Effective multiplicity one on $GL_n$ and narrow zero-free regions for Rankin-Selberg $L$-functions

FARRELL BRUMLEY

Abstract

We establish zero-free regions tapering as an inverse power of the analytic conductor for Rankin-Selberg $L$-functions on $GL_n \times GL_{n'}$. Such zero-free regions are equivalent to commensurate lower bounds on the edge of the critical strip, and in the case of $L(s, \pi \times \tilde{\pi})$, on the residue at $s = 1$. As an application we show that a cuspidal automorphic representation on $GL_n$ is determined by a finite number of its Dirichlet series coefficients, and that this number grows at most polynomially in the analytic conductor.

Let $\mathbb{A}$ be the ring of adeles over a number field $F$ and let $\pi$ and $\pi'$ be two cuspidal representations of $GL_n(\mathbb{A})$ with restricted tensor product decompositions $\pi = \bigotimes_v \pi_v$ and $\pi' = \bigotimes_v \pi'_v$ over all places $v$ of $F$. The strong multiplicity one theorem asserts that if $\pi_v \simeq \pi'_v$ for all but finitely many places $v$, then $\pi = \pi'$. This was proven by Piatetski-Shapiro [PS] using the uniqueness of the Kirillov model and then by Jacquet and Shalika [J-S] using Rankin-Selberg $L$-functions. Much more can be said however about the extent to which agreement of local factors on a suitable subset of the primes determines global equality. For instance, Moreno has shown [Mo1] that for some finite $Y(\pi, \pi')$ the condition that $\pi_p \simeq \pi'_p$ for spherical non-archimedean $p$ with absolute norm $N_p \leq Y(\pi, \pi')$ is sufficient to imply $\pi = \pi'$. From the analytic perspective, the crucial issue are the zeros of Rankin-Selberg $L$-functions: under GRH for both $L(s, \pi \times \pi')$ and $L(s, \pi \times \tilde{\pi})$, if the analytic conductors of $\pi$ and $\pi'$ are less than $Q$, then $Y(\pi, \pi') = O(\log^2 Q)$ (see, for example, [G-H]).

One wants to give an upper bound on $Y(\pi, \pi')$ which grows moderately in $Q$ without assuming a Riemann Hypothesis. In certain settings, this can be done through non-analytic means. As an example, Murty [Mu] used the Riemann-Roch theorem on the modular curve $X_0(N)$ to show that when $\pi$ and $\pi'$ correspond to holomorphic modular forms of level $N$ and even weight $k$, then $Y(\pi, \pi') = O(k N \log \log N)$. For the case of Maass forms on the upper half plane, Huntley [H] used the method of Rayleigh quotients to show that $Y(\pi, \pi')$ grows at most linearly in the eigenvalue. More recently, Baba, Chakraborty, and Petridis [B-C-P] proved a linear bound in the level and weight of holomorphic Hilbert modular forms, again using Rayleigh quotients.
This paper is concerned with, among other things, the determination of cusp forms on $\text{GL}_n$ by their first few local components when measured with respect to both the archimedean and non-archimedean parameters. This case has been treated elsewhere by Moreno [Mo2], who derived a polynomial bound for $Y(\pi, \pi')$ when $n = 2$ but could do no better than $Y(\pi, \pi') = O(e^{A \log^2 Q})$ for some constant $A > 0$ when $n \geq 3$. Moreno’s idea was to demonstrate a region of non-vanishing for $L(s, \pi \times \pi')$ within the critical strip and apply this to an explicit formula relating sums over zeros to sums over primes. For this strategy to work, quite a wide zero-free region is needed, one which decays logarithmically in all parameters (with the possible exception of one real zero). Unable to obtain this for $n$ greater than 2, Moreno used the phenomenon of zero repulsion to extract his exponential bound. In this paper, we obtain a modest zero-free region for $L(s, \pi \times \pi')$ for all $n \geq 2$, decaying polynomially in all parameters, and deduce from this, through an elementary method which, by contrast with Moreno’s, uses sums over integers rather than primes, that $Y(\pi, \pi') = O(Q^A)$ for some constant $A > 0$.

Throughout this paper $\pi$ and $\pi'$ will denote (unitary) cuspidal automorphic representations of $\text{GL}_n(A)$ ($n \geq 1$). We will make the implicit assumption that the central characters of $\pi$ and $\pi'$ are trivial on the product of positive reals $\mathbb{R}^+$ when embedded diagonally into the (archimedean places of) the ideles. Under this normalization the Rankin-Selberg product $L(s, \pi \times \pi')$ has a pole at $s = 1$ if and only if $\pi' = \tilde{\pi}$.

The starting point of our inquiry is our Theorem 3 where we give a lower bound on the polar part of $L(s, \Pi \times \tilde{\Pi})$ for $\Pi$ an isobaric representation of $\text{GL}_d(A)$. Theorem 3 is proven through an approximation of the polar part by a smooth average of the coefficients of $L(s, \pi \times \pi')$. That these coefficients are non-negative, and that certain of them are bounded away from zero (our Proposition 1), ensures that their average cannot be too small. The error in the approximation is controlled through Mellin inversion by the functional equation of $L(s, \pi \times \pi')$ and is negligible as soon as the length of the sum is a large enough power of $Q$.

We then proceed to derive a first consequence of Theorem 3, proving an inverse polynomial lower bound on the edge of the critical strip for Rankin-Selberg $L$-functions $L(s, \pi \times \pi')$. To simplify the statement, we write $\text{Aut}_n(\leq Q)$ for the set of all cuspidal automorphic representations $\pi$ of $\text{GL}_n(A)$ with analytic conductor $C(\pi)$ less than $Q$.

**Theorem 5.** Let $\pi \in \text{Aut}_n(\leq Q)$ and $\pi' \in \text{Aut}_{n'}(\leq Q)$ and assume that $\pi \neq \tilde{\pi}'$. Let $t \in \mathbb{R}$. There exists $A = A(n, n') > 0$ such that

$$|L(1 + it, \pi \times \pi')| \gg_{n,n'} (Q(1 + |t|))^{-A}.$$

To prove Theorem 5 we apply Theorem 3 to the isobaric sum $\Pi = \pi \otimes |\det|^{it/2} \oplus \pi' \otimes |\det|^{it/2}$ on $\text{GL}_d$, where $d = n + n'$. With this choice of $\Pi$, we force the polar part of $L(s, \Pi \times \tilde{\Pi})$ to contain $L(1 + it, \pi \times \pi')$ as a factor. The convexity principle can be used
to bound the factors that remain from above by a power of $Q$. Since $C(\Pi \times \tilde{\Pi})$ is itself bounded by a power of $Q$, we can then make the passage from the lower bound furnished by Theorem 3 to that for $L(1 + it, \pi \times \pi')$ as stated in Theorem 5.

Theorem 5 has already found applications elsewhere in the literature. For instance, Lapid [L] has recently shown that a lower bound on $L(1 + it, \pi \times \pi')$ that decays at most polynomially in $Q(1 + |t|)$ is a central issue in the convergence of Jacquet’s relative trace formula.

From Theorem 5 it is a short hop to obtain narrow zero-free regions. It is known (see, for instance, [S]) that when both $\pi$ and $\pi'$ are self-dual, the method of de la Vallée Poussin can be carried out successfully to give a (wide) zero-free region for $L(s, \pi \times \pi')$ of logarithmic type when the imaginary parameter $|t| \geq 1$. When exactly one is self-dual, a standard zero-free region can be derived for all $t$. Making the most of recent progress in functoriality, Ramakrishnan and Wang [R-W] have eliminated any assumption of self-duality in certain low rank cases. More precisely, they show that for $\pi$ and $\pi'$ on $GL_2$ over $\mathbb{Q}$, the $L$-functions $L(s, \pi \times \pi')$ and $L(s, \text{sym}^2 \pi \times \text{sym}^2 \pi)$, as long as they are not divisible by $L$-functions of quadratic characters, admit no Siegel zeros. For the cases that remain, we derive as a simple consequence of Theorem 5 a zero-free region for $L(s, \pi \times \pi')$ for arbitrary $\pi$ and $\pi'$, the width of which tapers polynomially in all parameters, and which remains valid even for $t = 0$. This is recorded in Corollary 6.

The methods contained in Sections 2 and 3, which combine to give Theorem 5, can be thought of as an effectuation of Landau’s lemma. By contrast, Sarnak outlines a technique in [S] to show effective non-vanishing of $L$-functions through poles of Eisenstein series, and this too has now been carried out successfully by Gelbart, Lapid, and Sarnak [G-L-S]. These latter authors use the Langlands-Shahidi method to prove an inverse polynomial lower bound of certain $L$-functions along $\text{Re}(s) = 1$, but in the $t$-aspect only (and away from the real line). Relative to the setting of our Theorem 5 their result applies to a (at present) much larger class of $L$-functions. Namely, to any $L$-function or product of $L$-functions obtained as the residue of an Eisenstein series they give a lower bound along $\text{Re}(s) = 1$; without full functoriality, it cannot be said that each one of these is the $L$-function of an automorphic form on $GL_n$. One striking application given by the authors of [G-L-S] is to $L(s, \pi, \text{sym}^9)$, the symmetric-ninth power $L$-function of a cusp form $\pi$ on $GL_2$: they prove a lower bound for $L(s, \pi, \text{sym}^9)$ along $\text{Re}(s) = 1$ despite the fact that it is not yet known whether $L(s, \pi, \text{sym}^9)$ is zero-free to the right of 1.

The final section in this paper is devoted to deriving the following effective multiplicity one statement. In the proof, we exploit the fact that, with the aforementioned normalization on the central character, $L(s, \pi \times \tilde{\pi}')$ has a pole at $s = 1$ if and only if $\pi = \pi'$. The idea is that Theorem 3 quantifies this property by providing a lower bound on the residue of $L(s, \pi \times \tilde{\pi})$.

**Theorem 7.** Let $n \geq 1$. Let $\pi = \otimes_v \pi_v$ and $\pi' = \otimes_v \pi'_v$ be in $\text{Aut}_n(\leq Q)$. Denote by
the set of all finite places of $F$ at which either $\pi$ or $\pi'$ is ramified. There exist constants $c = c(n) > 0$ and $B = B(n) > 0$ such that if $\pi_p \simeq \pi'_p$ for all prime ideals $p \notin S$ with absolute norm $N_p \leq cQ^B$, then $\pi = \pi'$.

The proof of Theorem 7 allows for a weakening of the hypotheses, to the extent that one may suppose a mere approximate equivalence between the Dirichlet coefficients of the two forms and still retain the conclusion. In this way we are able to deduce in Corollary 9 that the set $\text{Aut}_n(\leq Q)$ is finite.

Acknowledgements: This paper came about through the suggestion of my thesis advisor, Peter Sarnak, and I would like to thank him now for his continual encouragement in this project. I am also happy to acknowledge Erez Lapid for making important suggestions to correct the exposition and for explaining his own related work. Lastly, I am indebted to Akshay Venkatesh for pointing out an improvement to an earlier version of Lemma 1.

1 Preliminaries on $L$-functions

In this section we give basic notation and definitions of standard and Rankin-Selberg $L$-functions, including their fundamental analytic properties and functional equations.

Standard $L$-function. Let $\pi$ be a cusp form on $\text{GL}_n$ over a number field $F$. To every prime ideal $p$ at which $\pi_p$ is unramified there is an associated set of $n$ non-zero complex Satake parameters $\{\alpha_{\pi}(\mathfrak{p}, i)\}$ out of which one may define local $L$-functions

$$L(s, \pi_p) = \prod_{i=1}^{n} (1 - \alpha_{\pi}(\mathfrak{p}, i)N_p^{-s})^{-1}.$$  (1)

At $p$ where $\pi_p$ is ramified the local $L$-function is defined in terms of the Langlands parameters of $\pi_p$. It is of the form $L(s, \pi_p) = P_p(N_p^{-s})^{-1}$ where $P_p(x)$ is a polynomial of degree at most $n$ and $P_p(0) = 1$. It is possible to write the local factors at ramified primes in the form of (1) with the convention that some of the $\alpha_{\pi}(p, i)$’s may be zero. The $\alpha_{\pi}$ satisfy the bound

$$|\alpha_{\pi}(p, i)| \leq N_p^{1/2-(n^2+1)^{-1}}$$  (2)

by the work of Luo-Rudnick-Sarnak [L-R-S].

At each archimedean place $v$ a set of $n$ complex Langlands parameters $\{\mu_{\pi}(v, i)\}_{i=1}^{n}$ is associated to $\pi_v$. The local factor at $v$ is defined to be

$$L(s, \pi_v) = \prod_{i=1}^{n} \Gamma_{F_v}(s + \mu_{\pi}(v, i)),$$
where $\Gamma_\mathfrak{r}(s) = \pi^{-s/2}\Gamma(s/2)$ and $\Gamma_C(s) = 2(2\pi)^{-s}\Gamma(s)$. The $\mu_\pi$ satisfy

$$|\text{Re } \mu_\pi(v, i)| \leq 1/2 - (n^2 + 1)^{-1}$$

again by [L-R-S].

We denote by $\tilde{\pi}$ the contragredient representation of $\pi$. It is an irreducible cuspidal representation of $GL_n(\mathbb{A})$. For any place $v$ of $F$, $\tilde{\pi}_v$ is equivalent to the complex conjugate $\overline{\pi}_v$ [G-K], and hence

$$\{\alpha_{\tilde{\pi}}(v, i)\} = \{\bar{\alpha}_\pi(v, i)\} \quad \text{and} \quad \{\mu_{\tilde{\pi}}(v, i)\} = \{\mu_\pi(v, i)\}.$$

By the bounds in (2), the product $\prod_{p<\infty} L(s, \pi_p)$ converges absolutely on $\text{Re}(s) > 3/2 - (n^2 + 1)^{-1}$ (in fact on $\text{Re}(s) > 1$, by Rankin-Selberg theory). We write this product as a Dirichlet series over the integral ideals of the ring of integers $O_F$ of $F$:

$$L(s, \pi) = \prod_{v<\infty} L(s, \pi_v) = \sum_n \lambda_\pi(n) Nn^{-s}.$$ 

Let $S_\infty$ denote the set of the infinite places. The complete $L$-function, defined to be $\Lambda(s, \pi) = L(s, \pi) \prod_{v\in S_\infty} L(s, \pi_v)$, is an entire function (except when $\pi$ is the trivial representation on $GL_1$ so that $L(s, \pi)$ is the zeta function). $\Lambda(s, \pi)$ has order 1 and is bounded in vertical strips. It satisfies a functional equation $\Lambda(s, \pi) = W(\pi) q(\pi)^{1/2-s} \Lambda(1 - s, \tilde{\pi})$ where $q(\pi)$ is the arithmetic conductor and $W(\pi)$, a complex number of modulus 1, is the root number. We define

$$\lambda_\infty(\pi; t) = \prod_{i=1}^n \prod_{v\in S_\infty} (1 + |it + \mu_\pi(v, i)|)$$

and call $C(\pi; t) = q(\pi)\lambda_\infty(\pi; t)$ the analytic conductor of $\pi$ (along the line $s = 1 + it$). This definition was originally given in [I-S]. We denote $C(\pi; 0)$ by $C(\pi)$.

**Rankin-Selberg $L$-functions.** Let $\pi = \bigotimes_v \pi_v$ and $\pi' = \bigotimes_v \pi'_v$ be cuspidal representations of $GL_n(\mathbb{A})$ and $GL_{n'}(\mathbb{A})$. For prime ideals $\mathfrak{p}$ at which neither $\pi_\mathfrak{p}$ nor $\pi'_\mathfrak{p}$ is ramified let $\{\alpha_\pi(\mathfrak{p}, i)\}_{i=1}^n$ and $\{\alpha_{\pi'}(\mathfrak{p}, i)\}_{i=1}^{n'}$ be the respective Satake parameters of $\pi$ and $\pi'$. The Rankin-Selberg $L$-function at such a $\mathfrak{p}$ is defined to be

$$L(s, \pi_\mathfrak{p} \times \pi'_\mathfrak{p}) = \prod_{i=1}^n \prod_{j=1}^{n'} (1 - \alpha_{\pi \times \pi'}(\mathfrak{p}, i, j) N\mathfrak{p}^{-s})^{-1}.$$ 

These parameters satisfy

$$|\alpha_{\pi \times \pi'}(\mathfrak{p}, i, j)| \leq 1 - (n^2 + 1)^{-1} - (n'^2 + 1)^{-1}.$$ (4)
At primes at which either \( \pi_p \) or \( \pi'_p \) is unramified we have

\[
\{ \alpha_{\pi \times \pi'}(p, i, j) \} = \{ \alpha_{\pi}(p, i)\alpha_{\pi'}(p, j) \}.
\]

At each infinite place \( v \) there exists a set of \( nn' \) parameters \( \{ \mu_{\pi \times \pi'}(v, i, j) \mid 1 \leq i \leq n, 1 \leq j \leq n' \} \) such that the local factor at \( v \) is

\[
L(s, \pi_v \times \pi'_v) = \prod_{i=1}^{n} \prod_{j=1}^{n'} \Gamma_{F_v}(s + \mu_{\pi \times \pi'}(v, i, j)).
\]

At any place \( v \) we have

\[
\{ \mu_{\pi \times \pi'}(v, i, j) \} = \{ \mu_{\pi}(v, i) + \mu_{\pi'}(v, j) \}
\]

and

\[
|\text{Re } \mu_{\pi \times \pi'}(v, i, j)| \leq 1 - (n^2 + 1)^{-1} - (n'^2 + 1)^{-1}.
\]

When the infinite place \( v \) is unramified for both \( \pi \) and \( \pi' \) we have

\[
\{ \mu_{\pi \times \pi'}(v, i, j) \} = \{ \mu_{\pi}(v, i) + \mu_{\pi'}(v, j) \}.
\]

By the bounds (4), the product \( \prod_{p<\infty} L(s, \pi_p \times \pi'_p) \) converges absolutely in \( \text{Re}(s) > 2 - (n^2 + 1)^{-1} - (n'^2 + 1)^{-1} \). We write this product as a Dirichlet series over all integral ideals of the ring of integers \( \mathcal{O}_F \) of \( F \):

\[
L(s, \pi \times \pi') = \prod_{\pi<\infty} L(s, \pi_p \times \pi'_p) = \sum_{n} \lambda_{\pi \times \pi'}(n)Nn^{-s}.
\]

It can be shown through Rankin-Selberg integrals [J-PS-S] that the Euler product \( L(s, \pi \times \pi') \) actually converges in \( \text{Re}(s) > 1 \). With \( S_{\infty} \) as usual representing the set of infinite places, the completed \( L \)-function \( \Lambda(s, \pi \times \pi') = L(s, \pi \times \pi') \prod_{v\in S_{\infty}} L(s, \pi_v \times \pi'_v) \) extends to a meromorphic function on \( \mathbb{C} \), is bounded (away from its poles) in vertical strips, and is of order 1. Under our normalization on the central characters, \( \Lambda(s, \pi \times \pi') \) is entire if and only if \( \tilde{\pi} \neq \pi' \). The poles of \( \Lambda(s, \pi \times \pi) \) are simple and are located at \( s = 1 \) and \( s = 0 \).

The functional equation \( \Lambda(s, \pi \times \pi') = W(\pi \times \pi')q(\pi \times \pi')^{1/2-s}\Lambda(1-s, \tilde{\pi} \times \tilde{\pi}') \) is valid for all \( s \), where \( q(\pi \times \pi') \) is the arithmetic conductor and \( W(\pi \times \pi') \), a complex number of modulus 1, is the root number. Let

\[
\lambda_{\infty}(\pi \times \pi'; t) = \prod_{i=1}^{n} \prod_{j=1}^{n'} \prod_{v\in S_{\infty}} (1 + |it + \mu_{\pi \times \pi'}(v, i, j)|).
\]

As in [I-S] we define \( C(\pi \times \pi'; t) = q(\pi \times \pi')\lambda_{\infty}(\pi \times \pi'; t) \) to be the analytic conductor of the \( L \)-function \( L(s, \pi \times \pi') \). We write \( C(\pi \times \pi') := C(\pi \times \pi'; 0) \).
Separation of Components. We have $\lambda_\infty(\pi \times \pi'; t) \leq \lambda_\infty(\pi; 0)^n \lambda_\infty(\pi'; t)^n$. For unramified places this is easy to see by (7). For the ramified infinite places, see the calculations in [R-S, Appendix]. The arithmetic conductor $q(\pi \times \pi')$ separates according to the following result of Bushnell-Henniart [B-H]: $q(\pi \times \pi') \leq q(\pi)n'q(\pi')/(q(\pi), q(\pi'))$. These together produce

$$C(\pi \times \pi'; t) \leq C(\pi') \leq C(\pi') = C(\pi'; t)^n \leq C(\pi/n')C(\pi')/(1 + |t|)^n[n[F,\mathbb{Q}].$$

Preconvex bound. Let $\mu \in \mathbb{C}$ be such that $\text{Re}\mu \geq -1 + \theta$ for some $\theta > 0$. By Stirling’s asymptotic formula for the Gamma function, for $s = \sigma + it$ where $\sigma < \theta$,

$$\frac{\Gamma((1 - s + \pi)/2)}{\Gamma((s + \mu)/2)} \ll (1 + |it + \mu|)^{1/2 - \sigma}.$$ 

Let $\theta = (n^2 + 1)^{-1}$ and $\theta' = (n'^2 + 1)^{-1}$. When combined with the duplication formula $\Gamma_C(s) = \Gamma_R(s)\Gamma_R(s + 1)$ and displays (5) and (6), this gives the following estimate on the quotient for $\sigma < \theta + \theta'$:

$$\frac{L(1 - s, \pi \times \pi')}{L(s, \pi \times \pi')} \ll \lambda_\infty(\pi \times \pi'; t)^{1/2 - \sigma}.$$ 

(9)

From the bounds (4) we deduce $L(s, \pi \times \pi') = O(1)$ on $\text{Re}(s) \geq \sigma_0$ for any $\sigma_0 > 2 - \theta - \theta'$. By the functional equation and the above estimate (9), $L(\sigma + it, \pi \times \pi') = O(C(\pi \times \pi'; t)^{1/2 - \sigma})$ on $\sigma \leq \sigma_0$ for any $\sigma_0 < -1 + \theta + \theta'$. Using the Phragmén-Lindelöf principle and the nice analytic properties of $L(s, \pi \times \pi')$ the following preconvex bound in the interval $-1 + \theta + \theta' \leq \sigma \leq 2 - \theta - \theta'$ is obtained:

$$L(\sigma + it, \pi \times \pi') \ll e \cdot C(\pi \times \pi'; t)^{l(\sigma) + \epsilon},$$ 

(10)

where $l(\sigma)$ is the linear function satisfying $l(-1 + \theta + \theta') = 3/2 - \theta - \theta'$ and $l(2 - \theta - \theta') = 0$. Note that the slope of $l(\sigma)$ is $-1/2$, regardless of $\theta, \theta'$.

Isobaric representations. An isobaric representation $\Pi$ on $\text{GL}_d$ can be written

$$\Pi = \pi_1 \otimes |\det|^{t_1} \oplus \cdots \oplus \pi_\ell \otimes |\det|^{t_\ell},$$

where $\pi_j$ is a cuspidal form on $\text{GL}_{n_j}$ with $\sum n_i = d$, and $t_j \in \mathbb{R}$. The $L$-function $L(s, \Pi)$ decomposes as a product $L(s, \Pi) = \prod_j L(s + it_j, \pi_j)$, and its analytic conductor is $C(\Pi; t) = \prod_j C(\pi_j; t + t_j)$. Let

$$\Pi' = \pi_1' \otimes |\det|^{t_1'} \oplus \cdots \oplus \pi_\ell' \otimes |\det|^{t_\ell'}.$$
be another isobaric representation on \( GL_{d'} \), with \( \pi'_j \) on \( GL_{n'_j} \), \( \sum_i n'_i = d' \), and \( t'_j \in \mathbb{R} \). Then the Rankin-Selberg product is

\[
\mathcal{L}(s, \Pi \times \Pi') = \prod_{j,k} \mathcal{L}(s + t_j + t'_k, \pi_j \times \pi'_k)
\]

with analytic conductor

\[
\mathcal{C}(\Pi \times \Pi'; t) = \ell \prod_{j=1}^{\ell} \mathcal{C}(\pi_j \times \pi'_k; t + t'_k).
\]

As usual we set \( \mathcal{C}(\Pi \times \Pi') = \mathcal{C}(\Pi \times \Pi'; 0) \).

2 A lower bound on the polar part of \( \mathcal{L}(s, \Pi \times \tilde{\Pi}) \)

The goal of this section is to establish Theorem 3 wherein a lower bound is given on the polar part of \( \mathcal{L}(s, \Pi \times \tilde{\Pi}) \) for \( \Pi \) an isobaric representation of \( GL_d(A) \). We preface the proof by two lemmas. Lemma 1 shows that certain of the coefficients found in the Dirichlet series of \( \mathcal{L}(s, \Pi \times \tilde{\Pi}) \) are bounded away from zero. In Lemma 2, this fact combines with the positivity of each one of the coefficients to bound their partial sum from below by a positive power of the length. Theorem 3 will then be shown to follow from these two lemmas through Mellin inversion.

**Lemma 1.** Let \( d \geq 1 \). For non-zero complex numbers \( \alpha_1, \ldots, \alpha_d \) define the coefficients \( b_k \) by

\[
\sum_{k \geq 0} b_k X^k = \prod_{i=1}^d \prod_{j=1}^d (1 - \alpha_i \alpha_j X)^{-1}.
\]

If the \( \alpha \) satisfy \( |\prod_{i=1}^d \alpha_i| = 1 \), then \( b_d \geq 1 \).

**Proof:** A partition \( \lambda = (\lambda_i) \) is a sequence of nonincreasing non-negative integers \( \lambda_1 \geq \lambda_2 \geq \ldots \) with only finitely many non-zero entries. For a partition \( \lambda \), denote by \( \ell(\lambda) \) the number of non-zero \( \lambda_i \), and set \( |\lambda| = \sum \lambda_i \). For \( \lambda \) such that \( \ell(\lambda) \leq d \), let \( s_\lambda(\alpha) \) be the Schur polynomial associated to \( \lambda \), that is,

\[
s_\lambda(\alpha) = \det(\alpha_i^{\lambda_j + d - j})_{ij} / \det(\alpha_i^{d - j})_{ij}.
\]

By the orthogonality of the Schur polynomials (see, for instance, [Ma]),

\[
\prod_{i=1}^d \prod_{j=1}^d (1 - \alpha_i \alpha_j X)^{-1} = \sum_{\ell(\lambda) \leq d} |s_\lambda(\alpha)|^2 X^{|\lambda|}.
\]

For \( \lambda = (\lambda_1, \ldots, \lambda_d, 0, \ldots) \), set \( \lambda = (\lambda_1 - \lambda_d, \ldots, \lambda_{d-1} - \lambda_d, 0, \ldots) \). Then \( s_\lambda(\alpha) = \alpha_1^{\lambda_d} \ldots \alpha_d^{\lambda_d} s_\lambda(\alpha) \), and since \( |\prod_{i=1}^d \alpha_i| = 1 \), this gives \( |s_\lambda(\alpha)|^2 = |s_\lambda(\alpha)|^2 \). Furthermore,
for any pair \((\lambda, k)\), where \(\lambda\) is a partition satisfying \(\ell(\lambda) \leq d - 1\) and \(k \geq 0\) is an integer, there exists a unique partition \(\lambda^{(k)}\) with \(\ell(\lambda^{(k)}) \leq d\) and \(|\lambda^{(k)}| = |\lambda| + kd\) such that \(\hat{\lambda}^{(k)} = \lambda\). This implies

\[
\sum_{\ell(\lambda) \leq d} |s_{\lambda}(\alpha)|^2 X^{|\lambda|} = (1 - X^d)^{-1} \sum_{\ell(\lambda) \leq d-1} |s_{\lambda}(\alpha)|^2 X^{|\lambda|}.
\]

If \(|\lambda| = 0\) then \(s_{\lambda}(\alpha) = 1\). The \(d\)-th coefficient in (12) is therefore

\[
b_d = 1 + \sum_{|\lambda| = d, \ell(\lambda) \leq d-1} |s_{\lambda}(\alpha)|^2.
\]

From this we glean \(b_d \geq 1\), as desired. \(\square\)

Let \(S\) be a finite set of prime ideals for the integer ring \(\mathcal{O}_F\) of the number field \(F\). Write \(S = \prod_{p \in S} p\). Let \(d \geq 1\). For each prime \(p \notin S\), let there be associated \(d\) non-zero complex numbers \(\alpha(p, 1), \ldots, \alpha(p, d)\). Let \(b(n)\) be a sequence of non-negative real numbers indexed by the integral ideals of \(\mathcal{O}_F\). Assume that \(b(1) = 1\) and that for \(p \notin S\)

\[
\sum_{k \geq 0} b(p^k)X^k = \prod_{i=1}^{d} \prod_{j=1}^{d} (1 - \alpha(p, i)\overline{\alpha(p, j)}X)^{-1}.
\]

Let \(\psi(x) \in C_c^\infty(0, \infty)\) be a non-negative function such that \(\psi(x) \geq 1\) on \([1, 2]\) and \(\psi(0) = 0\). Let

\[
F(Y) = \sum_n b(n)\psi(Nn/Y),
\]

the sum being over all integral ideals \(n\). Since the coefficients \(b(n)\) and \(\psi\) itself are non-negative, it follows that \(0 \leq F(Y)\). Had we chosen a smoothing function supported in an interval around 0, the identity \(b(1) = 1\) would further imply that \(1 \ll F(Y)\). The following lemma enables us to to take \(\psi(0) = 0\), while still improving upon \(1 \ll F(Y)\) to show actual growth in the parameter \(Y\) as soon as \(Y\) is large enough.

**Lemma 2.** With the notation as above, there exists a constant \(C = C(d) > 0\) such that \(F(Y) \gg Y^{1/d}(\log Y)^{-1}\) for all \(Y \gg_d (\log NS)^C\).

**Proof:** As the coefficients \(b(n)\) and \(\psi\) are non-negative, the sum \(F(Y)\) can be truncated to give

\[
F(Y) \geq \sum_{Y \leq Nn \leq 2Y} b(n)\psi(Nn/Y) \geq \sum_{Y \leq Np \leq 2Y} b(n) \geq \sum_{Y \leq Np^d \leq 2Y} b(p^d).
\]
By (13), the inequality $b(p^d) \geq 1$ of Lemma 1 may be applied to each $p \notin S$. Thus

$$F(Y) \geq \#\{p : Y^{1/d} \leq N_p \leq (2Y)^{1/d}, \ p \notin S\}$$

$$\geq \#\{p : Y^{1/d} \leq N_p \leq (2Y)^{1/d}\} - \#\{p : p \in S\} := A - B.$$  

As long as $A \geq 2B$ we have $F(Y) \geq \frac{1}{2}A$. Since $B \leq \log NS$ and by the Prime Number Theorem $A \sim (Y^{1/d}/\log Y)$ (the implied constant depending also on the number field $F$), the lemma immediately follows. \hfill \Box

Let $\ell$ be a positive integer and $\pi_i$, for $1 \leq i \leq \ell$, be cuspidal automorphic representations of $GL_{n_i}(\mathbb{A})$, $n_i \geq 1$. For real numbers $t_1, \ldots, t_\ell$ such that $t_i = t_j$ if $\pi_i = \pi_j$, let

$$\Pi = \pi_1 \otimes |\det|^{it_1} \boxplus \cdots \boxplus \pi_\ell \otimes |\det|^{it_\ell}$$

be an isobaric representation on $GL_d$, where $d = n_1 + \cdots + n_\ell$. The Rankin-Selberg $L$-function $L(s, \Pi \times \widetilde{\Pi})$ has a pole of order at most $\ell^2$ at $s = 1$ and, under our normalization on the central characters and the assumption on the twists $t_i$, is holomorphic elsewhere along $\Re(s) = 1$. Write the Laurent series expansion of $L(s, \Pi \times \widetilde{\Pi})$ at $s = 1$ as

$$L(s, \Pi \times \widetilde{\Pi}) = \sum_{k=-\ell^2}^{\infty} r_k (s - 1)^k.$$  

The following theorem gives a lower bound on the polar part of $L(s, \Pi \times \widetilde{\Pi})$ of polynomial decay in all parameters. A result of this type was first proved by Carletti, Monte Bragadin and Perelli ([C-MB-P], Theorem 5). Their approach, expressed in the language of Selberg class $L$-functions, uses both the positivity of the coefficients $b(n)$ and the identity $b(1) = 1$. These two data are therefore enough to buy a polynomial dependence on the conductor. By incorporating the extra information contained in our Lemma 1, however, we improve the power of the conductor given by their technique. Indeed without Lemma 1 the lower bound in Theorem 5 would be $C(\Pi \times \Pi)^{-\frac{1}{2}+\epsilon}$. It should be noted that Theorem 5 in fact interpolates the bound $q^{-1/2-\epsilon} \ll \epsilon L(1, \chi)$ for real primitive Dirichlet characters, making it a close approximation of Dirichlet’s bound. We discuss this in more detail in Example 4 following the proof.

**Theorem 3.** With the notation as above, for every $\epsilon > 0$

$$\sum_{k=1}^{\ell^2} |r_{-k}| \gg C(\Pi \times \Pi)^{-\frac{1}{2}(1/d)-\epsilon}.$$  

10
Proof: Let $\psi(x)$ be a smooth compactly supported non-negative function on the positive reals with $\psi(x) \geq 1$ on $[1, 2]$ and $\psi(0) = 0$. The Mellin transform of $\psi$,

$$\hat{\psi}(s) = \int_0^\infty \psi(x)x^{s-1}dx$$

is an entire function with rapid decay in vertical strips. As a Dirichlet series $L(s, \Pi \times \tilde{\Pi})$ can be written $L(s, \Pi \times \tilde{\Pi}) = \sum_n b(n)N_n^{-s}$. Let $F(Y) = \sum_n b(n)\psi(N_n/Y)$. From the Mellin inversion formula it follows that

$$F(Y) = \sum_n b(n) \left( \frac{1}{2\pi i} \int_{\sigma=2}^{\sigma=1} \hat{\psi}(s)(Y/N)^s \, ds \right).$$

The absolute convergence of $L(s, \Pi \times \tilde{\Pi})$ beyond $\sigma = 1$ allows us to switch the order of the sum and integral to obtain

$$F(Y) = \frac{1}{2\pi i} \int_{\sigma=-b}^{\sigma=2} L(s, \Pi \times \tilde{\Pi})\hat{\psi}(s)Y^s \, ds. \quad (14)$$

The integrand in (14) is bounded in vertical strips. The principle of Phragmén-Lindelöf thus allows the contour of integration to be shifted to the left, while picking up the residue of the integrand at $s = 1$. Shifting to the line $\sigma = -b$ for $b \geq 1$ we get

$$F(Y) = \text{Res}_{s=1} \hat{\psi}(s)L(s, \Pi \times \tilde{\Pi})Y^s + \frac{1}{2\pi i} \int_{\sigma=-b} L(s, \Pi \times \tilde{\Pi})\hat{\psi}(s)Y^s \, ds.$$

To estimate the integral, we use (10), (11) and (8), noting the rapid decay in vertical strips of the integrand, to obtain

$$F(Y) = \text{Res}_{s=1} \hat{\psi}(s)L(s, \Pi \times \tilde{\Pi})Y^s + O_\epsilon(C(\Pi \times \Pi)^{l(-b)+\epsilon}Y^{-b}). \quad (15)$$

When $S$ is the set of primes at which $\Pi$ is ramified, the sum $F(Y)$ satisfies the conditions of Lemma 2, so that for $Y \gg_d (\log C(\Pi \times \Pi))^C$

$$Y^{1/d}(\log Y)^{-1} \ll_{d, \epsilon} F(Y). \quad (16)$$

If we take $Y = cC(\Pi \times \Pi)^{l(-b)+1}/b$ for a large enough constant $c > 0$ then (16) is valid and the lower bound on $F(Y)$ in (16) dominates the error term in (15). Given any $\epsilon > 0$ we may take $b$ large enough with respect to $d$, $\epsilon$, and the constant term in $l(b)$ to ensure that $Y = C(\Pi \times \Pi)^{l/2+\epsilon}$ is a stronger condition than that above (recall that the slope of $l(b)$ is $-1/2$). With this value of $Y$ we obtain

$$Y^{1/d}(\log Y)^{-1} \ll_{d, \epsilon} \text{Res}_{s=1} \hat{\psi}(s)L(s, \Pi \times \tilde{\Pi})Y^s. \quad (17)$$
Since $Y^s = Y \sum_{j \geq 0} (\log Y)^j (s - 1)^j / j!$, the right hand side of (17) is
\[
\ll Y \sum_{j+k=-1} |r_k| (\log Y)^j / j! \ll Y (\log Y)^{j^2-1} \sum_{k=1}^{j^2} |r_{-k}|.
\]
(18)
The theorem follows upon substituting $Y = C(\Pi \times \Pi)^{1/2+\epsilon}$ into (17) and (18).

**Example 4.** Let $\pi_1 = \chi$, a primitive real Dirichlet character of modulus $q$, and $\pi_2 = 1$, the trivial character. Then for $\Pi = \pi_1 \boxplus \pi_2 = \chi \boxplus 1$, we have

$L(s, \Pi \times \tilde{\Pi}) = [\zeta(s)L(s, \chi)]^2$, $C(\Pi \times \Pi) \approx q^2$ and $d = 2$. The function $L(s, \Pi \times \tilde{\Pi})$ has a double pole at $s = 1$ and nowhere else, and if we denote by $\gamma = \zeta'(1)$ Euler’s constant, then

$r_{-2} = L(1, \chi)^2$ \quad and \quad $r_{-1} = 2L'(1, \chi)L(1, \chi) + 2\gamma L(1, \chi)^2$.

Applying Theorem 3 gives

\[
\frac{1}{q^{1/2+\epsilon}} \ll \epsilon L(1, \chi) \left( L(1, \chi)(1 + 2\gamma) + 2|L'(1, \chi)| \right).
\]

Since $L^{(k)}(1, \chi) \ll \epsilon (\log q)^k$, we conclude by this technique that

\[
\frac{1}{q^{1/2+\epsilon}} \ll \epsilon L(1, \chi),
\]

which is only slightly worse than what Dirichlet deduced by his class number formula, namely $q^{-1/2} \ll L(1, \chi)$.

### 3 Lower bounds for $L(1 + it, \pi \times \pi')$

We shall now use Theorem 3 to bound from below the value along $\text{Re}(s) = 1$ of the Rankin-Selberg $L$-function $L(s, \pi \times \pi')$. To do so at the point $s = 1 + it$, we construct an auxiliary Dirichlet series $L(s, \Pi \times \tilde{\Pi})$ whose polar part contains $L(1 + it, \pi \times \pi')$ as a factor. Roughly speaking, this coincidence is ensured as soon as the order of the pole at $s = 1$ is equal to the power to which $L(s, \pi \times \pi')$ divides $L(s, \Pi \times \tilde{\Pi})$. This is precisely the case in which one classically appeals to Landau’s lemma to show mere non-vanishing on the line $\text{Re}(s) = 1$. The following theorem, Theorem 5, can therefore be interpreted as an effectuation of Landau’s lemma.

Now that in Example 3 we have measured the quality of the exponent given by Theorem 3, we shall no longer give specific powers of the conductor in our results. One reason
for doing so is that the statements that follow all employ the preconvex bound \( |10| \) which can be improved by progress toward the Ramanujan conjecture (see [Molt]). Beyond that subconvex bounds would improve the exponents even further. There is therefore no compelling reason to specify each exponent, and we greatly simplify the exposition by not doing so.

**Definition.** For a real parameter \( Q \geq 2 \) we denote by \( \text{Aut}_n(\leq Q) \) the set of all cuspidal representations \( \pi \) of \( \text{GL}_n(\mathbb{A}) \) with analytic conductor \( C(\pi) \) less than \( Q \).

**Theorem 5.** Let \( \pi \in \text{Aut}_n(\leq Q) \) and \( \pi' \in \text{Aut}_{n'}(\leq Q) \), and assume \( \pi' \neq \tilde{\pi} \). Let \( t \in \mathbb{R} \). There exists \( A = A(n, n') > 0 \) such that

\[
|L(1 + it, \pi \times \pi')| \gg_{n, n'} (Q(1 + |t|))^{-A}.
\]

**Proof:** Consider the unitary isobaric sum \( \Pi = \pi \otimes |\det|^{it/2} \pi' \otimes |\det|^{it/2} \), defined on \( \text{GL}_d \) where \( d = n + n' \). The Rankin-Selberg product \( L(s, \Pi \times \tilde{\Pi}) \) can be written

\[
L(s, \pi \times \tilde{\pi})L(s, \pi' \times \tilde{\pi}')L(s + it, \pi \times \tilde{\pi}')L(s - it, \tilde{\pi} \times \pi').
\]

We apply Theorem 3 with \( d = n + n' \) to get

\[
|r_1 - 1| + |r_2 - 1| \gg C(\Pi \times \Pi)^{-1/2} (1 - 1/d)^{-\epsilon} - \epsilon. \tag{19}
\]

By the factorization (11) and the separation of components in (8), the analytic conductor \( C(\Pi \times \Pi) \) of \( L(s, \Pi \times \Pi) \) is

\[
C(\pi \times \pi)C(\pi' \times \pi')C(\pi \times \pi'; t)^2 \leq (1 + |t|)^{2mn'\left[F:Q\right]}Q^{4(n + n')}.
\]

Thus the lower bound in (19) becomes

\[
|r_1 - 1| + |r_2 - 1| \gg (Q(1 + |t|))^{-A_1} \tag{20}
\]

for some explicitly given \( A_1 = A_1(n, n') > 0 \).

Using \( L(s, \pi \times \tilde{\pi}') = L(\overline{\pi}, \tilde{\pi} \times \pi') \) we compute \( r_2 = R_1R_1|R(1 + it, \pi \times \tilde{\pi}')|^2 \) and

\[
r_1 = (R_1R_0' + R_0R_1')|L(1 + it, \pi \times \tilde{\pi}')|^2 + 2R_1R_1'\text{Re}(L'(1 + it, \pi \times \tilde{\pi}')L(1 + it, \pi \times \tilde{\pi}')).
\]

The inequality \( \text{Re}(z_1z_2) \leq |z_1z_2| \) and the preconvex bounds

\[
R_1, R_0 \ll Q^{A_2}, \quad L^{(k)}(1 + it, \pi \times \tilde{\pi}') \ll (Q(1 + |t|))^{A_2},
\]

13
for \( k = 0, 1 \), and some \( A_2 = A_2(n, n') > 0 \), now give

\[
\frac{r_1 - r_2}{r_1} \ll |L(1 + it, \pi \times \tilde{\pi}')|(Q(1 + |t|))^{3A_2}.
\]

When combined with (20) this implies the theorem, the power being \( A = A_1 + 3A_2 \).

As was mentioned in the introduction, the method of de la Vallée Poussin can be used under certain circumstances to derive zero-free regions for \( L(s, \pi \times \pi') \) of logarithmic type. For instance, to eliminate the possibility of a real exceptional zero for \( L(s, \pi \times \pi') \), exactly one of \( \pi \) and \( \pi' \) must be self-dual. In certain cases of low rank, Ramakrishnan and Wang [R-W] have eliminated the hypothesis of self-duality. They show that for \( \pi \) and \( \pi' \) on \( GL_2 \) over \( \mathbb{Q} \), the \( L \)-functions \( L(s, \pi \times \pi') \) and \( L(s, \text{sym}^2 \pi \times \text{sym}^2 \pi) \), as long as they are not divisible by \( L \)-functions of quadratic characters, admit no Siegel zeros. In all the cases that remain, the following corollary to Theorem 5 provides a healthy compromise.

**Corollary 6.** Let \( \pi \in \text{Aut}_n(\le Q) \), \( \text{Aut}_{n'}(\le Q) \), and \( t \in \mathbb{R} \). There exist constants \( c = c(n, n') > 0 \) and \( A' = A'(n, n') > 0 \) such that \( L(\sigma + it, \pi \times \pi') \) has no zeros in the interval

\[
1 - \frac{c}{(Q(1 + |t|))^{A'}} \le \sigma \le 1.
\]

**Proof:** Let \( \beta + it \) denote the first zero of \( L(s, \pi \times \pi') \) to the left of 1 along the segment \( \sigma + it \), \( 1/2 < \sigma < 1 \). Then we have

\[
L(1 + it, \pi \times \pi') = \int_{\beta}^{1} L'(\sigma + it, \pi \times \pi') \, d\sigma = (1 - \beta)L'(\sigma_0 + it, \pi \times \pi'),
\]

for some \( \beta \leq \sigma_0 \leq 1 \), by the mean value theorem. We apply the preconvex bound for \( L'(s, \pi \times \pi') \) on the critical line \( \sigma = 1/2 \)

\[
|L'(\sigma_0 + it, \pi \times \pi')| \leq |L'(1/2 + it, \pi \times \pi')| \ll (Q(1 + |t|))^{A_3},
\]

for some \( A_3 = A_3(n, n') > 0 \). We finally apply the lower bound for \( L(1 + it, \pi \times \pi') \) from Theorem 5 to obtain the corollary, the power being \( A' = A + A_3 \).

### 4 Effective multiplicity one

We note that by Theorem 3 when \( \pi \in \text{Aut}_n(\le Q) \), we have

\[
R := \text{Res}_{s=1} L(s, \pi \times \tilde{\pi}) \gg Q^{-B_1}
\]

for a constant \( B_1 = B_1(n) > 0 \).
THEOREM 7. For a real parameter $Q \geq 1$ let $\pi, \pi'$ be in $\text{Aut}_n(\leq Q)$ and $S$ be any finite set of finite places of $F$ satisfying $|S| \ll \log Q$. There exists a constant $B = B(n, S) > 0$ such that if $\pi_\mathfrak{p} \simeq \pi'_\mathfrak{p}$ for all primes ideals $\mathfrak{p} \notin S$ with $N\mathfrak{p} \leq Q^B$, then $\pi = \pi'$.

Proof: Fix as a test function any non-negative $\psi(x) \in C_c^\infty(0, \infty)$ with $\hat{\psi}(1) = 1$. Put $S = \prod_{\mathfrak{p} \in S} \psi$ and define

$$F(Y; \pi \times \pi') = \sum_{(\alpha, \beta) = 1} \lambda_{\pi \times \pi'}(n)\psi(Nn/Y).$$

The hypothesis on the local representations means that the Satake parameters $\{\alpha_{\pi}(\mathfrak{p}, i)\}$ and $\{\alpha_{\pi'}(\mathfrak{p}, i)\}$ agree (as sets) for all prime ideals $\mathfrak{p} \notin S$ with absolute norms within the specified range. It follows that $\lambda_{\pi \times \pi'}(\mathfrak{p}^k) = \lambda_{\pi \times \pi'}(\mathfrak{p}^k)$ for all primes ideals $\mathfrak{p} \notin S$ with $N\mathfrak{p} \leq Q^B$ and all $k \geq 1$. By multiplicativity on coprime ideals, one derives the condition that $\lambda_{\pi \times \pi'}(n) = \lambda_{\pi \times \pi'}(n)$ for all ideals $Nn \leq Q^B$ with $(n, S) = 1$ — that is

$$F(Y; \pi \times \pi') = F(Y; \pi \times \pi') \quad \text{for} \quad Y \leq Q^B. \quad (22)$$

This will henceforth be our assumption.

With $S$ as in the statement of the theorem, let $L_S(s, \pi \times \pi') = \prod_{\mathfrak{p} \notin S} L(s, \pi_\mathfrak{p} \times \pi'_\mathfrak{p})$ and $L^S(s, \pi \times \pi') = \prod_{\mathfrak{p} \in S} L(s, \pi_\mathfrak{p} \times \pi'_\mathfrak{p})$. Mellin inversion gives

$$F(Y; \pi \times \pi') = \frac{1}{2\pi i} \int_{\sigma = 2} L_S(s, \pi \times \pi')\hat{\psi}(s)Y^s \, ds.$$

Let $\theta = \theta(n) = (n^2 + 1)^{-1}$, the quantity appearing in the Luo-Rudnick-Sarnak bounds. We note that the local factor $L(s, \pi \times \pi')$, and thus the product $L^S(s, \pi \times \pi')$, is well-defined and invertible on $\text{Re}(s) > 1 - 2\theta$. Since $L_S(s, \pi \times \pi') = L(s, \pi \times \pi')L^S(s, \pi \times \pi')^{-1}$, the first factor extending meromorphically to $\mathbb{C}$, we may move the contour to the line $\text{Re}(s) = 1 - \theta$, while picking up the residue of the integrand at $s = 1$. This gives

$$F(Y; \pi \times \pi') = \delta_{\pi, \pi'}YRL^S(1, \pi \times \pi')^{-1} + \frac{1}{2\pi i} \int_{\sigma = 1-\theta} L(s, \pi \times \pi')L^S(s, \pi \times \pi')^{-1}\hat{\psi}(s)Y^s \, ds.$$

We bound the individual factors in the above integrand. The preconvex bound on $L(s, \pi \times \pi')$ at $\text{Re}(s) = 1 - \theta$ is $L(1 - \theta + it, \pi \times \pi') \ll (Q(1 + |t|))^{B_2}$ for some $B_2 = B_2(n, \theta) > 0$. By $\{2\}$ we have for $\text{Re}(s) = 1 - \theta$

$$\prod_{1 \leq i, j \leq n} |1 - \alpha_{\pi}(\mathfrak{p}, i)\alpha_{\pi'}(\mathfrak{p}, j)p^{-s}| \leq (1 + p^{-\theta})n^2 = O_n(1).$$

15
Since $|S| \ll \log Q$, this gives $|L^S(s, \pi \times \tilde{\pi}')|^{-1} = O(1)^{|S|} \leq Q^{B_3}$ for some constant $B_3 = B_3(n, \theta) > 0$. By the rapid decay of $\psi(s)$ along vertical lines then

$$F(Y; \pi \times \tilde{\pi}') = \delta_{\pi, \pi'} YRL^S(1, \pi \times \tilde{\pi})^{-1} + O(Y^{1-\theta}Q^{B_2+B_3}).$$

(23)

Let $B > 0$ be a constant such that (22) holds and suppose that $\pi \neq \pi'$. We seek a contradiction to the latter supposition. The key observation is that under both (22) and $\pi \neq \pi'$ the error term of $F(Y; \pi \times \tilde{\pi})$ in equation (23) must dominate the main term. In this range, therefore,

$$Y^\theta = O(R^{-1}L^S(1, \pi \times \tilde{\pi})Q^{B_2+B_3}).$$

(24)

Since $L(s, \pi \times \tilde{\pi})$ has positive coefficients as a Dirichlet series to the right of 1, we can bound $L^S(1, \pi \times \tilde{\pi})$ by the preconvex bound at $s = 1$ of the regularization of $L(s, \pi \times \tilde{\pi})$, so that $L^S(1, \pi \times \tilde{\pi}) = O(Q^{B_4})$. By $R^{-1} \ll Q^{B_1}$ of display (21), equation (24) becomes

$$Y = O(Q^{\theta-1(B_1+B_2+B_3+B_4)}).$$

To force a contradiction, we have only to take $B$ to be $B > \theta^{-1}(B_1 + B_2 + B_3 + B_4)$.

Remark 8. As we have seen, the condition of Theorem 7 that the first few local components be isomorphic can be expressed instead as an equality of the initial coefficients of the Rankin-Selberg $L$-series. In fact this latter condition can be relaxed to an approximate equivalence, in which the difference between the first few coefficients is bounded below by some expression in the conductor.

Having chosen $\pi, \pi' \in Aut_n(\leq Q)$, let the set $S$ consist of precisely those prime ideals at which either $\pi$ or $\pi'$ is ramified. Then $|S| \ll \log Q$ as required in the statement of Theorem 7. Put $S = \prod_{\mathfrak{p} \in S} \mathfrak{p}$. We claim that if $\pi \neq \pi'$ then there exist numbers $B, C > 0$ such that $|\lambda_{\pi}(n_0) - \lambda_{\pi'}(n_0)| \gg Q^{-C}$ for some square-free ideal $(n_0, S) = 1$ with $Nn_0 \leq Q^B$. This relaxation is essential for comparing automorphic forms whose coefficients are not algebraic, as is believed to be the case for Maass wave forms.

By the previous arguments, since $\pi \neq \pi'$,

$$\sum_{(n, S) = 1} (\lambda_{\pi \times \tilde{\pi}}(n) - \lambda_{\pi \times \tilde{\pi}'}(n))\psi(Nn/Y) = YRL^S(1, \pi \times \tilde{\pi})^{-1} + O(Y^{1-\theta}Q^{B_2+B_3}).$$

Under Theorem 7 if $Y = Q^B$ for $B$ large enough then it is the main term that dominates the error term, giving

$$\frac{1}{Y} \sum_{(n, S) = 1} |\lambda_{\pi \times \tilde{\pi}}(n) - \lambda_{\pi \times \tilde{\pi}'}(n)|\psi(Nn/Y) \gg RL^S(1, \pi \times \tilde{\pi})^{-1} \gg Q^{-B_1-B_4}.$$
(simply redo the proof of Theorem 7 using the square-free unramified $L$-function). Recall that $\lambda_{n} = \lambda_{n}(n)\lambda_{n}(n)$ on square-free unramified ideals $n$. By the bounds (2) with $\theta = (n^2 + 1)^{-1}$

$$|\lambda_{n}(n) - \lambda_{n}(n)| \ll Q(1/2-\theta)B|\lambda_{n}(n) - \lambda_{n}(n)|$$

and the claim follows with $C = B_1 + B_4 + (1/2-\theta)B$.

**Corollary 9.** The set $\text{Aut}_n(\leq Q)$ is finite.

**Proof:** Put $S = \{\mathfrak{p} : N\mathfrak{p} \leq Q\}$ and observe that the prime ideals at which any $\pi \in \text{Aut}_n(\leq Q)$ is ramified are contained in $S$. Let $S = \bigsqcup_{i} S_i$ be a disjoint covering of $S$ by subsets $S_i$ satisfying $\prod_{\mathfrak{p} \in S_i} N\mathfrak{p} \leq Q$. Denote by $\text{Aut}_n(S_i)$ the set of all automorphic forms on $\text{GL}_n/F$ unramified at finite places outside of $S_i$. We have $\text{Aut}_n(\leq Q) \subseteq \text{Aut}_n(S_i)$.

We shall show that each intersection $\text{Aut}_n(S_i) \cap \text{Aut}_n(\leq Q)$ is finite.

Let $B > 0$ be a constant (to be fixed later). Put $S_i = \prod_{\mathfrak{p} \in S_i} \mathfrak{p}$. For each $i$ let $I_i$ the set of square-free ideals $(n, S_i) = 1$ with $N_n \leq Q^B$. For constants $\epsilon, c > 0$, consider the space of sequences of complex numbers

$$X_i = X_i(\epsilon, c) = \{(\lambda(n))_{n \in I_i} : |\lambda(n)| \leq cN_n^{1/2-(n^2+1)^{-1}}+\epsilon\}$$

endowed with the natural topology and metric as a closed subset of $\mathbb{C}^{M_i}$, where $M_i = |I_i|$. By the bounds (2), for any $\epsilon > 0$ there exists a constant $c = c(\epsilon) > 0$ such that the set $\text{Aut}_n(S_i)$ maps to $X_i$ via the Fourier coefficient map $FC_i : \pi \mapsto (\lambda_{n}(n))_{n \in I_i}$. Since $|S_i| \leq \log Q$ we may take $B$ as in Theorem 7 to conclude that the restriction of $FC_i$ to $\text{Aut}_n(S_i) \cap \text{Aut}_n(\leq Q)$ is injective. Moreover, the distance squared between any two $\pi$, $\pi' \in \text{Aut}_n(S_i) \cap \text{Aut}_n(\leq Q)$, considered as points in $X_i$, is

$$\text{dist}(\pi, \pi')^2 = |FC(\pi) - FC(\pi')|^2 = \sum_{n \in I_i} |\lambda_{n}(n) - \lambda_{n}(n)|^2.$$  

For $\pi$ and $\pi'$ distinct we thus have

$$\text{dist}(\pi, \pi') \geq \max_{n \in I_i} |\lambda_{n}(n) - \lambda_{n}(n)| \gg Q^{-C}$$ (25)

by Remark 8. Hence $\text{Aut}_n(S_i) \cap \text{Aut}_n(\leq Q)$ is discrete in $X_i$. As $X_i$ is compact, the result follows.

**Remark 10.** The bound on $|\text{Aut}_n(\leq Q)|$ given by the above corollary is probably very poor, possibly exponential. Even though only $O(Q/\log Q)$ sets $S_i$ are needed to cover $S$, it is not evident that the lower bound (25) should be sufficient to prove that the slice $|\text{Aut}_n(S_i) \cap \text{Aut}_n(\leq Q)|$ itself is polynomial in $Q$. A more sophisticated analysis using the trace formula should however give a sharp polynomial bound in all parameters.
