(v) &= X^\gamma_{e'f}(v), \quad \sum_{f \supset e} \epsilon_{ef}(v) X^\gamma_{ef}(v) = 0.
\end{align*}
\]
(40)

\( \epsilon_{ef}(v) \) is a sign factor which is 1 when \( f \) is ingoing at \( v \), i.e. oriented consistently with the half edge \( (ev) \), and \(-1\) otherwise. These equations are supplemented by the simplicity constraints
\[
X^\gamma_{ef}(v) = \left( \gamma^+ j_f \text{Ad}(n_{ef}(v)) \sigma_3, -\gamma^- j_f \text{Ad}(u_e(v)n_{ef}(v)) \sigma_3 \right),
\]
where
\[
n_{ef}(v) \equiv g_{ve}^+ n_{ef}(g_{ve}^+)^{-1}.
\]
(42)

**B. Projection to SO(4)**

In order to solve these equations explicitly it is convenient to project them from \( \text{SU}(2) \times \text{SU}(2) \) to \( \text{SO}(4) \) and work purely in terms of vectorial and \( \text{SO}(4) \) variables.

The action has the property that
\[
S^\gamma_\Delta(j_f, u_e, n_{ef}; -G_{ef}) = S^\gamma_\Delta(j_f, u_e, n_{ef}; G_{ef}) + 2i\pi(\gamma^+ + \gamma^-)j_f,
\]
so the weight \( \exp(S^\gamma_\Delta) \) projects down to a function of \( \text{SO}(4) \) if one restricts to configurations for which \( (\gamma^+ + \gamma^-)j_f \) is an integer. We assume from now on that this is the case.

The projection to \( \text{SO}(4) \) means that we work with bivectors \( X^{IJ} \) instead of pairs \( (X^+, X^-) \), the relation between the two being
\[
X^\pm_i = \frac{1}{2} \epsilon^j_3 X^{jk} \pm X_0i.
\]
(44)

We also associate a unit vector \( \hat{U}_e \) in \( \mathbb{R}^4 \) to each \( \text{SU}(2) \) element \( u_e \), defined by the relation
\[
u_e = \hat{U}_e^0 1 + i\hat{U}_e^i \sigma_i, \quad \hat{U}_e^2 = 1,
\]
(45)
where $\sigma_i$ are the Pauli matrices. To translate the simplicity constraints (41) to so(4), it is convenient to introduce a fiducial bivector field which is independent of $\gamma$ and which is simple unlike $X^\gamma$. We denote this bivector field by $X_{ef}$ without any subscript $\gamma$ and it is defined by

$$X_{ef}^\gamma = \gamma^+ X_{ef}^+ - \gamma^- X_{ef}^-.$$  

(46)

Due to the simplicity constraint (41), $u_e X_{ef}^+ + X_{ef}^- u_e = 0$ and $|X_{ef}^\pm| = j_f$. By using the identity

$$\frac{1}{2i} (u X^+ + X^- u) = (\ast X \cdot U)_{\gamma} + i(\ast X \cdot U)_\sigma \gamma^i, \quad (X \cdot U)_I \equiv X_{IJ} U^J, \quad (\ast X)_{IJ} \equiv \frac{1}{2} \epsilon_{IJKL} X^{KL}. \quad \text{(47)}$$

we then find that

$$X_{ef}^\gamma = \frac{1}{2} (\gamma^+ + \gamma^-) X_{ef} + \frac{1}{2} (\gamma^+ - \gamma^-) (\ast X_{ef}), \quad (\ast X_{ef}(v) \cdot \tilde{U}_e(v))^I = 0 \quad \text{(48)}$$

with $X_{ef}(v) \cdot X_{ef}(v) = 2j_f^2$. This equation is the discrete version of the simplicity constraints in the continuum. Recalling the definition of $\gamma$ in terms of $\gamma^\pm$, we can write the relation between $X^\gamma$ and $X$ also as

$$X_{ef}^\gamma = \frac{1}{2} (\gamma^+ + \gamma^-) \left( \ast X_{ef} + \frac{1}{\gamma} X_{ef} \right), \quad \text{(49)}$$

which shows that for $\gamma > 0$ $X$ plays the role of the dual of the area bivector:

$$X_{ef} = \frac{1}{\gamma^+ + \gamma^-} \ast A_{ef} \quad \text{8πℏG}. \quad \text{(50)}$$

Together with these simplicity conditions, we want to solve the equations (40). When written in terms of the $\gamma$–independent, simple bivector $X_{ef}$, they take the form

$$G_{ef}(v) \triangleright X_{ef}(v) = X_{ef}(v), \quad X_{ef}(v') = g_{v'v} \triangleright X_{ef}(v), \quad \tilde{U}_e(v') = g_{v'v} \tilde{U}_e(v), \quad \text{(51)}$$

where $\triangleright$ denotes the action of SO(4) generators on bivectors. This and eq. (48) are the final form of the equations that we will study now.

VI. DISCRETE GEOMETRY

In order to find the general solution, we will assume that the bivectors $X_f(v)$ are non–degenerate: that is,

$$X_{ef}(v) \wedge X_{e'f'}(v) \neq 0 \quad \text{(52)}$$
for any pair of faces \( f, f' \) which do not share an edge. It turns out that the solutions exist only if the set \((j_f)_f\) is Regge-like. That is, only if there is a discrete metric on the triangulation \( \Delta \) for which \( j_f \) is the area of triangles dual to \( f \). As we will see, the unit vectors \( \hat{U}^I \) are, on-shell, the normalized tetrad vectors associated with this metric and the connection \( g_{\nu\nu} \) is the discrete spin connection for this tetrad. In order to demonstrate these statements, we first need to define all these notions on the discrete complex\(^\text{10}\).

### A. Co–tetrads and tetrads on a simplicial complex

**Definition VI.1** A co–tetrad \( E \) on the simplicial complex \( \Delta \) is an assignment of vectors \( E_\ell(v) \in \mathbb{R}^4 \) to each vertex \( v \subset \Delta^* \) and oriented edge \( \ell \subset \Delta, \ell \subset \sigma = v^* \), where the following properties hold:

(i) \( E_{-\ell} = -E_\ell \).

(ii) For any triangle \( t \subset \sigma = v^* \), and edges \( \ell_1, \ell_2, \ell_3 \subset t \) s.t. \( \partial t = \ell_1 + \ell_2 + \ell_3 \), the vectors \( E_\ell(v) \) close, i.e.

\[
E_{\ell_1}(v) + E_{\ell_2}(v) + E_{\ell_3}(v) = 0 . \tag{53}
\]

(iii) For every edge \( e = v'v \subset \Delta^* \) and for any pair of edges \( \ell_1 \) and \( \ell_2 \) in the tetrahedron \( \tau \) dual to \( e \), we have

\[
E_{\ell_1}(v') \cdot E_{\ell_2}(v') = E_{\ell_1}(v) \cdot E_{\ell_2}(v) . \tag{54}
\]

In other words, a co–tetrad \( E \) is an assignment of a closed \( \mathbb{R}^4 \)–valued 1–chain \( E(v) \) to each 4–simplex \( \sigma = v^* \) that fulfills a compatibility criterion. In each 4–simplex \( \sigma^* = v \), the co–tetrad vectors \( E_\ell(v) \) define a flat Riemannian metric \( g_v \) by

\[
g_{\ell_1\ell_2}(v) = E_{\ell_1}(v) \cdot E_{\ell_2}(v), \quad \ell_1, \ell_2 \subset \sigma . \tag{55}
\]

Condition (iii) requires that, for any pair of 4–simplices \( \sigma = v^* \) and \( \sigma' = v'^* \) which share a tetrahedron \( \tau \), the metric induced on \( \tau \) by \( E(v) \) and \( E(v') \) are the same. Thus, the co–tetrad \( E \) equips \( \Delta \) with the structure of a piecewise flat Riemannian simplicial complex.

We call a co–tetrad \( E \) non–degenerate if at every vertex \( v = \sigma^* \subset \Delta^* \) and for every tetrahedron \( \tau \subset \sigma \), the span of the vectors \( E_\ell(v), \ell \subset \tau \), is 4–dimensional.

**Proposition VI.2** Given any non–degenerate co–tetrad \( E \), there is a unique \( SO(4) \) connection \( \Omega \) on \( \Delta^* \) that satisfies the condition

\[
E_{\ell}(v') = \Omega_{\nu\nu} E_\ell(v) \quad \forall v'v = e \subset \Delta^*, \ell \subset e^* . \tag{56}
\]

We call this connection \( \Omega \) the spin connection associated to \( E \).

**Proof** Let \( \hat{U}(v) \) and \( \hat{U}(v') \) denote unit normal vectors to \( E_{\ell_i}(v), i = 1, 2, 3 \), and \( E_{\ell_i}(v') \), \( i = 1, 2, 3 \), respectively. Choose these unit normal vectors such that

\[
\text{sgn det} \left( E_{\ell_1}(v'), E_{\ell_2}(v'), E_{\ell_3}(v'), \hat{U}(v') \right) = \text{sgn det} \left( E_{\ell_1}(v), E_{\ell_2}(v), E_{\ell_3}(v), \hat{U}(v) \right) . \tag{57}
\]

\(^{10}\) For previous definitions in the literature, see e.g. \[36, 37, 38\].
Since the tetrad is non–degenerate, we can find a matrix $\Omega_{\nu'\nu} \in \text{GL}(4)$ for which

$$\Omega_{\nu'\nu} E_{\ell_i}(v) = E_{\ell_i}(v'), \quad i = 1, 2, 3,$$

By condition (54), this matrix must be orthogonal, i.e. $\Omega_{\nu'\nu} \in \text{O}(4)$. From eq. (57), we also know that $\det \Omega = 1$, so $\Omega \in \text{SO}(4)$. Suppose now there were two matrices $\Omega_1, \Omega_2 \in \text{SO}(4)$ for which

$$\Omega_1 E_{\ell_i}(v) = E_{\ell_i}(v'), \quad \Omega_2 E_{\ell_i}(v) = E_{\ell_i}(v'), \quad i = 1, 2, 3.$$

This would imply that

$$\Omega_2^{-1}\Omega_1 E_{\ell_i}(v) = E_{\ell_i}(v'), \quad i = 1, 2, 3,$$

and hence $\Omega_2 = \Omega_1$. Therefore, the group element $\Omega_{\nu'\nu}$ is unique. \hfill \blacksquare

Together, the closure condition (53) and equation (56) can be regarded as a discrete analogue of the torsion equation $DE = 0$.

In analogy to the continuum, we can define the concept of a tetrad. This definition makes heavy use of the duality between $\Delta$ and $\Delta^*$. To describe the relation between tetrad and co–tetrad, it is, in fact, convenient to formulate everything in terms of the dual complex $\Delta^*$. Each 4–simplex $\sigma$ is dual to a vertex $v$ of $\Delta^*$, i.e. $\sigma = v^*$. By deleting a vertex $p$ in $\sigma$, we obtain a tetrahedron $\tau$. This tetrahedron $\tau$ is, in turn, dual to an edge $e$. Thus, the choice of a 4–simplex $\sigma$ and a vertex $p \subset \sigma$ defines an edge $e$ at the dual vertex $v$. Conversely, a pair $(v, e)$ can be used to label a vertex $p$ of the triangulation. Two different pairs $(v, e_1)$ and $(v', e'_1)$ correspond to the same vertex provided that 1) $(v, v') = e$ is an edge of $\Delta^*$ and that 2) $(e_1, e, e'_1)$ are consecutive edges in the boundary of a face of $\Delta^*$.

Since vertices of the triangulation correspond to pairs $(v, e_1)$, edges $\ell = [p_1p_2] \subset \sigma$ of $\Delta$ correspond to triples $(v, e_1, e_2)$. We can use this to translate the notation for the co–tetrad to the dual complex: instead of denoting the co–tetrad by $E_\ell(v)$, we can write it as $E_{e_1e_2}(v)$.

In this notation, the defining relations for the co–tetrad appear as follows:

$$E_{ee'}(v) = -E_{e'e}(v), \quad E_{e_1e_2}(v) + E_{e_2e_3}(v) + E_{e_3e_1}(v) = 0.$$

Similarly, the equation for the spin connection becomes

$$\Omega_e E_{e_1e_2}(v) = E_{e_1'e_2'}(v'),$$

where $e = (v v')$ is an edge of $\Delta^*$ and $(e_i, e'_i)_{i=1,2}$ are pairs of edges such that $(e_i, e, e'_i)$ are consecutive edges in the boundary of a face. Note that there are always four such pairs for a given edge $e$.

When stating relations between co–tetrad and tetrad, it is also convenient to define an orientation for each 4–simplex. By definition, a local orientation of $\Delta$ is a choice of $\mathbb{Z}_2$–ordering of vertices for each 4-simplex $\sigma$. Such an ordering is represented by tuples $[p_1, \cdots, p_5]$. Two $\mathbb{Z}_2$–orderings that differ by an even permutation are by definition equivalent. Two $\mathbb{Z}_2$–orderings that differ by an odd permutation are said to be opposite and we write $[p_1, p_2 \cdots, p_5] = -[p_2, p_1 \cdots, p_5]$. By duality it is clear that a local orientation is equivalent to a choice of $\mathbb{Z}_2$–ordering $[e_1, \cdots, e_5]$ of edges of $\Delta^*$ meeting at $v$. With this orientation we can also define a correspondence between edges $e_1$ and oriented tetrahedra $[p_2, \cdots, p_5]$.

Given a choice of local orientation of $\Delta$, one says that two neighboring 4–simplices $\sigma, \sigma'$ that share a tetrahedron $\tau$ are consistently oriented, if the orientation of $\tau$ induced
from $\sigma$ is opposite to the one induced from $\sigma'$. Namely, if $\sigma = [p_0, p_1, \cdots, p_4]$ and $\sigma' = [-p_0', p_1, \cdots, p_4]$, they induce opposite orientations on the common tetrahedron $\tau = [p_1, \cdots, p_4]$ and are therefore consistently oriented. The triangulation $\Delta$ is said to be orientable when it is possible to choose the local orientations such that they are consistent for every pair of neighboring 4–simplices. Such a choice of consistent local orientations is called a global orientation.

From now on and in the rest of the paper we assume that we work with an orientable triangulation and with a fixed global orientation.

**Definition VI.3** For a given non–degenerate co–tetrad $E$ on $\Delta$, the associated tetrad $U$ is an assignment of vectors $U_e(v) \in \mathbb{R}^4$ to each vertex $v$ and (unoriented) edge $e \supset v$ such that

$$U_{e'I}(v)E_{e'e}(v) = \delta_{e'e} - \delta_{e'I}$$

(63)

for all $e', e'' \supset v$.

These conditions specify the tetrad $U$ uniquely, as we show in appendix $\text{A}$. The orthogonality relation (63) is the discrete counterpart of the equation $E_{\mu I}E_{\nu I} = \delta_{\mu \nu}$ in the continuum.

Based on (63), we can derive a number of useful identities satisfied by a tetrad:

**Proposition VI.4** At any vertex $v \subset \Delta^*$, the tetrad vectors $U_e(v)$ close, i.e.

$$\sum_{e \supset v} U_e(v) = 0.$$  

(64)

For a tuple $[e_1 \cdots e_5]$ of edges at $v$, we can express the discrete tetrad explicitly in terms of the discrete co–tetrad and vice versa:

$$U_{e_2}(v) = \frac{1}{V_4(v)} \star (E_{e_3e_1}(v) \wedge E_{e_4e_1}(v) \wedge E_{e_5e_1}(v))$$

(65)

and

$$E_{e_2e_1}(v) = V_4(v) \star (U_{e_3}(v) \wedge U_{e_4}(v) \wedge U_{e_5}(v)),$$

(66)

where $V_4(v)/4!$ is the oriented volume of the 4–simplex spanned by the co–tetrad vectors:

$$V_4(v) = \det (E_{e_2e_1}(v), \ldots, E_{e_5e_1}(v)).$$

(67)

For bivectors, one has the relation

$$\star (E_{e_1e_2}(v) \wedge E_{e_2e_1}(v)) = V_4(v) (U_{e_4}(v) \wedge U_{e_5}(v)).$$

(68)

The norm of $U_e$ is proportional to the volume $V_3(e)/3!$ of the tetrahedron orthogonal to $U_e$:

$$|U_e(v)| = \frac{V_3(e)}{V_4(v)}.$$  

(69)

The determinant of the tetrad vectors equals the inverse of $V_4(v)$:

$$\frac{1}{V_4(v)} = \det (U_{e_2}(v), \ldots, U_{e_5}(v)).$$

(70)

In this proposition we have set $\star (E_1 \wedge \cdots \wedge E_n)_{t_1 \cdots t_4} \equiv \epsilon_{t_1 \cdots t_4} E_{t_5}^{I_5} \cdots E_{t_4}^{I_4}$. These statements are proven in appendix $\text{A}$.
**VII. SOLUTIONS**

With the help of the previous definitions, we will now determine the solutions to the equations (51), the simplicity constraints (48) and the non–degeneracy condition (52). For the proofs it is practical to denote the oriented wedge \((e f)\) by an ordered pair of edges \((ee')\) which meet at \(v\). The order \((ee')\) refers to the fact that \(e\) and \(e'\) are consecutive w.r.t. the orientation of the face. Note that the interior closure constraints \(X_{ef}(v) = X_{e'f}(v)\) mean that there is only one bivector per face \(f\) and vertex \(v\). Hence we can denote the bivectors by \(X_{ee'}(v) \equiv X_{ef}(v) = X_{e'f}(v)\).

**Proposition VII.1** Let \((j_f, n_{ef}, u_e, g_{ev}, h_{ef})\) be a configuration that solves eqns. (51), with the bivectors defined by the simplicity condition (47). Then, there exists a co–tetrad \(E\) such that for any vertex \(v\) and tuple \([e_1 \ldots e_5]\) of edges at \(v\)

\[
X_{e_1 e_5}(v) = \epsilon \star (E_{e_1 e_2}(v) \land E_{e_2 e_3}(v)).
\]

The factor \(\epsilon\) is a global sign, and the 4–volume \(V_4(v)\) is given by equation (64). This co–tetrad is unique up to inversions \(E_\ell(v) \rightarrow -E_\ell(v), \ell \subset v^*\).

Equivalently, the bivectors can be expressed by the associated tetrad \(U\), namely,

\[
X_{ee'}(v) = \epsilon V_4(v) (U_e(v) \land U_{e'}(v))
\]

for any pair of edges \(e, e' \supset v\).

Given this co–tetrad \(E\) and tetrad \(U\), the variables \((j_f, n_{ef}, u_e, g_{ev})\) are determined as follows: the spin \(j_f\) is equal to the norm of the bivector \(\star X_{ef}(v)\), and hence Regge–like. The group elements \(g_{v'v} = g_{v\epsilon} g_{ev}\) are, up to signs \(\epsilon_v\), equal to the spin connection for the co–tetrad \(E\), i.e.

\[
g_{v'v} = \epsilon_v \Omega_{v'v}, \quad \epsilon_v = \pm 1.
\]

For a given choice of the holonomy \(g_{ev}\) on the half–edge \(ev\), the group element \(u_e\) is determined, up to sign, by

\[
u_e = \frac{\pm 1}{|U_e(v)|} \left( (g_{ev}U_e(v))^0 \mathbb{1} + i (g_{ev}U_e(v))^i \sigma_i \right).
\]

The group element \(n_{ef}\) is fixed, up to a \(U(1)\) subgroup, by

\[
n_{ef} \sigma_3 n_{ef}^{-1} = N_{ef} \sigma_i,
\]

where for \(f = (ee')\)

\[
j_f N_{ef}^i = V_4(v) (g_{ev}) U_e(v) \land U_{e'}(v))^+\sigma_i.
\]

Conversely, every non–degenerate co–tetrad \(E\) and spin connection \(\Omega\) give rise to a solution via the formulas (71), (73), (74), and (75).

**Proof** Let us first consider two consecutive edges \(e\) and \(e'\) such that \(f = (ee')\). The simplicity condition \((\star X_{ef}(v)) \cdot \hat{U}_e(v) = 0\) implies that there exists a 4–vector \(N_{ef}(v)\) such that \(X_{ef}(v) = \hat{U}_e(v) \land N_{ef}(v)\). Similarly there exists another vector \(N_{ef}(v)\) such that \(X_{e'f}(v) = \hat{U}_{e'}(v) \land N_{ef}(v)\). The interior closure constraint \(X_{ef}(v) = X_{e'f}(v) \equiv X_f(v)\) requires that \(U_{e'}(v)\) belongs to the plane spanned by \(U_e(v)\) and \(N_{ef}(v)\), so there exist coefficients \(a_{ef}, b_{ef}\) such that

\[
\hat{U}_{e'}(v) = a_{ef} N_{ef}(v) + b_{ef} \hat{U}_e(v).
\]
If $a_{ef} = 0$, this means that $\hat{U}_e(v) = \hat{U}_e(v)$, since $\hat{U}$ are normalized vectors. This is excluded by our condition of non–degeneracy, since one would have $X_{ef} X_{ef}^\prime = X_{ef} X_{ef}^\prime = 0$ if $f_2 = (e e_2)$ and $f_2 = (e e_2')$. Denoting $\alpha_{ee'} \equiv a_{ef}^{-1}$ one therefore has $N_{ef} = \alpha_{ee'} \hat{U}_e - \alpha_{ee'} b_{ef} \hat{U}_e$ and hence

\[ X_{ee'}(v) = \alpha_{ee'}(v) \left( \hat{U}_e(v) \wedge \hat{U}_e'(v) \right). \tag{78} \]

It follows from this expression and the non–degeneracy condition \[52\] that the vectors $\hat{U}_e(v), e \supset v$, span a 4–dimensional space. As shown in appendix \[B1\] the exterior closure constraints

\[ \sum f \geq e \epsilon_{ef} X_f(v) = 0, \tag{79} \]

imply the factorization $\alpha_{ee'} = \epsilon(v) \alpha_e(v) \alpha_{ee'}(v)$, where $\epsilon(v) = \pm 1$ and $\alpha_e(v)$ are real numbers, independent of the orientation of $e$, such that

\[ \sum_{e \supset v} \alpha_e(v) \hat{U}_e(v) = 0 \quad \text{and} \quad j_f^2 = \alpha_e^2(v) \alpha_{ee'}^2(v) \sin^2 \theta_{ee'}(v). \tag{80} \]

The angle $\theta_{ee'}(v)$ is defined by $\cos \theta_{ee'}(v) = \hat{U}_e(v) \cdot \hat{U}_e'(v)$. These conditions only admit a solution if there exists a discrete, geometrical 4–simplex (i.e. a set of edge lengths $\ell(v)$) such that $j_f$ and $\theta_{ee'}$ are the areas and dihedral angles in this 4–simplex. In this case, $|\alpha_e(v)|$ is uniquely determined by the spins $j_f$ and the unit vectors $\hat{U}_e(v)$. The $\alpha_e(v)$ themselves are only fixed up to an overall sign, i.e. if $\alpha_e, e \supset v$, solves \[80\], then $\epsilon_v \alpha_v(v), \epsilon_v = \pm 1$, is a solution as well.

Given the ordering $e_1, \ldots, e_5$ of edges at $v$, we then define

\[ V_4(v) \equiv \det \left( \alpha_{e_2} \hat{U}_e(v), \ldots, \alpha_{e_5} \hat{U}_e(v) \right) \quad \text{and} \quad U_e(v) \equiv \frac{\alpha_e(v)}{\sqrt{|V_4|}} \hat{U}_e(v). \tag{81} \]

These vectors have the property that

\[ \sum_{e \supset v} U_e(v) = 0 \quad \text{and} \quad X_{ee'}(v) = \epsilon(v) V_4(v) (U_e(v) \wedge U_e'(v)), \tag{82} \]

where $\epsilon(v) = \pm 1$. Thus, the $U_e(v)$ define tetrad vectors for the 4–simplex dual to $v$, and we can use formula \[66\] to specify corresponding co–tetrad vectors $E_\ell(v)$.

Next we need to analyze the equations that relate neighboring 4–simplices $v$ and $v'$, connected by the edge $e = (vv')$:

\[ g_{ee'} \hat{U}_e(v') = \hat{U}_e(v), \quad g_{ee'} \triangleright X_f(v') = X_f(v). \tag{83} \]

The first condition leads to $g_{ee'} U_e(v')/|U_e(v')| = \tilde{\epsilon}_e U_e(v)/|U_e(v)|$, where $\tilde{\epsilon}_e \equiv \sgn \alpha_e(v) \sgn \alpha_e(v') = \pm 1$. By combining this with the second condition we find that for every edge $\ell$ of the tetrahedron dual to $e = (vv')$ (see appendix \[B2\])

\[ g_{ee'} E_\ell(v') = \epsilon_e E_\ell(v), \tag{84} \]

with the sign $\epsilon_e \equiv \tilde{\epsilon}_e \sgn(V_4(v) V_4(v')) = \pm 1$. We see therefore that the vectors $E_\ell(v)$ satisfy the compatibility condition (iii) in the definition of a co–tetrad, and hence they specify a
co–tetrad on the entire simplicial complex. Equation (84) shows furthermore that \( g_{vv'} \) is, up to the sign \( \epsilon_e \), equal to the spin connection \( \Omega_{vv'} \) associated with the co–tetrad \( E \):

\[
g_{vv'} = \epsilon_e \Omega_{vv'}.
\]  

(85)

In appendix B.2 we also derive that the signs \( \epsilon(v) \) in eq. (82) are constant, i.e. \( \epsilon(v) = \epsilon(v') \) for neighbouring vertices \( v \) and \( v' \).

The aforementioned ambiguity in the factors \( \alpha_e(v) \) is transported into the co–tetrad and tetrad: for a given solution \( (j_f, n_{ef}, u_e, g_{ev}, h_{ef}) \), the tetrad and co–tetrad are fixed up to a reversal of edges in the geometrical 4–simplices: i.e. up to replacing \((E_\ell(v), U_\ell(v)) \rightarrow (-E_\ell(v), -U_\ell(v))\) for all \( \ell \subset v^* \), \( e \supset v \).

If we start, conversely, from a co–tetrad \( E \) and its tetrad \( U \), it is clear that equations (82) and (85) define bivectors and connections which solve the equations (51). The associated spins \( j_f \) and group variables \( u_e \) and \( n_{ef} \) follow directly from the definitions (41) and (45).

\[\blacksquare\]

A. Determination of \( h \)

So far we have determined \((j_f, u_e, n_{ef}, g_{ev})\) in terms of a co–tetrad \( E \) and signs \( \epsilon \) and \( \epsilon_e \equiv e^{\text{int}e} \). In order to complete the characterization of the solution, we also need to determine \( h_{ef} \). This is done in the following

**Proposition VII.2** For a non–degenerate co–tetrad \( E \) and a choice of global sign \( \epsilon \) and edge signs \( \epsilon_e \), the holonomy of \( g_e = \epsilon_e \Omega_e \) around a face \( f \) with starting point \( v \) has the form

\[
G_f(v) = e^{\epsilon \Theta_f \hat{X}_f(v)} e^{\pi \sum_{e \subset f} n_e} \hat{X}_f(v),
\]

(86)

where the bivector \( X_f(v) \) is determined by \( E \) as in equation (71) and \( \hat{X}_f = X_f/|X_f| \). In this equation the bivector is treated as an antisymmetric map acting on \( \mathbb{R}^4 \) and we take an exponential of this map.

In the corresponding solution \((j_f, u_e, n_{ef}, g_{ev}, h_{ef})\) of eqns. (51), the group elements \( h_{ef} \) are uniquely determined, up to gauge transformations, by a choice of angles \((\theta_{ef}, \tilde{\theta}_{ef})\) for each wedge: these angles are subject to the conditions

\[
\sum_{e \subset f} \theta_{ef} = \epsilon \Theta_f, \quad \sum_{e \subset f} \tilde{\theta}_{ef} = \pi \sum_{e \subset f} n_e.
\]

(87)

where \( \Theta_f \) is the deficit angle of the spin connection. The associated wedge holonomies equal

\[
G_{ef}(v) = e^{\theta_{ef} \hat{X}_f(v)} e^{\tilde{\theta}_{ef} \hat{X}_f(v)}
\]

(88)

**Proof** In order to do the analysis it is convenient to change the frame and base all our quantities at the center of the face \( f \) (see Fig. 4). That is, we define

\[
X_{ef}(f) \equiv h_{ef} \triangleright X_e, \quad G_{ef}(f) \equiv h_{ef} G_e h_{ef} = h_{fe} g_{ee} g_{ve} h_{ef}.
\]

(89)

It follows from the equations (51) that \( X_{ef}(f) \equiv X_f(f) \) is independent of the wedge and that \( G_{ef}(f) \triangleright X_f(f) = X_f(f) \). The latter implies that

\[
G_{ef}(f) = e^{\theta_{ef} \hat{X}_f(f)} e^{\tilde{\theta}_{ef} \hat{X}_f(f)}
\]

(90)
Figure 4: The wedge holonomies $G_{e,f}(f)$ have their starting and end point at the center of the face.

where $\hat{X}_f(f) = X_f(f)/|X_f(f)|$. The angles $\theta_{ef}$ and $\tilde{\theta}_{ef}$ have to satisfy constraints, as we will show now.

First we remark that the holonomy around the face $f$ can be written as a product of wedge holonomies

$$G_f(f) \equiv G_{e_1 f}(f) \cdots G_{e_n f}(f) = (h_{fe_1 g_{e_1 v}}) G_f(v) (h_{f e_1 g_{e_1 v}})^{-1}.$$  \hspace{1cm} (91)

On the right–hand side $G_f(v)$ is the face holonomy based at the vertex $v$. We have seen that the connection of a solution satisfies $g_e = \epsilon_g \Omega_e$, where $\Omega$ is the spin connection and $\epsilon$ is an arbitrary sign. The defining property of the spin connection is that $\Omega_{vv'} E_\ell(v') = E_\ell(v)$ for all edges $\ell$ in the tetrahedron dual to $e = (vv')$.

As a result, the holonomy around the face $f$ preserves the co–tetrads associated with the triangle dual to $f$. More precisely, let us suppose that $\partial f^* = \ell_1 + \ell_2 + \ell_3$. Then, the on-shell holonomy fulfills

$$G_f(v) E_\ell_i(v) = \left( \prod_{\ell \subset f} \epsilon_\ell \right) E_\ell_i(v), \quad i = 1,2,3.$$  \hspace{1cm} (92)

As we have shown earlier, the bivector $X_f(v)$ is on-shell given by

$$X_f(v) = \epsilon \ast (E_{\ell_1}(v) \wedge E_{\ell_2}(v)).$$  \hspace{1cm} (93)

Hence the condition (92) can be equivalently expressed by

$$G_f(v) = e^{\epsilon \Theta_f \hat{X}_f(v)} e^{\pi (\sum_{\ell \subset f} n_\ell) \ast \hat{X}_f(v)}$$  \hspace{1cm} (94)

where $\epsilon = e^{in_\ell}$ and $\hat{X}_f(v) = X_f(v)/|X_f(v)|$. The angle $\Theta_f$ is the deficit angle of the spin connection w.r.t. the face $f$. Combining this result with eq. (91) one obtains that

$$\sum_{\ell \subset f} \theta_{ef} = \epsilon \Theta_f, \quad \sum_{\ell \subset f} \tilde{\theta}_{ef} = \pi \sum_{\ell \subset f} n_\ell.$$  \hspace{1cm} (95)

For a given tetrad $U$, the associated spin connection $\Omega$, and a choice of signs $\epsilon_e$, the angles $\theta_{ef}$ and $\tilde{\theta}_{ef}$ have to meet the constraint (95). Once such angles $(\theta_{ef}, \tilde{\theta}_{ef})$ are selected, we can solve for $h_{ef}$ recursively. For this, let us set $h_i \equiv h_{e_i f}$ and define

$$G_i(\theta_{e_i f}, \tilde{\theta}_{e_i f}) \equiv e^{\theta_{e_i f} X_f(v_i)} e^{\tilde{\theta}_{e_i f} \ast X_f(v_i)}.$$  \hspace{1cm} (96)

The equations

$$G_{e_i f}(v_i) = G_i(\theta_{e_i f}, \tilde{\theta}_{e_i f})$$  \hspace{1cm} (97)
can be recursively solved by setting
\[ h_{i+1} = g_{e_{i+1}v_i}G_i g_{v_i}h_i, \quad h_1 = h_f, \]  
where \( h_f \) is an arbitrary initial value. This solution is consistent, since
\[ h_1 \equiv h_{n+1} = g_{e_1v_n}G_n g_{v_nv_{n-1}}G_{n-1} \cdots g_{v_1v_1}G_1 g_{v_1}h_1 \]
\begin{align*}
&= g_{e_1v_n}G_n (g_{v_nv_{n-1}}G_{n-1}g_{v_{n-1}v_n}) \cdots (g_{v_1v_1}G_1g_{v_1}G_0) g_{v_1}h_1 \\
&= g_{e_1v_n}G_f(v_n) G_f^{-1}(v_n) g_{v_1}h_1 = h_1. \end{align*}

In the third equality, we used that \( X_{ef}(v') = g_{v'n}X_{ef}(v)g_{v'}^{-1} \). Note that the group element \( h_f \) can be fixed to the identity by a gauge transformation at the face center. This shows that, up to gauge, the elements \( h_{ef} \) are determined by the choice of the angles \( \theta_{ef}, \tilde{\theta}_{ef} \).

**VIII. SEMICLASSICAL APPROXIMATION OF EFFECTIVE AMPLITUDE**

**A. Evaluation of action**

In the previous section, we have seen that solutions of the equations (48, 51, 52) exist only if the set \( j_f \) is Regge–like and, up to gauge transformation, they are uniquely determined by a choice of a discrete metric (coming from a co–tetrad \( E \)), of a global sign \( \epsilon \), of edge signs \( \epsilon_e \) and a choice of \( U(1) \) wedge angles \( (\theta_{ef}, \tilde{\theta}_{ef}) \) subject to (95).

**Proposition VIII.1** Given a solution characterized by the data \( (U_e, \epsilon, \epsilon_e, \theta_{ef}, \tilde{\theta}_{ef}) \), the on–shell action is independent of \( (\theta_{ef}, \tilde{\theta}_{ef}) \) and given by
\[
e^{S^\gamma(U_e, \epsilon, \epsilon_e)} = \begin{cases} 
\left. e^{i \sum_j A_j \Theta_j} \prod_{e} \epsilon_e^{J_e}, \quad \gamma > 0, \right. \\
\prod_{e} \epsilon_e^{J_e}, \quad \gamma = 0,
\end{cases}
\]

where \( A_j = (\gamma^+ + \gamma^-)j_f \) is the area of \( f \) in Planck units \( (8\pi\hbar G = 1) \) for \( \gamma > 0 \) (see eq. (101)), \( \Theta_j \) is the deficit angle of the spin connection, and \( J_e \equiv (\gamma^+ - \gamma^-) \sum_{f \supset e} j_f \).

Before giving the proof a few remarks are in order. Firstly, in the EPR model the on–shell evaluation is trivial, in agreement with the claim that the EPR model is a quantization of the topological sector. Moreover, for general \( \gamma \), the dependence on the Immirzi parameter drops out from the on–shell action.

Secondly, when evaluating the semiclassical asymptotics of the effective amplitude \( W^\gamma_\mathcal{A}(j_f) \), one has to sum over all classical configurations and hence over \( \epsilon_e \). This sum gives zero unless \( J_e \) is an even integer. It is interesting to note that when \( \gamma^\pm \) are both odd integers the same condition arises in the spin foam model.

To see this, note that if \( \gamma^\pm \) are both odd, the condition that the weight projects down to a function of \( \text{SO}(4) \) (i.e. \( (\gamma^+ - \gamma^-)j_f \in \mathbb{Z} \)) is satisfied without any restriction on \( j_f \), since \( (\gamma^+ - \gamma^-) \) is even. Moreover, the amplitudes in the spin foam model require that the invariant \( \text{SU}(2) \) subspace \( \text{Inv} \left( \otimes_{f \supset e} V_{j_f}^{\pm} \right) \) is non–trivial. This is the case if and only if \( \sum f j_f^\pm \) is integer–valued. Therefore, \( \sum f j_f \) is integer–valued and \( J_e \) is even.
Proof As shown in the previous section, the wedge holonomy has the form

\[ G_{\epsilon_f}(v) = e^{\theta_{\epsilon_f} \hat{X}_f(v) e^{\tilde{\theta}_{\epsilon_f} \hat{X}_f(v)}}. \]  

(102)

where \( \hat{X}_f(v) = \frac{X_f(v)}{|X_f(v)|} \). In the \( \operatorname{SU}(2) \times \operatorname{SU}(2) \) notation this condition reads

\[ G_{\epsilon_f}^\pm(v) = e^{i(\theta_{\epsilon_f} \pm \tilde{\theta}_{\epsilon_f}) X_f^\pm(v)}. \]  

(103)

Recall also that the bivectors \( X_f^\gamma \) and \( X_f^\pm \) are related by

\[ X_f^\gamma = \gamma X_f^\pm, \quad |X_f^\pm| = j_f. \]  

(104)

We insert this into the action, observing that \( X_f^\gamma / |X_f^\gamma| = \gamma / |\gamma| \hat{X}_f^\pm \), and obtain

\[
S = \sum_f \left\{ 2|\gamma^+|j_f \sum_{e \subset f} \ln \left( \operatorname{tr} \left[ \frac{1}{2} \left( 1 + \frac{\gamma^+ X_f^+}{|\gamma^+ X_f^+|} \right) G_{\epsilon_f}^+ \right] \right) \right. \\
+ 2|\gamma^-|j_f \sum_{e \subset f} \ln \left( \operatorname{tr} \left[ \frac{1}{2} \left( 1 + \frac{\gamma^- X_f^-}{|\gamma^- X_f^-|} \right) G_{\epsilon_f}^- \right] \right) \right\} \\
= \sum_f \left\{ i\gamma^+ j_f \sum_{e \subset f} (\theta_{\epsilon_f} + \tilde{\theta}_{\epsilon_f}) + i\gamma^- j_f \sum_{e \subset f} (\theta_{\epsilon_f} - \tilde{\theta}_{\epsilon_f}) \right\} \\
= i\epsilon \sum_f (\gamma^+ + \gamma^-) j_f \Theta_f + i\pi (\gamma^+ - \gamma^-) \sum_e n_e \left( \sum_{f \supset e} j_f \right). \\
\]

(105)

(106)

(107)

(108)

B. Asymptotic approximation

In order to arrive at our final result we need to determine the asymptotic approximation of the effective amplitude (14) for large spins. As shown, this partition function can be expressed as an integral

\[ I_N = \int dx \ e^{-NS(x)} \]  

(109)

over a set of compact variables \( x \). In our case the variables are group elements, so \( S \) can be taken to be a periodic function. It is customary to restrict the study of this type of integral to the case, where \( S \) is pure imaginary and use the stationary phase approximation. It is less well-know, but nevertheless true, that the stationary phase method is valid when \( S \) is a complex function, provided \( \operatorname{Re}(S) \geq 0 \) (see \[39\] Chapter 7.7). In this reference, it is shown that when \( S \) is \( C^\infty \) and if \( |S'|^2 + \operatorname{Re}(S) \) is always strictly positive (with \( |S'|^2 = \partial_\mu \bar{S} \partial^\mu S \)), then the integral is exponentially small. More precisely, if \( S \) is \( C^{k+1} \) there exists a constant \( C \) such that

\[ I_N \leq C \frac{1}{N^k \min (|S'|^2 + \operatorname{Re}(S)))^k}. \]  

(110)
This shows that the integral is exponentially suppressed as long as \( S' \neq 0 \) or \( \text{Re}(S) > 0 \).

Therefore, the dominant contribution comes from configurations that are both stationary points of the action \( S \), and absolute minima of its real part \[39\]. One says that \( x_c \) is a generalized critical point if \(|S'|^2(x_c) + \text{Re}(S)(x_c) = 0\). In case there are such points, we have the asymptotic approximation

\[
I_N \sim \sum_{x_c} \left( \frac{2\pi}{N} \right)^\frac{r}{2} \frac{e^{-NS(x_c)}}{(\det_r(H'))^\frac{1}{2}}.
\]

where \( x_c \) are the stationary points of \( S \), \( r \) is the rank of the Hessian \( H = \partial_i \partial_j S(x_c) \), \( H' \) is its invertible restriction on \( \ker(H) \), and \( \sigma \) is the signature of \( H' \). When the stationary points are not isolated, one has an integration over a submanifold of stationary points whose dimension equals the dimension of the kernel \( \ker(H) \). Note that for a generalized critical point the action \( S(x_c) \) is purely imaginary.

In our case, we have shown that the effective amplitude has no generalized critical points if \( j_f \) is not Regge–like. Then, the previous theorem implies that the amplitude is exponentially suppressed. When \( j_f \) is Regge–like, there is, up to gauge–transformations, a discrete set of solutions labelled by \((E(j_f), \epsilon_e, \epsilon)\). This result is only valid if one restricts the integration to non–degenerate configurations \(|X \land X| > \alpha\), with \( \alpha \) an arbitrary small positive number.

When applied to the integral \[114\], this gives us that

\[
W_{\Delta}^{ND} \gamma(Nj_f) \sim \frac{c_D(j_f)}{\sqrt{N}} \sum_{\epsilon,e} \exp(NS^2_{\Delta}(E(j_f), \epsilon_e)) = \frac{c_D(j_f)}{\sqrt{N}} \exp(NS_R + \text{c.c.}) \, ,
\]

if the set \( j_f \) is Regge–like and all \( J_e \) even. Otherwise the amplitude is exponentially suppressed. If there are several tetrad fields \( E(j_f) \) that correspond to a given set \((j_f)_f\) one should also sum over them.

While we have not computed the Hessian, our analysis can give us explicit information about its rank \( r_{\Delta} \). In our case, the space of integration is the space of \((u_e, n_{ef}, g_{ex}, h_{ef})\) which is of dimension \( D = 3E + 2W + 6 \times 2E + 6W \). Here, \( E, W, F, V \) denote the number of edges, wedges, faces and vertices of \( \Delta^* \). As we have seen, the space of solutions is labelled by gauge transformations \((\lambda_e, \lambda_f, \lambda_v)\) and two \( U(1) \) angles \((\theta_{ef}, \theta_{ef})\) subject to one constraint per face. Thus, the dimension of the kernel of \( H \) is \( d = 6E + 6F + 6V + 2W - 2F \). We can then compute the rank to be

\[
r_{\Delta} \equiv D - d = 33E - 6V - 4F \, ,
\]

using the fact that \( W = 4E = 10V \).

### C. Degenerate sector

In order to complete our analysis of the effective amplitude and show its asymptotic Regge-like behavior, we have restricted the summation to non–degenerate configurations.

One could wonder whether the degenerate contributions are dominant or subdominant in this semiclassical limit\[11\]. This amounts to asking which sector has the most degenerate

\[11\] For instance, in the analysis of the 10j–symbol it was shown that the degenerate configurations were non–oscillatory, but dominant \[32, 11\]
Hessian, since the amplitude is suppressed by $1/N^{1/2}$ to the power of the rank of the Hessian. Thus, it is the sector with the higher-dimensional space of solutions (higher dimensional phase space) that dominates, or in other words the one with higher entropy.

In order to get an idea of the dimension of the space of solutions in both sectors, let us look at the solution of the simplicity and closure constraints at a single vertex. In the non-degenerate sector, it is given by

$$X_{ij} = V U_i \wedge U_j, \quad \sum_i U_i = 0.$$  

(114)

This describes 10 rotationally invariant degree of freedom, counting $5 \times 4$ $U$'s subject to 4 independent constraints minus 6 rotations. These 10 degrees of freedom match the 10 area spins.

On the other hand of the spectrum we can look at the most degenerate contribution, where all the wedge products of $X$'s are zero. In this case, the most degenerate solution is given by

$$X_{ij} = U \wedge N_{ij}, \quad \sum_i N_{ij} = 0, \quad U^2 = 1, \quad N_{ij} \cdot U = 0.$$  

(115)

Due to the last equation, the $N_{ij}$ are, in effect, 3-dimensional vectors. Now, the counting of rotationally invariant degrees of freedom gives 15, 5 more degrees of freedom per vertex than in the non-degenerate case. Indeed, we have 3 $U$'s plus $3 \times 10$ $N$'s minus $4 \times 3$ independent constraints minus 6 rotations.

For each $i$ we can reconstruct a geometrical tetrahedron from $N_{ij}, j \neq i$, for which $N_{ij}$ are the area normal vectors. Hence the degenerate solution determines 5 tetrahedra. These 5 tetrahedra are “glued together” in the sense that the faces shared by tetrahedra have the same area. However, they do not form a 4-simplex. In a 4-simplex the volume of each tetrahedron is fixed by the area of the faces, while in the degenerate case the 5 3-volumes are independent variables and thus increase the phase space dimension.

This argument indicates that the phase space dimension of the degenerate configurations is higher than the non-degenerate one by at most 5 times the number of vertices. This result bears some similarity with the recent canonical analysis of [40], where it was pointed out that the phase space dimension associated with spin networks is higher than the corresponding dimension for discrete geometries. Our reasoning suggests that this extra phase space corresponds to 4d degenerate solutions.

This analysis is suggestive, but not complete, since one would need to analyze the gluing equations and the other degenerate sectors. However, it leads one to suspect that the degenerate configuration dominate the effective amplitude in the semiclassical limit if they are included. In this case, the non-degeneracy requirement would be necessary. One challenge is to be able to formulate this requirement at the level of the spin foam model and not only in the path integral representation. Another possibility is that the degenerate contributions are suppressed when we couple the effective amplitude to a semiclassical boundary state. This is a scenario that has been realized in the case of the $10j$-symbol [8].

IX. SUMMARY AND DISCUSSION

In this work, we have studied the semiclassical properties of the Riemannian spin foam models $\text{FK}_\gamma$. We have shown that, in the semi-classical limit, where all the bulk spins are
rescaled, the amplitude converges rapidly towards the exponential of \( i \) times the Regge action, provided the face’s spins can be understood as coming from a discrete geometry. When the spins do not arise from a discrete geometry, the spin foam amplitude is exponentially suppressed.

There are several remarks to be made about this result: First, it is shown for an arbitrary triangulation and not only for the amplitude associated with a 4-simplex. This should be contrasted with what was achieved in the context of the Barrett–Crane model, where only one or two 4-simplices were considered. An extension of these results to more 4-simplices seemed increasingly complicated (see [42] for a very recent discussion of this in the context of Regge calculus). The second fact to be noticed is that the Immirzi dependence drops out in the semiclassical limit. This should indeed be the case, since nothing depends on the Immirzi parameter at the classical level (except when it is zero). Nevertheless it was not obvious from the original definition of the amplitude that this would happen. Also, the results shown here depend heavily on the details of the implementation of the simplicity constraints: they rely on the specific choice of the measure \( D_{\gamma}^{j,k} \) (see eq. (3)). For instance, we cannot extend our results to the ELPR model for \( \gamma > 1 \) which includes the Barrett–Crane model for \( \gamma = \infty \). A fourth point concerns the fact that in spin foam models areas are the natural variables, whereas one needs access to edge lengths in order to have a discrete geometry. To formulate constraints on areas, so that they correspond to discrete geometries, has been so far one of the conundrums faced in the LQG/spin foam approach. Several studies have been launched in order to tackle this problem (see for instance [33, 44, 45]), but the results show that performing this explicitly is an incredibly difficult algebraic task. What we find quite remarkable is that it is not necessary to answer this question analytically to get the proper semiclassical limit of a spin foam model. The spin foam model “knows” which set of areas does or does not arise from a 4d geometry and it naturally suppresses the non-geometric phase in the semiclassical limit.

These results provide considerable evidence in favor of the proposed spin foam amplitude as a valid amplitude for quantum gravity, in the sense that it reproduces expected semiclassical behavior. There is, however, more work to be done to fully confirm this picture.

First of all, in order to obtain this result we have to restrict the summation to non-degenerate configurations. We know how to implement this restriction in the path integral formulation, but not in terms of the spin foam model. As we have argued, this restriction may be important in order to get the correct semi-classical limit, but a deeper analysis is clearly required to establish this firmly.

More crucially, we have shown the semiclassical property of the bulk amplitude, where the bulk spins are fixed and uniformly rescaled to large values. That is, we have demonstrated the proper semiclassicality for certain histories that one should sum over in computing amplitudes. What we are ultimately interested in is the semiclassical property of the sum over amplitudes. Given a boundary spin network, we would like to sum over all spins in the interior compatible with the boundary spin network and show that the resulting amplitude gives an object that can be interpreted as the exponential of the Hamilton–Jacobi functional of a gravity action. Our result is a necessary condition for this to happen, but we have not shown that this is sufficient.

What would be required is that for given semiclassical boundary states peaked on large spins, the corresponding amplitude is peaked around large bulk spins as well; and that the semiclassical amplitude reduces effectively to a summation over discrete geometries with the Regge action. In a sense, one needs that the large spin limit and the integration over the
spins commute with each other. Whether this happens or not is not obvious: one might be worried, for instance, that the summation over spins is much less restricted than a summation over discrete geometries and that this will lead to stronger equations of motions. It might be, on the other hand, that the exponential suppression of non Regge–like configurations is strong enough to effectively reduce the summation to a sum over geometries. This is an important question that deserves to be studied further.

An obvious open problem is whether our results can be extended to the Lorentzian case. We expect that this is possible, however, it has not been shown yet whether the present Lorentzian models admit a nice action representation, which is needed for our analysis.

Moreover, our work does not address the question of the continuum limit of spin foam models. We have considered the semiclassical limit of discrete configurations on a fixed triangulation. One might want to take a continuum limit, where the number of boundary vertices of the spin network grows. It is not clear if such a limit commutes with the semiclassical limit taken here.

Despite all these open questions, we feel that the semiclassicality shown here opens the way towards new, exciting developments in the spin foam approach to quantum gravity.

Appendix A: RELATION BETWEEN CO–TETRAD AND TETRAD IN A 4–SIMPLEX

Based on the duality (63) between discrete tetrad and co–tetrad, we can prove a number of identities that are analogous to equations for the co–tetrad and tetrad in the continuum. Consider a vertex \(v\) in \(\Delta^*\) and label the vertices \(p \subset v^*\) (and corresponding dual edges \(e \supset v\)) by lowercase letters \(i, j, k \ldots = 1, \ldots, 5\). The tetrad and co–tetrad vectors \(U_{i}^e(v)\) and \(E_{ij}(v)\) are written as \(U^i\) and \(E_{ij}\). We denote \(R^4\)–indices by capital letters \(I, J, K\) etc.

**Proposition A.1** The equation

\[
U^i I E_{mk}^j = \delta^i_m - \delta^i_k.
\]

(A1)

determines a bijection between non–degenerate vectors \(E_{ij} \in R^4, i, j = 1, \ldots, 5\), satisfying

\[
E_{ij} + E_{ji} = 0, \quad E_{ij} + E_{jk} + E_{ki} = 0 \quad \forall i, j, k = 1, \ldots, 5,
\]

(A2)

and non–degenerate vectors \(U^i \in R^4, i = 1, \ldots, 5\), for which \(\sum_{i=1}^{5} U^i = 0\).

The map from \(E_{ij}\) to \(U^i\) is given by

\[
U^i = \frac{1}{3! V_4} \sum_{j_1, j_2, j_3} \varepsilon^{k_1j_1j_2j_3} \star (E_{j_1k} \wedge E_{j_2k} \wedge E_{j_3k}),
\]

(A3)
where $k$ is any vertex different from $i$. $U^i$ is independent of this choice thanks to the identity (A2). $V_4$ denotes the oriented volume of the $4$–parallelotope spanned by the co–tetrad vectors,

$$V_4 = \det (E_{21}, \ldots, E_{51}) ,$$

(A4)

and we have set

$$[\epsilon(E_1 \wedge \cdots \wedge E_n)]_{I_1 \ldots I_{4-n}} \equiv \epsilon_{I_1 \ldots I_{4-n}} E_{1}^{I_{5-n}} \cdots E_{n}^{I_4} .$$

(A5)

The norm of $U^i$ is proportional to the volume $V_3$ of the tetrahedron orthogonal to $U^i$:

$$|U^i| = \frac{V_3}{|V_4|} ,$$

(A6)

The inverse of $V_4$ equals the determinant of the $U$’s:

$$\frac{1}{V_4} = \det (U_{21}, \ldots, U_{51})$$

(A7)

The inverse map from $U$ to $E$ is specified by

$$E_{jk} = \frac{1}{3!} V_4 \sum_{i_1, i_2, i_3} \epsilon_{ij1i_2i_3} \epsilon (U^{i_1} \wedge U^{i_2} \wedge U^{i_3}) .$$

(A8)

More generally, the relation between $U$ and $E$ is given by

$$U^{i_1}_{I_1} \cdots U^{i_n}_{I_n} = \frac{1}{(4-n)!V_4} \sum_{j_1 \ldots j_{4-n}} \epsilon^{ki_1 \ldots i_n j_1 \ldots j_{4-n}} \epsilon (E_{j_1k} \cdots E_{j_{4-n}k})_{I_1 \ldots I_n} , \quad k \neq i_1, \ldots, i_n .$$

(A9)

The special cases $n = 1$ and $n = 3$ return equations (A3) and (A8) respectively. For $n = 2$ one obtains

$$V_4 U^i_{[I} U^j_{]I} = \sum_{m,n} \epsilon^{kijmn} \frac{1}{2} \epsilon^{IJ} \epsilon^{MN} E_{mk}^M E_{nk}^N , \quad k \neq i, j .$$

(A10)

**Proof** For the first part of the proof, let us assume the vectors $E_{ik}$ with property (A2) are given and that the $U_i$’s satisfy relation (A1). The identity (A3) is proven, like in the continuum, by contracting the left– and right–hand side with $E_{jk}$. That the $U_i$’s close follows directly from (A3). Formula (A6) can be derived by using (A3) and the relation between volume and Gram’s determinant. Identity (A7) follows from (A1) and the multiplication rule for determinants. By contraction and use of (A7), we also verify eq. (A8).

To demonstrate that the right–hand side is independent of $k \neq i$, it helps to regard the $E_{ik}$ as edge vectors of a $4$–simplex in $\mathbb{R}^4$. We can think of this $4$–simplex as the image of the $4$–simplex $\sigma \subset \Delta$ under an affine transformation. Let $P_1, \ldots, P_5 \in \mathbb{R}^4$ denote the images of the vertices $p_1, \ldots, p_5 \subset \sigma$. Then, the edge vectors are equal to

$$E_{ik} = P_i - P_k .$$

(A11)

Without loss of generality, we can assume that

$$\sum_{i=1}^5 P_i = 0 .$$

(A12)
Using this, we deduce that

\[ U^i = \frac{1}{3! V_4} \sum_{k,j_1,j_2,j_3} \epsilon^{kij} P_{j_1} \land P_{j_2} \land P_{j_3} , \quad \text{(A13)} \]

making the independence of \( k \neq i \) in (A3) manifest.

Conversely, suppose we have vectors \( U_i \) that close and that the \( E_{jk} \)'s fulfill relation (A1). We then define vectors

\[ P_j = \frac{1}{5 \cdot 3! V_4} \sum_{k,i_1,i_2,i_3} \epsilon_{kji_1i_2i_3} \star \left( U^{i_1} \land U^{i_2} \land U^{i_3} \right) \quad \text{(A14)} \]

and verify that

\[ E_{ik} = P_i - P_k . \quad \text{(A15)} \]

Hence the vectors \( E_{ik} \) close.

Relation (A9) is demonstrated by contracting with \( n \) \( E \)'s. \( \blacksquare \)

### Appendix B: RECONSTRUCTION OF 4–GEOMETRY

In this appendix, we complete the proof of proposition (VII.1). In the first part, we will derive that the bivectors \( X_f(v) \) arise from a geometric 4–simplex. A key step for this is that the factors \( \alpha_{ee'} \) in eq. (78) factorize. In the second part, we derive relations among tetrad vectors between neighbouring vertices, showing that the tetrad and co–tetrad vectors define a consistent discrete geometry on the simplicial complex. We will prove, in particular, that the sign factors \( \epsilon(v) \) in eq. (82) are the same for every vertex.

#### 1. Reconstruction of 4–simplex

Consider a vertex \( v \subset \Delta^* \) and the edges \( e_1, \ldots, e_5 \supset v \). To simplify formulas, we use the abbreviations \( X_{ij} \equiv X_{e_i e_j} \), \( U_i \equiv U_{e_i} \), and \( E_{ij} \equiv E_{e_i e_j} \).

**Proposition B.1** Let \( X_{ij} = -X_{ji}, i, j = 1, \ldots, 5 \), be non–degenerate bivectors (i.e. \( |X_{ij} \land X_{ki}| > 0 \)) which satisfy the simplicity and closure constraint

\[ X_{ij}^{IJ}(\hat{U}_i)_J = 0 , \quad \text{(B1)} \]

\[ \sum_{j \neq i} X_{ij} = 0 . \quad \text{(B2)} \]

Then, there are, modulo translations, precisely two 4–simplices whose area bivectors equal \( \star X_{ij} \) and they are related by a reversal of edge vectors. That is, there are exactly two sets of vectors \( E_{ij} \in \mathbb{R}^4, i, j = 1, \ldots, 5 \), obeying the closure condition (A2), such that

\[ X_{ij} = \epsilon \sum_{m,n} \frac{1}{2} \epsilon_{kijmn} \star (E_{mk} \land E_{nk}) , \quad k \neq i, j . \quad \text{(B3)} \]

The sign factor \( \epsilon \) is either 1 or \( -1 \) \( \forall i, j = 1, \ldots, 5 \). The two sets \( \{E_{ij}\} \) are related by the \( \text{SO}(4) \) transformation \( E_{ij} \rightarrow -E_{ij} \).
Proof} The simplicity constraints \((B1)\) imply that
\[
X_{ij} = \alpha_{ij} \hat{U}_i \wedge \hat{U}_j ,
\] (B4)
where \(\alpha_{ij}\) is a symmetric matrix of normalization factors and the wedge product stands for the bivector
\[
\left( \hat{U}_i \wedge \hat{U}_j \right)^{I J} = \hat{U}_i[^I \hat{U}_j[^J] = \hat{U}_i[^I \hat{U}_j[^J - \hat{U}_j[^I \hat{U}_i[^J .
\] (B5)
The closure constraint states that
\[
\sum_{j \neq i} \alpha_{ij} \hat{U}_i \wedge \hat{U}_j = \hat{U}_i \wedge \sum_{j \neq i} \alpha_{ij} \hat{U}_j = 0 \quad \forall \ i = 1, \ldots, 5 .
\] (B6)
Consequently,
\[
\sum_{j=1}^{5} \alpha_{ij} \hat{U}_j = 0 \quad \text{for suitable diagonal elements} \ \alpha_{ii}.
\] (B7)
Next we eliminate one of the five \(\hat{U}_j\) in the last equation, say, \(\hat{U}_m\). For arbitrary \(k, l, k \neq l\),
\[
\sum_j (\alpha_{km} \alpha_{lj} - \alpha_{lm} \alpha_{kj}) \hat{U}_j = \sum_{j \neq m} (\alpha_{km} \alpha_{lj} - \alpha_{lm} \alpha_{kj}) \hat{U}_j = 0 .
\] (B8)
Since the bivectors are non–degenerate, four of the five normal vectors \(\hat{U}_i\) must be linearly independent. Therefore,
\[
\alpha_{km} \alpha_{lj} = \alpha_{kj} \alpha_{lm} .
\] (B9)
In particular, for \(l = j\),
\[
\alpha_{km} \alpha_{jj} = \alpha_{kj} \alpha_{jm} .
\] (B10)
By non–degeneracy, all \(\alpha_{ij}\) are non–zero, so
\[
\alpha_{km} = \frac{\alpha_{kj} \alpha_{jm}}{\alpha_{jj}} = \frac{\alpha_{kj} \alpha_{mj}}{\alpha_{jj}} .
\] (B11)
Let us pick one \(j = j_0\) and define
\[
\alpha_i = \frac{\alpha_{ij_0}}{\sqrt{|\alpha_{j_0 j_0}|}} .
\] (B12)
Then,
\[
\alpha_{ij} = \text{sgn}(\alpha_{j_0 j_0}) \alpha_i \alpha_j
\] (B13)
and the bivectors have the form
\[
X_{ij} = \tilde{\epsilon} \left( \alpha_i \hat{U}_i \right) \wedge \left( \alpha_j \hat{U}_j \right) ,
\] (B14)
where \(\tilde{\epsilon} = \text{sgn}(\alpha_{j_0 j_0})\) is a sign independent of \(i\) and \(j\). From eq. (B7) we also know that
\[
\sum_j \alpha_j \hat{U}_j = 0 .
\] (B15)
By taking the square of eq. (B14), we get
\[
j_{ij}^2 = \alpha_i^2 \alpha_j^2 \sin^2 \theta_{ij} , \quad \cos \theta_{ij} = \hat{U}_i \cdot \hat{U}_j ,
\] (B16)
which fixes the modulus of $\alpha_i$ given $j_{ij}$ and $\hat U_i$. Eq. (B15) implies furthermore that the signs $\text{sgn} \alpha_i$ are fixed up to an overall sign change $\alpha_i \rightarrow -\alpha_i$, $i = 1, \ldots, 5$.

At this point, we can reconstruct the tetrad and co–tetrad vectors. Define

$$U_i \equiv \frac{\alpha_i \hat U_i}{\sqrt{V_4}} \quad \text{with} \quad V_4 \equiv \det \left( \alpha_2 \hat U_2, \ldots, \alpha_5 \hat U_5 \right).$$

Then, we obtain that

$$\frac{1}{V_4} = \det (U_2, \ldots, U_5)$$

and

$$X_{ij} = \tilde{\epsilon} |V_4| U_i \wedge U_j = \epsilon V_4 U_i \wedge U_j,$$

where $\epsilon \equiv \tilde{\epsilon} \text{sgn}(V_4)$. By proposition VI.4 and A.1 the $U_i$’s define corresponding dual vectors $E_{ij}$ such that

$$X_{ij} = \epsilon \sum_{m,n} \frac{1}{2} \epsilon_{kijmn} \ast (E_{mk} \wedge E_{nk}), \quad k \neq i,j.$$

2. Reconstruction of co–tetrad and tetrad

Next we deal with the equations (83) that relate variables from neighbouring 4–simplices. We consider an edge $e = (vv')$ and employ the following shorthand notation:

$$U_0 \equiv U_e(v), \quad U'_0 \equiv g_{vv'} U_e(v'),$$

$$U_i \equiv U_{e_i}(v), \quad U'_i \equiv g_{vv'} U'_e(v),$$

$$E_{ij} \equiv E_{e_ie_j}(v), \quad E'_{ij} \equiv g_{vv'} E_{e_ie_j}(v').$$

The labels $i$ are chosen such that $(e_i e'_i)$ corresponds to one of the four faces adjacent to $e$ (see fig. 5). One can check that this ordering is compatible with our requirement that orientations of neighbouring 4–simplices are consistent.

As seen in section VII, the exterior closure constraints leads to

$$\sum_i U_i = -U_0 \quad \text{and} \quad \sum_i U'_i = -U'_0.$$
Moreover, due to the eqns. (B3), the \( U \) and \( U' \) are related as follows:
\[
\frac{U'}{|U'|} = \tilde{\epsilon} \frac{U_0}{|U_0|}, \quad X_{0i} = \hat{\epsilon} V(U_0 \wedge U_i) = \hat{\epsilon}' V'(U_0' \wedge U_i'), \tag{B25}
\]
where \( \epsilon, \epsilon', \tilde{\epsilon} = \pm 1 \) and
\[
1/V \equiv \det (U_1, U_2, U_3, U_4), \quad 1/V' \equiv \det (U_1', U_2', U_3', U_4'). \tag{B26}
\]

**Proposition B.2** The conditions \((B24), (B25)\) imply that
\[
\epsilon = \epsilon', \quad \tilde{\epsilon} = \text{sgn}(VV'), \quad VU_0 = \alpha V'U_0' \quad \text{and} \quad U_i' = \alpha U_i + a_i U_0, \tag{B27}
\]
where \( \alpha \) is an arbitrary sign factor and \( a_i \) are coefficients such that \( \sum_i a_i = \alpha (1 - \frac{V}{V'}) \). Moreover, for the co–tetrad vectors \( E_{ij} \) and \( E'_{ij} \) one has the identity
\[
E'_{ij} = \alpha E_{ij}. \tag{B28}
\]

**Proof** The equations \((B25)\) tell us that \( U_0' \) is proportional to \( U_0 \) and that \( U_i' \) is a linear combination of \( U_i \) and \( U_0 \). More precisely,
\[
U_i' = \tilde{\epsilon} \epsilon \epsilon' \frac{|U_0|}{|U_0'|} V U_i + a_i U_0, \tag{B29}
\]
where \( a_i \) are coefficients such that \( \sum_i U_i' = -U_0' \). It follows that \( \sum_i a_i - \tilde{\epsilon} \epsilon \epsilon' \frac{|U_0|}{|U_0'|} V = -\frac{|U_0'|}{|U_0|} \).
Using the relation \((B29)\), we obtain
\[
1/V' = \det (U_1', U_2', U_3', U_4') = \det (U_0, U_1', U_2', U_3') \tag{B30}
\]
\[
= \frac{|U_0|}{|U_0'|} \left( \tilde{\epsilon} \epsilon \epsilon' \frac{|U_0|}{|U_0'|} V \right)^3 \det (U_0, U_1, U_2, U_3) = \epsilon' \left( \frac{|U_0|}{|U_0'|} V' \right)^2 1/V'. \tag{B31}
\]
Thus, \( \epsilon = \epsilon' \) and \( |U_0|V = \pm |U_0'|V' \). By defining the sign factor
\[
\alpha \equiv \tilde{\epsilon} \frac{|U_0|}{|U_0'|}, \tag{B32}
\]
we arrive at eq. \((B27)\).

By using eq. \((A8)\) of prop. \((A.1)\), we can now compute explicitly the relation between co–tetrad vectors for edges that are shared by the 4–simplices dual to \( v \) and \( v' \):
\[
E'_{jk} = \frac{1}{3!} V' \epsilon_{jk} i^i i^j i^k (U_i' \wedge U_{i2} \wedge U_{i3}) = \alpha^3 V \epsilon_{jk} i^i i^j i^k (U_i \wedge U_{i2} \wedge U_{i3}) = \alpha E_{jk}. \tag{B33}
\]

The relation \( E'_{ij} = \alpha E_{ij} \) shows that the \( E_{ij} \) satisfy the metricity condition (iii) in the definition of a co–tetrad. Therefore, the co–tetrad and tetrad vectors determine a consistent 4–geometry on the simplicial complex.
