A SHAPE THEOREM FOR THE SPREAD OF AN INFECTION

HARRY KESTEN AND VLADAS SIDORAVICIUS

Abstract. In [KSB] we studied the following model for the spread of a rumor or infection: There is a “gas” of so-called A-particles, each of which performs a continuous time simple random walk on $\mathbb{Z}^d$, with jump rate $D_A$. We assume that “just before the start” the number of A-particles at $x$, $N_A(x,0^{-})$, has a mean $\mu_A$ Poisson distribution and that the $N_A(x,0^{-})$, $x \in \mathbb{Z}^d$, are independent. In addition, there are B-particles which perform continuous time simple random walks with jump rate $D_B$. We start with a finite number of B-particles in the system at time 0. The positions of these initial B-particles are arbitrary, but they are non-random. The B-particles move independently of each other. The only interaction is that when a B-particle and an A-particle coincide, the latter instantaneously turns into a B-particle. [KSB] gave some basic estimates for the growth of the set $\tilde{B}(t) := \{x \in \mathbb{Z}^d : \text{a B-particle visits } x \text{ during } [0,t]\}$. In this article we show that if $D_A = D_B$, then $B(t) = \tilde{B}(t) + [-\frac{1}{2}, \frac{1}{2}]^d$ grows linearly in time with an asymptotic shape, i.e., there exists a non-random set $B_0$ such that $(1/t)B(t) \to B_0$, in a sense which will be made precise.

1. Introduction.

We study the model described in the abstract. One interpretation of this model is that the B-particles represent individuals who are infected, and the A-particles represent susceptible individuals; see [KSB] for another interpretation. $\tilde{B}(t)$ represents the collection of sites which have been visited by a B-particle during $[0,t]$, and $B(t)$ is a slightly fattened up version of $\tilde{B}(t)$, obtained by adding a unit cube around each point of $\tilde{B}(t)$. This fattened up version is introduced merely to simplify the statement of our main result. It is simpler to speak of the shape of the set $(1/t)B(t)$ as a subset of $\mathbb{R}^d$, than of the discrete set $(1/t)\tilde{B}(t)$.

The aim of this paper is to describe how the infection spreads throughout space as time goes on. In [KSB] we proved a first result in this direction in the case $D_A = D_B$. We proved that under this condition there exist constants $0 < C_2 \leq C_1 < \infty$ such that almost surely

$$C(C_2t) \subset B(t) \subset C(2C_1t) \text{ for all large } t,$$

where
\[ C(r) := [-r, r]^d. \]  \hspace{1cm} (1.2)

(1.1) gives upper and lower bounds which are linear in time, for \( B(t) \), the region which has been visited by the infection during [0, t]. However, the upper and lower bounds in (1.1) are not the same. The principal result of this paper is a so-called shape theorem which gives the first order asymptotic behavior of the region \( B(t) \). It shows that \( (1/t)B(t) \) converges to a fixed set \( B_0 \). Thus, not only is the growth linear in time, but \( B(t) \) looks asymptotically like (a scaled version of) \( B_0 \). This of course sharpens (1.1) by ‘bringing the upper and lower bound together’. However, the result (1.1) is a crucial tool for proving the shape theorem. We do not know of a shortcut which proves the shape theorem without much of the development of [KSb] for (1.1). The precise form of the shape theorem here is as follows:

**Theorem 1.** Consider the model described in the abstract. If \( D_A = D_B \), then there exists a non-random, compact, convex set \( B_0 \) such that for all \( \varepsilon > 0 \) almost surely
\[ (1 - \varepsilon)B_0 \subset \frac{1}{t}B(t) \subset (1 + \varepsilon)B_0 \]  \hspace{1cm} (1.3)

The origin is an interior point of \( B_0 \), and \( B_0 \) is invariant under reflections in coordinate hyperplanes and under permutations of the coordinates.

**Remark 1.** It follows immediately from Theorem 1 and Proposition B below that the particle distribution at a large time \( t \) looks as follows: The numbers of particles, irrespective of type, that is \( N_A(x, t) + N_B(x, t), x \in \mathbb{Z}^d \), is a collection of i.i.d. mean \( \mu_A \) Poisson variables plus a finite number of particles which started at time zero at fixed locations (these are the particles added as \( B \)-particles at the start). For every \( \varepsilon > 0 \) there are almost surely no \( A \) particles in \((1 - \varepsilon)tB_0\) and no \( B \)-particles outside \((1 + \varepsilon)tB_0\) for all large \( t \).

Shape theorems have a fairly long history and have become the first goal of many investigations of stochastic growth models. To the best of our knowledge Eden (see [E]) was the first one to ask for a shape theorem for his celebrated ‘Eden model’. The problem turned out to be a stubborn one. The first real progress was due to Richardson, who proved in [Ri] a shape theorem not only for the Eden model, but also for a more general class of models, now called Richardson models. In these models one typically thinks of the sites of \( \mathbb{Z}^d \) as cells which can be of two types (for instance \( B \) and \( A \) or infected and susceptible). Cells can change their type to the type of one of their neighbors according to appropriate rules. One starts with all cells off the origin type \( A \) and cell of type \( B \) at the origin and tries to prove a shape theorem for the set of cells of type \( B \) at a large time. An important example of such a model is ‘first-passage percolation’, which was introduced in [HW] (this includes the Eden model, up to a time change). A quite good shape theorem for first-passage percolation is known (see [Ki], [CD], [Ke]). In more recent first-passage percolation papers even sharper information has been obtained which gives estimates on the rate at which \( (1/t)B(t) \) converges to its limit \( B_0 \) (see [Ho] for a survey of such results).
Shape theorems for quite a few variations of Richardson’s model and first-passage percolation have been proven (see for instance [BG] and [GM]), but as far as we know these are all for models in which the cells do not move over time, with one exception. This exception is the so-called frog model which follows the rules given in our abstract, but which has \( D_A = 0 \), i.e., the susceptibles or type \( A \) cells stand still (see [AMP] and [RS] for this model). The present paper may be the first one which allows both types of particles to move.

In nearly all cases shape theorems are proven by means of Kingman’s subadditive ergodic theorem (see [Ki]). This is also what is used for the frog model. For this model one can show that the family of random variables \( \{ T_{x,y} \} \) is subadditive, were \( T_{x,y} \) is a version of the first time a particle at \( y \) is infected, if one starts with one infected particle at \( x \) and one susceptible at each other site. More precisely, the \( T_{x,y} \) can all be defined on one probability space such that \( T_{x,z} \leq T_{x,y} + T_{y,z} \) for all \( x, y, z \in \mathbb{Z}^d \) and such that their joint distribution is invariant under translations. Unfortunately this subadditivity property is no longer valid if one allows both types of particles to move. Nevertheless, subadditivity methods are still heavily used in the proof of Theorem 1. However, we now use subadditivity only for certain ‘half-space’ processes which approximate the true process. Moreover, these half-space processes have only approximate superconvolutive properties (in the terminology of [Ha]). There is no obvious family of random variables with properties like those of the \( T_{x,y} \). One only has some relation between the distribution functions of the \( H(t, u) \) for a fixed unit vector \( u \), where \( H(t, u) \) is basically the maximum of \( \langle x, u \rangle \) over all \( x \) which have been reached by a \( B \)-particle by time \( t \) \( \langle x, u \rangle \) is the inner product of \( x \) and \( u \); for technical reasons \( H(t, u) \) will be calculated in a process in which the starting conditions are slightly different from our original process). These properties are strong enough to show that for each unit vector \( u \) there exists a constant \( \lambda(u) \) such that almost surely

\[
\lim_{n \to \infty} \frac{1}{t} H(t, u) = \lambda(u),
\]

(1.4)

Thus the \( B \)-particles reach in time \( t \) half-spaces in a fixed direction \( u \) at distances which grow linearly in \( t \). Except in dimension 1, it then still requires a considerable amount of technical work to go from this result about the linear growth of the distances of reached half-spaces to the full asymptotic shape result. We will give more heuristics before some of our lemmas.

**Remark 2.** Our proof in [KSB] shows that the right hand inclusion in (1.1) remains valid for arbitrary jumpsrates of the \( A \) and the \( B \)-particles. However, it is still not known whether the left hand inclusion holds in general. The lower bound for \( B(t) \) is known only when \( D_A = D_B \), or when \( D_A = 0 \), that is, when the \( A \) and \( B \)-particles move according to the same random walk (see [KSB]), or in the frog model, when the \( A \)-particles stand still (see [AMP],[RS]).

Here is some general notation which will be used throughout the paper. \( \|x\| \) without subscript denotes the \( \ell^\infty \)-norm of a vector \( x = (x(1), \ldots, x(d)) \in \mathbb{R}^d \), i.e.,

\[
\|x\| = \max_{1 \leq i \leq d} |x(i)|.
\]
We will also use the Euclidean norm of $x$; this will be denoted by the usual $\|x\|_2$. $\langle x, u \rangle$ denotes the (Euclidean) inner product of two vectors $x, u \in \mathbb{R}^d$, and $\mathbf{0}$ denotes the origin (in $\mathbb{Z}^d$ or $\mathbb{R}^d$). For an event $\mathcal{E}$, $\mathcal{E}^c$ denotes its complement.

$K_1, K_2, \ldots$ will denote various strictly positive, finite constants whose precise value is of no importance to us. The same symbol $K_i$ may have different values in different formulae. Further, $C_i$ denotes a strictly positive constant whose value remains the same throughout this paper. a.s. is an abbreviation of almost surely.

Acknowledgement. The research for this paper was started during a stay by H. Kesten at the Mittag-Leffler Inst. in 2001-2002. H. Kesten thanks the Swedish Research Council for awarding him a Tage Erlander Professorship for 2002. Further support for HK came from the NSF under Grant DMS 9970943 and from Eurandom. HK thanks Eurandom for appointing him as Eurandom Professor in the fall of 2002. He also thanks the Mittag-Leffler Inst. and Eurandom for providing him with excellent facilities and for their hospitality during his visits.

V. Sidoravicius thanks Cornell University and the Mittag-Leffler Institute for their hospitality and travel support. His research was supported by FAPERJ Grant E-26/151.905/2001, CNPq (Pronex).

2. Results from [Ksb].

Throughout the rest of this paper we assume that

\[ D_A = D_B \] (2.1)

and we abbreviate their common value to $D$. We begin this section with some further facts about the setup. We concentrate on the special case $D_A = D_B$. More details can be found in Section 2 of [Ksb] which deals with the construction of our particle system. $\{S_t\}_{t \geq 0}$ will be a continuous time simple random walk on $\mathbb{Z}^d$ with jump rate $D$ and starting at $\mathbf{0}$. To each initial particle $\rho$ is assigned a path $\{\pi_A(t, \rho)\}_{t \geq 0}$ which is distributed like $\{S_t\}_{t \geq 0}$. The paths $\pi_A(\cdot, \rho)$ for different $\rho$’s are independent and they are all independent of the initial $N_A(x, 0-), x \in \mathbb{Z}^d$. The position of $\rho$ at time $t$ equals $\pi(0, \rho) + \pi_A(t, \rho)$, and this can be assigned to $\rho$ without knowing the paths of any of the other particles. The type of $\rho$ at time $s$ is denoted by $\eta(s, \rho)$. This equals $A$ for $0 \leq s < \theta(\rho)$ and equals $B$ for $s \geq \theta(\rho)$, where $\theta(\rho)$, the so-called switching time of $\rho$, is the first time at which $\rho$ coincides with an initial $B$-particle. Note that this is simpler than in the construction of [Ksb] for the general case which may have $D_A \neq D_B$. In that case we had simple random walks $\{S^n_t\}_{t \geq 0}$ with jump rate $D_\eta$ for $\eta \in \{A, B\}$, and there were two paths associated with each initial particle $\rho : \pi_\eta(\cdot, \rho), \eta \in \{A, B\}$, with $\{\pi_\eta(t, \rho)\}$ having the same distribution as $\{S_t\}$. If $\rho$ had initial position $z$, its position was then equal to $z + \pi(0, \rho) + \pi_A(t, \rho)$ until $\rho$ first coincided with a $B$-particle at time $\theta(\rho)$; for $t \geq \theta(\rho)$ the position of $\rho$ was $z + \pi_A(\theta(\rho), \rho) + [\pi_B(t, \rho) - \pi_B(\theta(\rho), \rho)]$. This depends on $\theta(\rho)$ and therefore on the movement of all the other particles. In the present case we can take $\pi_B = \pi_A$, which has the great advantage that the path of $\rho$ does not depend on the paths of the other particles. This is the reason why the case $D_A = D_B$ is special. We proved in [Ksb] that on a certain state space $\Sigma_0$, the collection of positions and types of all particles
at time $t$, with $t$ running from 0 to $\infty$, is well defined and forms a strong Markov process with respect to the $\sigma$-fields $F_t = \cap_{h>0} F_{t+h}$, $t \geq 0$, where $F_t^0$ is the $\sigma$-field generated by the positions and types of all particles during $[0, t]$. The elements of these $\sigma$-fields are subsets of $\Sigma^{[0,\infty)}$, where $\Sigma = \prod_{k \geq 1} \((Z^d \cup \partial_k) \times \{A, B\}\)$. $\Sigma^{[0,\infty)}$ is the pathspace for the positions and types of all particles. More explicit definitions are given in [KSb] but are probably not needed for this paper. It was also shown in [KSb] that if one chooses the number of initial $A$-particles at $z$, with $z$ varying over $\mathbb{Z}^d$, as i.i.d. mean $\mu_A$ Poisson variables, then the process starts off in $\Sigma_0$ and stays in $\Sigma_0$ forever, almost surely.

We write $N_\eta(z,t)$ for the number of particles of type $\eta$ at the space-time point $(z,t)$, $z \in \mathbb{Z}^d, \eta \in \{A, B\}$, while $N_A(z,0-)$ denotes the number of $A$-particles to be put at $z$ “just before” the system starts evolving. Note that our model always has only particles of one type at each given site, because an $A$-particle which meets a $B$-particle changes instantaneously to a $B$-particle. Thus, if $N_A(z,0-)=N$ for some site $z$ and we add $M > 0$ $B$-particles at $z$ at time 0, then we have to say that $N_A(z,0)=0, N_B(z,0)=N+M$.

We shall rely heavily on basic upper and lower bounds for the growth of $B(t)$ which come from Theorems 1 and 2 in [KSb].

**Theorem A.** If $D_A = D_B$, then there exist constants $0 < C_2 \leq C_1 < \infty$ such that for every fixed $K$

$$P\{C(C_2t/2) \subset B(t) \subset C(2C_1t)\} \geq 1 - \frac{1}{t^K}$$

for all sufficiently large $t$.

We also have some information about the presence of $A$-particles in the regions which have already been visited by $B$-particles. The following is Proposition 3 of [KSb].

**Proposition B.** If $D_A = D_B$, then for all $K$ there exists a constant $C_3 = C_3(K)$ such that

$$P\{\text{there is a vertex } z \text{ and an } A\text{-particle at the space-time point } (z,t) \text{ while there also was a } B\text{-particle at } z \text{ at some time } \leq t - C_3[t \log t]^{1/2}\} \leq \frac{1}{t^K} \text{ for all sufficiently large } t.$$  

(2.3)

Consequently, for large $t$

$$P\{\text{at time } t \text{ there is a site in } C(C_2t/2) \text{ which is occupied by an } A\text{-particle}\} \leq \frac{2}{t^K}.$$  

(2.4)

Finally we reproduce here Lemma 15 of [KSb] which gives an important monotonicity property. We repeat that in the present setup, with the $N_A(z,0-)$ i.i.d. Poisson variables, our process a.s. has values in $\Sigma_0$ at all times (see Proposition 5 of [KSb]).
Lemma C. Assume $D_A = D_B$ and let $\sigma^{(2)} \in \Sigma_0$. Assume further that $\sigma^{(1)}$ lies below $\sigma^{(2)}$ in the following sense:

for any site $z \in \mathbb{Z}^d$, all particles present in $\sigma^{(1)}$ at $z$ are also present in $\sigma^{(2)}$ at $z$, \hspace{1cm} (2.5)

and

at any site $z$ at which the particles in $\sigma^{(2)}$ have type $A$,

the particles also have type $A$ in $\sigma^{(1)}$. \hspace{1cm} (2.6)

Let $\pi_A(\cdot, \rho)$ be the random walk paths associated to the various particles and assume that the Markov processes $\{Y_t^{(1)}\}$ and $\{Y_t^{(2)}\}$ are constructed by means of the same set of paths $\pi_A(\cdot, \rho)$ and starting with state $\sigma^{(1)}$ and $\sigma^{(2)}$, respectively (as defined in Section 2 of [KSb], but with $\pi_A(\cdot, \rho) = \pi_B(\cdot, \rho)$ for all $s, \rho$; see (2.6), (2.7) there). Then, almost surely, $\{Y_t^{(1)}\}$ and $\{Y_t^{(2)}\}$ satisfy (2.5) and (2.6) for all $t$ with $\sigma^{(i)}$ replaced by $Y_t^{(i)}$, $i = 1, 2$. In particular, $\sigma^{(1)} \in \Sigma_0$.

In particular, this monotonicity property says that if $\sigma^{(1)}$ is obtained from $\sigma^{(2)}$ by removal of some particles and/or changing some $B$-particles to $A$-particles, then the process starting from $\sigma^{(1)}$ has no more $B$-particles at each space-time point than the process starting from $\sigma^{(2)}$. We note that this monotonicity property holds only under our basic assumption that $D_A = D_B$.

3. A subadditivity relation.

In this section we shall prove a basic subadditivity relation and deduce from it that the $B$-particles spread in each fixed direction over a distance which grows asymptotically linearly with time. This statement is ambiguous because we haven’t made precise what “spread in a fixed direction” means. Here this will be measured by

$$\max\{\langle x, u \rangle : x \in \tilde{B}(t)\},$$

where $u$ is a given unit vector (in the Euclidean norm) in $\mathbb{R}^d$ (see the abstract for $\tilde{B}$). In addition we will not prove subadditivity (which is an almost sure relation), but only superconvolutivity, in the terminology of [Ha] (which is a relation between distribution functions). The tool of superconvolutivity in other models with no obvious subadditivity in the strict sense goes back to [R], and was also used in [BG] and [W].

We define the closed half-space

$$\mathcal{S}(u, c) = \{x \in \mathbb{R}^d : \langle x, u \rangle \geq c\}.$$ 

Given a $u \in S^{d-1}$ and $r \geq 0$ we consider the half-space process corresponding to $(u, -r)$ (also called $(u, -r)$ half-space-process). We define this to be the process whose initial state is of the form

$$N_A(x, 0-) = 0 \text{ if } x \notin \mathcal{S}(u, -r) \text{ and the } N_A(x, 0-), \ x \in \mathcal{S}(u, -r),$$

are i.i.d., mean $\mu_A$ Poisson variables.
In addition the particles at $x_{0, -r}$ are turned into $B$-particles at time 0, where $x_{0, -r}$ is the site in $S(u, -r)$ nearest to the origin (in $\ell^\infty$-norm) with $N_A(x_{0, -r}, 0^-) > 0$; if there are several possible choices for $x_{0, -r}$, the tie is broken according to some deterministic rule chosen in advance. There will be many other occasions were ties may occur. These will be broken in the same way as here, but we shall not mention ties or the breaking of them anymore. Note that no extra $B$-particles are introduced at time 0, but that only the type of the particles at $x_{0, -r}$ is changed. Thus,

$$N_A(x, 0) + N_B(x, 0) = N_A(x, 0^-) \text{ for all } x. \quad (3.2)$$

From time 0 on the particles move and change type as described in the abstract. Note that only the initial state is restricted to $S(u, -r)$. Once the particles start to move they are free to leave $S(u, -r)$. The $(u, -r)$ half-space process will often be denoted by $P^h(u, -r)$.

We further define the $(u, -r)$ half-space process starting at $(x, t)$. This process is defined for times $t' \geq t$ only. We define it as follows: at time $t$ let $x_{0, -r}(t)$ be the nearest site to $x$ which is occupied in the $(u, -r)$ half-space process. We then reset the types of the particles at $x_{0, -r}(t)$ to $B$ and the types of all other particles present in the $(u, -r)$ half-space process at time $t$ to $A$. The particles then move along the same path in the $(u, -r)$ half-space process starting at $(x, t)$ as in $P^h(u, -r)$ (which starts at $(0, 0)$). However, the types of the particles in the $(u, -r)$ half-space process starting at $(x, t)$ are determined on the basis of the reset types at time $t$. Thus the half-space process starting at $(x, t)$ has at any time only particles which were in $S(u, -r)$ at time 0. Moreover, at any site $y$ and time $t' \geq t$, $P^h(u, -r)$ and the $(u, -r)$ half-space process started at $(x, t)$ contain exactly the same particles. We see from this that the paths of the particles in the $(u, -r)$ half-space processes starting at $(x, t)$ and at $(0, 0)$ are coupled so that they coincide from time $t$ on, but the types of a particle in these two processes may differ. Lemma C shows that if there is a $B$-particle in $P^h(u, -r)$ at $x$ at time $t$, then in this coupling any $B$-particle in the $(u, -r)$ half-space process starting at $(x, t)$ also has to have type $B$ in $P^h(u, -r)$.

The coupling between the two half-space processes clearly relies heavily on the assumption $D_A = D_B$, so that we can assign the same path to a particle in the two processes, even though the types of the particle in the two processes may be different.

It is somewhat unnatural to start the $(u, -r)$ half-space process with $B$-particles at $x_{0, -r}$ in case $r < 0$, so that the origin does not lie in the half-space $S(u, -r)$. We shall avoid that situation. We can, however, use the $(u, -r)$ half-space process starting at $(x, t)$. This is well defined for all $r$. We merely need to find the site nearest to $x$ which has at time $t$ a particle which started in $S(u, -r)$ at time 0. We can then reset the type of the particles at this site to $B$ at time $t$. We shall consider the $(u, -r)$ half-space process starting at $(x, t)$ mostly in cases where we already know that $x$ itself is occupied at time $t$ in the $(u, -r)$ half-space process.

Finally we shall occasionally talk about the full-space process and the full-space process starting at $(x, t)$. These are defined just as the half-space processes, but
with $r = \infty$. In particular, the full-space process starts with $B$-particles only at the nearest occupied site to the origin and (3.2) applies. The full-space process starting at $(x, t)$ has $B$-particles at time $t$ only at the nearest occupied site to $x$. The type of all particles at other sites are reset to $A$ at time $t$. By stationarity in time, the full-space process started at $(x, t)$ has $B$-particles at time $t$ only at the nearest occupied site to $x$. The type of all particles at other sites are reset to $A$ at time $t$. By stationarity in time, the full-space process started at $(x, t)$ has the same distribution at the space-time point $(x + y, t + s)$ as the full-space process (started at $(0, 0)$) at the point $(y, s)$. Again we shall use the same random walk paths $\pi_A$ for all the full state processes and the half-space processes, so that these processes are automatically coupled. We shall denote the full-space process by $P_f$.

We point out that if $0 \leq r_1 \leq r_2$, and if $\|x_{0, -r}\| \leq r_1/\sqrt{d}$, then $x_{0, -r} \in S(u, -r_1) \subset S(u, -r_2)$. In this case, both $P^h(u, -r_1)$ and $P^h(u, -r_2)$ start with changing the type to $B$ at the site $x_{0, -r}$ only. By Lemma C, at any time

$$\text{any } B\text{-particle in } P^h(u, -r_1) \text{ is also a } B\text{-particle in } P^h(u, -r_2).$$

This comment also applies if $P^h(u, -r_2)$ is replaced by $P_f$ (which is the case $r_2 = \infty$).

It seems worthwhile to discuss more explicitly the relation of the full-space process to our process as described in the abstract. The latter has some $B$-particles introduced at time 0 at one or more sites, in addition to the Poisson numbers of particles, $N_A(x, 0-), x \in \mathbb{Z}^d$. If exactly one $B$-particle is added at time 0, and this particle is placed at $0$, then we shall call the resulting process the original process.

Suppose we want to estimate $P\{A(x_0)\}$ in the full-space process, where

$$x_0 := \text{the nearest occupied site to the origin at time 0 in } P_f,$$

$A$ is some event and $A(x)$ is the translation by $x$ of this event (which takes $N_A(0, s)$ to $N_A(x, s)$). Then, for $C$ a subset of $\mathbb{Z}^d$,

$$P\{x_0 \in C, A(x_0) \text{ in } P_f\} = \sum_{x \in C} P\{x_0 = x, A(x)\}$$

$$\leq \sum_{x \in C} P\{x \text{ is occupied at time 0, } A(x) \text{ in } P_f\}$$

$$= \sum_{x \in C} \sum_{k=1}^{\infty} e^{-\mu_A} \frac{[\mu_A]^k}{k!} P\{A|\text{there are } k \text{ B-particles at } 0 \text{ at time 0}\}. (3.5)$$

(The probability in the last sum is the same in $P_f$ as in the original process.) On the other hand, in the original process we have

$$P\{A \text{ in original process}\}$$

$$= \sum_{k=1}^{\infty} e^{-\mu_A} \frac{[\mu_A]^{k-1}}{(k-1)!} P\{A|\text{there are } k \text{ B-particles at } 0 \text{ at time 0}\}. (3.6)$$
Comparison of the right hand sides in (3.5) and (3.6) yields the crude bound

\[ P\{x_0 \in C, A(x_0) \text{ in the full-space process}\} \leq (\text{cardinality of } C) \mu_A P\{A \text{ in original process}\}. \]  

(3.7)

We shall repeatedly use a somewhat more general version of this inequality (see for instance (3.25), (3.77), (3.78), (5.33)). Suppose \( s \geq 0 \) is fixed and \( X \) is a random vertex in \( \mathbb{Z}^d \), and suppose further that

\[ P\{\text{in } \mathcal{P}^f, A(X) \text{ but } (X, s) \text{ is not occupied}\} = 0. \]  

(3.8)

(Note that this is satisfied if \( (X, s) \) is occupied almost surely in \( \mathcal{P}^f \).) Let \( C \subset \mathbb{Z}^d \) as before. Now, given that there are \( k \geq 1 \) particles at the (non-random) space-time point \( (x, s) \), the full-space process starting at \( (x, s) \) is simply a translation by \( (x, s) \) in space-time of the original process, conditioned to start with \( k - 1 \) points at the origin and one \( B \)-particle added at the origin. Therefore, essentially for the same reasons as for (3.7),

\[ P\{X \in C, A(X) \text{ in the full-space process starting at } (X, s)\} \leq (\text{cardinality of } C) \mu_A P\{A \text{ in original process}\}. \]  

(3.9)

For a rather trivial comparison in the other direction we note that if \( P\{A \in \mathcal{P}^f\} = 0 \) for the full-space process, then we certainly have for each \( k \geq 1 \) that

\[ 0 = P\{A \in \mathcal{P}^f, x_0 = 0, k \text{ particles at } x_0\} = e^{-\mu_A} \frac{[\mu_A]^k}{k!} P\{A | \text{there are } k \text{ } B\text{-particles at } 0 \text{ at time } 0\}. \]  

(3.10)

This implies, via (3.6) that also \( P\{A \in \mathcal{P}^f\} = 0 \).

It is somewhat more complicated to compare \( \mathcal{P}^f \) with the process described in the abstract if more than one \( B \)-particle is introduced at time 0. Rather than develop general results in this direction we merely show in our first lemma that it suffices to prove (1.3) for the full-space process.

**Lemma 1.** If (1.3) holds in \( \mathcal{P}^f \), then it also holds in the original process of the abstract with any fixed finite number of \( B \)-particles added at time 0.

**Proof.** The preceding discussion shows that if (1.3) has probability 1 in \( \mathcal{P}^f \), then it has probability 1 in the original process (with one particle added at the origin at time 0). By translation invariance (1.3) will then have probability 1 in the process of the abstract with one particle added at any fixed site at time 0.

Lemma C implies that one can couple two processes as in the abstract, with collections of \( B \)-particles \( A^{(1)} \subset A^{(2)} \) added at time 0, respectively, in such a way that the process corresponding to \( A^{(1)} \) always has no more \( B \)-particles than the
one corresponding to $A^{(2)}$. Therefore, if the left hand inclusion in (1.3) holds when only one $B$-particle is added at time 0, then it certainly holds if more than one $B$-particle are added.

It follows that we only have to prove the right hand inclusion in (1.3) for the process from the abstract with more than one particle added, if we already know it when exactly one particle is added. Assume first that we run this last process with one $B$-particle $\rho_0$ added at $z_0$. We now have to refer the reader to the genealogical paths introduced in the proof of Proposition 5 of [Ksb]. The right hand inclusion in (1.3) then says that for all $\varepsilon > 0$

\[ P\{ \text{there exist genealogical paths from } z_0 \text{ to some point outside } (1 + \varepsilon)tB_0 \text{ for arbitrarily large } t \} = 0. \tag{3.11} \]

From the construction of the genealogical paths in Proposition 5 of [Ksb] and the fact that a.s. there are only finitely many $B$-particles at finite times (see (2.18) in [Ksb]) it is not hard to deduce that

\[
\{ \tilde{B}(t) \not\subset (1 + \varepsilon)tB_0 \text{ at time } t \text{ if one adds a } B\text{-particle } \rho_i \\
\text{ at } z_i, \ 1 \leq i \leq k, \text{ at time } 0 \}
= \{ \text{there is a genealogical path from some } z_i, \ 1 \leq i \leq k, \\
\text{ to the complement of } (1 + \varepsilon)tB_0 \text{ at time } t \text{ if one} \\
\text{ adds a } B\text{-particle } \rho_i \text{ at } z_i, \ 1 \leq i \leq k, \text{ at time } 0 \} \]

\[
\subset \bigcup_{i=1}^{k} \{ \text{there is a genealogical path from } z_i \text{ to the complement of} \\
(1 + \varepsilon)tB_0 \text{ at time } t \text{ if one adds a } B\text{-particle } \rho_i \text{ at } z_i \text{ at time } 0 \} \tag{3.12}
\]

(the $z_i$ do not have to be distinct here). It follows that

\[
P\{ \tilde{B}(t) \not\subset (1 + \varepsilon)tB_0 \text{ for arbitrarily large times } t \text{ if one} \\
\text{ adds a } B\text{-particle } \rho_i \text{ at } z_i, \ 1 \leq i \leq k, \text{ at time } 0 \}
\leq \sum_{i=1}^{k} P\{ \text{there are genealogical paths from } z_i \text{ to the complement of } (1 + \varepsilon)tB_0 \\
\text{ at arbitrarily large times } t \text{ if one adds a } B\text{-particle } \rho_i \text{ at } z_i \text{ at time } 0 \}
= 0 \text{ (by (3.11)).}
\]

Thus the right hand inclusion in (1.3) holds a.s., even if one adds $k$ $B$-particles at time 0. \hfill \blacksquare

We recall that

\[ \mathcal{P}^h(u, -r) \text{ is short for the } (u, -r) \text{ half-space process,} \]
$P^f$ is short for the full-space process,

and we further introduce

$$B^h(y, s; u, -r) := \{\text{there is a } B\text{-particle at } (y, s) \text{ in } P^h(u, -r)\}, \quad (3.13)$$

$$h(t, u, -r) = \max\{\langle x, u \rangle : B^h(x, t; u, -r) \text{ occurs}\}. \quad (3.14)$$

$P^{or}$ will denote the probability measure for the original process (with one $B$-particle added at the origin at time 0); $E^{or}$ is expectation with respect to $P^{or}$. (The superscripts $h, f$ and or are added to various symbols which refer to a half-space process, the full-space process, or the original process, respectively). We use $P$ without superscript if it is clear from the context with which process we are dealing or when we are discussing the probability of an event which is described entirely in terms of the $N_A(x, 0-)$ and the paths $\pi_A$.

The following technical lemma will be useful. It tells us that, with high probability, $P^h(u, -r)$ moves out in the direction of $u$ at least at the speed $C_4$, provided $r$ is large enough (see (3.15)). Its proof would be nicer if we made use of the fact that even the $(u, 0)$ half-space-process has, with a probability at least $1 - t^{-K}$, $B$-particles at time $t$ at sites $x$ with $\langle x, u \rangle \geq Ct$, for some constant $C > 0$. However, it takes some work to prove this fact and we decided to do without it. The lemma itself is proven by recursively constructing a sequence of space-time points which move out in the direction of $u$ along an exponentially growing sequence, so that there is only an exponentially small (in $k$) probability that the $k$-th point is not occupied in the $(u, -r)$ half-space process.

**Lemma 2.** Let $C_1, C_2$ be as in Theorem A and let

$$C_4 = \frac{2\sqrt{dC_1 C_2}}{32\sqrt{dC_1} + C_2}. \quad (3.15)$$

For all constants $K \geq 0$, there exists a constant $r_0 = r_0(K) \geq 0$ such that for $r \geq r_0$

$$P\left\{h(t, u, -r) \leq C_4 t \text{ for some } t \geq t_1 := \frac{1}{4\sqrt{dC_1}} \left[1 + \frac{C_2}{32\sqrt{dC_1}}\right] r\right\} \leq r^{-K}. \quad (3.16)$$

**Proof.**

**Step 1.** For $k \geq 1$ define the times

$$t_k = \frac{1}{4\sqrt{dC_1}} \left[1 + \frac{C_2}{32\sqrt{dC_1}}\right]^k r,$$

and the real numbers

$$d_k = \frac{C_2}{32\sqrt{dC_1}} \left[1 + \frac{C_2}{32\sqrt{dC_1}}\right]^k r.$$
Also define for each \( k \geq 1 \) the event
\[
\mathcal{D}_k := \{ \mathcal{B}^h(x_k, t_k; u, -r) \text{ occurs for some } x_k \text{ which satisfies } \langle x_k, u \rangle \geq d_k \text{ and } \|x_k\| \leq 2C_1 t_k \}.
\] (3.17)

In this step we shall reduce the lemma to an estimate for the probability that \( \mathcal{D}_k \) fails for some \( k \geq 1 \). Indeed, assume that \( \mathcal{D}_k \) occurs for all \( k \geq 1 \). By definition, there is then a \( B \)-particle at \((x_k, t_k)\) in the \((u, -r)\) half-space process (starting at \((0, 0)\)), so that
\[
h(t_k, u, -r) \geq \langle x_k, u \rangle \geq d_k = \frac{C_2}{32 \sqrt{dC_1}} \left[ 1 + \frac{C_2}{32 \sqrt{dC_1}} \right]^k r, \quad k \geq 1.
\] (3.18)
Recall that \( \mathcal{F}_t \) is defined in the beginning of Section 2. In addition to (3.18), we have on the event \( \{\langle x_k, u \rangle \geq d_k\} \), for \( k \geq 1 \),
\[
P\{h(t, u, -r) \leq \frac{1}{2}d_k \text{ for some } t \in [t_k, t_{k+1})|\mathcal{F}_t\}
\leq P\{\text{each } B\text{-particle in } \mathcal{P}^h(u, -r) \text{ at } (x_k, t_k) \text{ moves during } [t_k, t_{k+1}] \text{ to some site } x \text{ with } \langle x, u \rangle \leq \frac{1}{2}d_k\}
\leq P\{\min_{q=t_{k+1}+t_k} \langle S_q, u \rangle \leq -\frac{1}{2}d_k = -C_4 t_{k+1}\}
\leq K_1 \exp[-K_2 t_{k+1}]
\] (3.19)
for some constants \( K_1, K_2 \) depending on \( d, D_A \) only; see (2.42) in [KSa] for the last inequality. It follows that the left hand side of (3.16) is bounded by
\[
P\{\mathcal{D}_k \text{ fails for some } k \geq 1\} + \sum_{k=1}^{\infty} K_1 \exp[-K_2 t_k].
\] (3.20)

**Step 2.** We shall now derive a recursive bound for \( \cap_{1 \leq j \leq k} \mathcal{D}_j \). Assume that \( \cap_{1 \leq j \leq k-1} \mathcal{D}_j \) occurs for some \( k \geq 2 \). Consider now the full-space process starting at \((x_{k-1}, t_{k-1})\). Define the following events for this process:
\[
\mathcal{E}_{k,1} := \{ \text{at time } t_k \text{ all occupied sites in } x_{k-1} + \mathcal{C}(\langle C_2/2 \rangle (t_k - t_{k-1})) \text{ contain in fact a } B\text{-particle}\},
\]
\[
\mathcal{E}_{k,2} := \{ \text{at time } t_k \text{ there is an occupied site in } x_{k-1} + (\langle C_2/4 \rangle (t_k - t_{k-1}) u + \mathcal{C}(|\log t_k|^2))\},
\]
\[
\mathcal{E}_{k,3} := \{ \text{all particles in } x_{k-1} + \mathcal{C}(2C_1(t_k - t_{k-1})) \text{ at time } t_{k-1} \text{ started at time } 0 \text{ in } \mathcal{S}(u, -r)\},
\]
\[
\mathcal{E}_{k,4} := \{ \text{there is no } B\text{-particle outside } x_{k-1} + \mathcal{C}(C_1(t_k - t_{k-1})) \text{ during } [t_{k-1}, t_k]\},
\]
\[
\mathcal{E}_{k,5} := \{ \text{no particle which is outside } x_{k-1} + \mathcal{C}(2C_1(t_k - t_{k-1})) \text{ at time } t_{k-1} \text{ enters } x_{k-1} + \mathcal{C}(C_1(t_k - t_{k-1})) \text{ during } [t_{k-1}, t_k]\},
\]
We claim that on
\[ \mathcal{D}_{k-1} \cap \bigcap_{1 \leq i \leq 5} \mathcal{E}_{k,i} \] (3.21)
also \( \mathcal{D}_k \) occurs, provided \( r \geq \) some suitable \( r_1 \), independent of \( k \), and \( k \geq 2 \). We merely need to make sure that \( \sqrt{d} |\log t_k|^2 \leq (C_2/8)(t_k - t_{k-1}) \) whenever \( r \geq r_1 \). To prove our claim when \( k \geq 2 \), observe first that the occurrence of \( \mathcal{E}_{k,1} \cap \mathcal{E}_{k,2} \) guarantees that at time \( t_k \) there is a \( B \)-particle at some \( x_k \) in \( x_{k-1} + (C_2/4)(t_k - t_{k-1}) \). Thus, whether the particle at \( (x_k, u) \) is a \( B \)-particle in the full-space process starting at \( (x_{k-1}, t_{k-1}) \). This will prove our claim, because the monotonicity property of Lemma C implies that any \( B \)-particle at time \( t_k \) is a \( B \)-particle in the full-space process starting at \( (x_{k-1}, t_{k-1}) \). We are going to show that, in fact, it is also a \( B \)-particle in the \((u, -r)\) half-space process starting at \( (x_{k-1}, t_{k-1}) \). This will prove our claim, because the monotonicity property of Lemma C implies that any \( B \)-particle in the \((u, -r)\) half-space process starting at \( (x_{k-1}, t_{k-1}) \) is also a \( B \)-particle in the \((u, -r)\) half-space process (starting at \((0, 0)\)), provided that there is a \( B \)-particle at \( (x_{k-1}, t_{k-1}) \) in the \((u, -r)\) half-space process. (Note that this proviso is satisfied by the induction assumption that \( \mathcal{D}_{k-1} \) occurred.) We first observe that the particle at \( (x_k, t_k) \) must at time \( t_{k-1} \) have been in \( x_{k-1} + \mathcal{C}(2C_1(t_k - t_{k-1})) \), because \( x_k \in x_{k-1} + \mathcal{C}((C_2/2)(t_k - t_{k-1})) \subset x_{k-1} + \mathcal{C}((C_1/2)(t_k - t_{k-1})) \) and \( \mathcal{E}_{k,5} \) occurs. By virtue of \( \mathcal{E}_{k,3} \) this particle then belongs to \( \mathcal{P}^h(u, -r) \) as well as to the \((u, -r)\) half-space process starting at \( (x_{k-1}, t_{k-1}) \). We still have to show that this particle also has type \( B \) in the \((u, -r)\) half-space process starting at \( (x_{k-1}, t_{k-1}) \). To this end we note that the particles starting outside \( x_{k-1} + \mathcal{C}(2C_1(t_k - t_{k-1})) \) at time \( t_{k-1} \) do not influence the type of any particle at time \( t_k \) in the full-space process starting at \( (x_{k-1}, t_{k-1}) \). Indeed, in this process the particles outside \( x_{k-1} + \mathcal{C}(2C_1(t_k - t_{k-1})) \) start as \( A \)-particles, and since \( \mathcal{E}_{k,4} \cap \mathcal{E}_{k,5} \) occurs, these particles do not meet any \( B \)-particle at or before time \( t_k \). Thus, whether the particle at \( (x_k, t_k) \) is also a \( B \)-particle in the \((u, -r)\) half-space process starting at \( (x_{k-1}, t_{k-1}) \) depends only on the paths of the particles which were in \( x_{k-1} + \mathcal{C}(2C_1(t_k - t_{k-1})) \) at time \( t_{k-1} \) (compare the lines following (2.37) in [KSb]). All these particles were particles in \( \mathcal{P}^h(u, -r) \) at time \( t_{k-1} \) (on \( \mathcal{E}_{k,3} \)), and hence also are in this half-space process at time \( t_k \). Thus the type of the particle at \( (x_k, t_k) \) is the same in the full-space process starting at \( (x_{k-1}, t_{k-1}) \) and in the \((u, -r)\) half-space process starting at \( (x_{k-1}, t_{k-1}) \). This justifies our claim that \( \mathcal{D}_k \) occurs for \( k \geq 2 \). We leave it to the reader to make some simple modifications in the above argument to show that \( \mathcal{D}_1 \) occurs on
\[ \mathcal{D}_0 \cap \bigcap_{1 \leq i \leq 5} \mathcal{E}_{1,i}, \]
where
\[ t_0 = 0 \] and \( \mathcal{D}_0 = \{ \|x_0\| \leq K_3 \log r \} \).
provided \( r_i \) is chosen large enough; \( x_0 \) is defined in (3.4) and \( K_3 \) is chosen right after (3.25) and depends on \( K, d \) and \( \mu_A \) only.

We have now shown that on the event (3.21) also \( D_k \) occurs. If this is the case and also \( \cap_{1 \leq i \leq 5} E_{k+1,i} \) occurs, then \( D_{k+1} \) occurs etc. Consequently, for \( r \geq r_1 \),

\[
P\{D_0 \text{ occurs, but some } D_k \text{ fails}\} \leq \sum_{i=1}^{5} P\{\text{for some } x_0 \text{ with } \|x_0\| \leq K_3 \log r, x_0 \text{ is occupied but } E_{1,i} \text{ fails}\} + \sum_{k=2}^{\infty} \sum_{i=1}^{5} P\{\text{for some } x_{k-1} \text{ with } \|x_{k-1}\| \leq 2C_1 t_{k-1} \text{ and } \langle x_{k-1}, u \rangle \geq d_{k-1}, B^h(x_{k-1}, t_{k-1}; u, -r) \text{ occurs, but } E_{k,i} \text{ fails}\}. \tag{3.23}
\]

**Step 3.** In this step we shall give most of the estimates for the terms in the right hand side here for \( k \geq 2 \). The basic inequalities remain valid for \( k = 1 \) by trivial modifications which we again leave to the reader. For the various estimates we have to take all \( t_k \) large. This will automatically be the case if \( r \) is large; we shall not explicitly mention this in the estimates below.

We start with the estimate for the failure of \( E_{k,1} \). If \( E_{k,1} \) fails, for a given \( (x_{k-1}, t_{k-1}) \), then there must be some \( y \in x_{k-1} + C((C_2/2)(t_k - t_{k-1})) \) such that \( y \) is occupied by an \( A \)-particle at time \( t_k \) in the full-space process started at \( (x_{k-1}, t_{k-1}) \). Recall that if we shift the full-space process starting at \( (x, t) \) by \( (-x, -t) \) in space-time, then we obtain the full state process starting at \( (0, 0) \). Moreover, if we condition on the event that \( x \) is occupied at time \( t \), then, after the shift by \( (-x, -t) \) the \( N_A(y, 0) \), \( y \neq 0 \), are i.i.d. mean \( \mu_A \) Poisson random variables. Therefore, by summing over the possible values for \( x_{k-1} \),

\[
P\{\text{for some } x_{k-1} \text{ with } \|x_{k-1}\| \leq 2C_1 t_{k-1} \text{ and } \langle x_{k-1}, u \rangle \geq d_{k-1}, B^h(x_{k-1}, t_{k-1}; u, -r) \text{ occurs, but } E_{k,1} \text{ fails}\} \leq \sum_{\|x\| \leq 2C_1 t_{k-1}} P\{B^h(x, t_{k-1}; u, -r) \text{ occurs and in the full-space process started at } (x, t_{k-1}) \text{ there is an } A \text{-particle in } x + C((C_2/2)(t_k - t_{k-1})) \text{ at time } t_k\} \leq \sum_{\|x\| \leq 2C_1 t_{k-1}} P\{0 \text{ is occupied at time } 0 \text{ and in } \mathcal{P}^I \text{ there is an } A \text{-particle in } C((C_2/2)(t_k - t_{k-1})) \text{ at time } t_k - t_{k-1}\}.
\]

To the right hand side here we can apply (3.7) (with \( C = \{0\} \)). This shows that the right hand side is at most

\[
K_A[t_{k-1}]^d \mu_A P^{or}\{\text{at time } t_k - t_{k-1}, \text{ there is an } A \text{-particle in } C((C_2/2)(t_k - t_{k-1}))\}.
\]

The probability in the right hand side here is calculated for the original process with one particle added at \( 0 \) at time 0. By (2.4) (with \( K \) replaced by \( K + d + 2 \))
this probability is at most \(2[t_k - t_{k-1}]^{-K-d-2}\). Therefore,

\[
P\{\text{for some } x_{k-1} \text{ with } \|x_{k-1}\| \leq 2C_1 t_{k-1} \text{ and } \langle x_{k-1}, u \rangle \geq d_{k-1},
\]

\[
B^h(x_{k-1}, t_{k-1}; u, -r) \text{ occurs, but } \mathcal{E}_{k,1} \text{ fails}\}
\]

\[
\leq 2K_4[t_{k-1}]^d \mu_A[t_k - t_{k-1}]^{-K-d-2} \leq K_5 t_k^{-K-2}.
\]

It turns out that in the estimates for \(\mathcal{E}_{k,2}, \mathcal{E}_{k,3}\) and \(\mathcal{E}_{k,5}\) we can ignore the type of the particle at \((x_{k-1}, t_{k-1})\); we just need that this space-time point is occupied. For \(\mathcal{E}_{k,2}\) we again shift by \((-x_{k-1}, -t_k)\), sum over the possible values of \(x_{k-1}\) and apply (3.7). This gives

\[
P\{\text{for some } x_{k-1} \text{ with } \|x_{k-1}\| \leq 2C_1 t_{k-1}, \ (x_{k-1}, t_{k-1}) \text{ is occupied but } \mathcal{E}_{k,2} \text{ fails}\}
\]

\[
\leq K_4[t_{k-1}]^d \mu_A P\{N_A(y, 0-) = 0 \text{ for all } y \in (C_2/4)(t_k - t_{k-1})u + \mathcal{C}([\log t_k]^2)\}
\]

\[
\leq t_k^{-K-2},
\]

for large \(r\), because the \(N_A(y, 0-)\) are independent.

Next, for \(\mathcal{E}_{k,3}\) we use that on \(D_{k-1}\), the distance between \(x_{k-1} + \mathcal{C}(2C_1(t_k - t_{k-1}))\) and the complement of \(S(u, -r)\) is at least

\[
\langle x_{k-1}, u \rangle + r - 2\sqrt{dC_1(t_k - t_{k-1})} \geq d_{k-1} + r - 2\sqrt{dC_1(t_k - t_{k-1})}
\]

\[
= \frac{1}{2}d_{k-1} + r.
\]

Thus, if we take the restriction \(\langle x_{k-1}, u \rangle \geq d_{k-1}\) into account we find that

\[
P\{\text{for some } x_{k-1} \text{ with } \|x_{k-1}\| \leq 2C_1 t_{k-1} \text{ and } \langle x_{k-1}, u \rangle \geq d_{k-1},
\]

\[
x_{k-1} \text{ is occupied at time } t_{k-1} \text{ but } \mathcal{E}_{k,3} \text{ fails}\}
\]

\[
\leq \sum_{\|x\| \leq 2C_1 t_{k-1}} \sum_{y \notin \mathcal{S}(u, -r)} \sum_{z \in x + \mathcal{C}(2C_1(t_k - t_{k-1}))} P\{S_{t_{k-1}} = z - y\}
\]

\[
\leq K_6 t_{k-1}^d |t_k - t_{k-1}|^d P\{\|S_{t_{k-1}}\| \geq \frac{1}{2}d_{k-1} + r\}
\]

\[
\leq K_7 t_k^{2d} \exp \left[ -K_8 \frac{(d_{k-1} + r)^2}{t_k - t_{k-1} + d_{k-1} + r} \right] \text{ (by (2.42) in \([KSa]\))}
\]

\[
\leq t_k^{-K-2}.
\]

The estimate for \(\mathcal{E}_{k,4}\) comes from Theorem A, or rather Theorem 1 in \([KSb]\), which is the basis for the right hand inclusion in Theorem A. Indeed, we have, again by summing over the possible values of \(x_{k-1}\) and using (3.9),

\[
P\{\text{for some } x_{k-1} \text{ with } \|x_{k-1}\| \leq 2C_1 t_{k-1}, \ (x_{k-1}, t_{k-1}) \text{ is occupied but } \mathcal{E}_{k,4} \text{ fails}\}
\]

\[
\leq K_4[t_{k-1}]^d \mu_A \{\text{there are } B\text{-particles outside } \mathcal{C}(C_1(t_k - t_{k-1})) \text{ at some time } t_k - t_{k-1}\}.
\]

(3.25)
To estimate the probability on the right we argue as in the proof of Theorem 3 of [Ksb]. If a particle has type $B$ at some time $s \leq t_k - t_{k-1}$ and is outside the cube $C(C_1(t_k - t_{k-1}))$ at that time, then by symmetry of the random walk $\{S\}$, the particle has a conditional probability given $\mathcal{F}_s$ at least $1/2$ of being outside $C(C_1(t_k - t_{k-1}))$ at time $t_k - t_{k-1}$. Therefore (with $E^o$ denoting expectation with respect to $P^o$),

\[
E^o \{ \text{number of particles outside } C(C_1(t_k - t_{k-1})) \text{ at some time during } [0, t_k - t_{k-1}] \} \leq 2E^o \{ \text{number of particles outside } C(C_1(t_k - t_{k-1})) \text{ at time } t_k - t_{k-1} \}.
\]

The expectation in the right hand side here is exponentially small in $(t_k - t_{k-1})$ by Theorem 1 of [Ksb] and is an upper bound for the probability in the right hand of (3.25). Thus the left hand side of (3.25) is at most $t_k - K - 2$ again.

The probability involving $\mathcal{E}_{k,5}^c$ is also $O(t_k^{-K-2})$. This can be shown by large deviation estimates for random walks, analogously to the terms involving $\mathcal{E}_{k,3}^c$.

This provides the necessary bounds of the summands in (3.23). Finally, we have

\[
P\{D_0 \text{ fails} \} \leq P\{N_A(x, 0-) = 0 \text{ for all } x \text{ with } \|x\| < K_3 \log r \} = \exp \left[ -\mu_A K_9[K_3 \log r]^d \right]. \tag{3.26}
\]

Thus we can take $K_3 = K_3(K, d, \mu_A)$ so large that the left hand side of (3.26) is at most $r^{-K-1}$ for all $r \geq 3$. (3.20), (3.26) and (3.23) together now show that the left hand side of (3.16) is for large $r$ at most

\[
K_{10}r^{-K-1} + \sum_{k=1}^{\infty} K_1 \exp[-K_2 t_k] + \sum_{k=1}^{\infty} K_{11} t_k^{-K-2} \leq K_{12}r^{-K-1}. \quad \blacksquare
\]

For any vector $v \in \mathbb{R}^d$, we define

\[
v^\perp = v^\perp(u) := v - \langle v, u \rangle u.
\]

We further introduce the following (semi-infinite) cylinders with axis in the direction of $u$, for $\alpha, \beta \in \mathbb{R}$ and $\gamma \in \mathbb{R}^d$ a vector orthogonal to $u$ (see Figure 1):

\[
\Gamma(\alpha, \beta, \gamma) = \Gamma(\alpha, \beta, \gamma, u) := \{x \in \mathbb{R}^d : \langle x, u \rangle \geq \alpha, \|x^\perp - \gamma\| \leq \beta\}
\]

and the events

\[
\mathcal{G}(\alpha, \beta, \gamma, \mathcal{P}, t) = \mathcal{G}(\alpha, \beta, \gamma, \mathcal{P}, t, u) := \{\text{in the process } \mathcal{P} \text{ there is a } B\text{-particle in } \Gamma(\alpha, \beta, \gamma) \text{ at time } t\}.
\]
The last definition will be used with $\mathcal{P}$ taken equal to some half-space, full-space or the original process.

We remind the reader that $\mathcal{P}^h(u, -r)$, the $(u, -r)$ half-space process, only uses particles which at time 0 are in the half-space $\mathcal{S}(u, -r) = \{x : \langle x, u \rangle \geq -r\}$. We shall work a great deal with the process $\mathcal{P}^h(u, -C_5 \kappa(s))$, where

$$\kappa(s) = [(s + 1) \log(s + 1)]^{1/2}$$

and $C_5$ is a constant to be determined below (see the line preceding (3.63)). We make several more definitions:

$$h^*(s, u) := h(s, u, -C_5 \kappa(s)) = \max\{\langle x, u \rangle : B^h(x, s; u, -C_5 \kappa(s)) \text{ occurs}\}$$

$$= \max\{\langle x, u \rangle : x \text{ is occupied by a } B \text{-particle in } \mathcal{P}^h(u, -C_5 \kappa(s)) \text{ at time } s\}.$$  

(3.27)
We order the sites of \( \mathbb{Z}^d \) in some deterministic way, say lexicographically, and take

\[
\ell^*(s, u) := \text{the first } x \text{ in this order for which } \mathcal{B}^h(x, s; u, -C_5\kappa(s)) \text{ occurs and which satisfies } \langle x, u \rangle = h^*(s, u).
\]

Thus, \( h^*(s, u) \) is the furthest displacement in the direction of \( u \) among the \( B \)-particles in the process \( \mathcal{P}^h(u, -C_5\kappa(s)) \) at time \( s \) and \( \ell^*(s, u) \) is the first site occupied by a \( B \)-particle in this process at time \( s \) on which this maximal displacement is reached. We shall write \( m^*(s, u) \) for \( [\ell^*(s, u)]^\perp \) so that we have the orthogonal decomposition

\[
\ell^*(s, u) = h^*(s, u)u + m^*(s, u).
\]

The following proposition contains our principal "subadditivity" property. If we take \( \beta = \infty \), that is, if we only look at its statement about displacements in the direction of \( u \), then the proposition says that (up to error terms) the maximal displacement in the direction \( u \) at time \( s + t + C_6\kappa(t) \) in the process \( \mathcal{P}^h(u, -C_5\kappa(s + t + C_6\kappa(t))) \) is stochastically larger than the sum of two independent such displacements, which are distributed like the maximal displacement in \( \mathcal{P}^h(u, -C_5\kappa(s)) \) at time \( s \) and the maximal displacement in \( \mathcal{P}^h(u, -C_5\kappa(t)) \) at time \( t \), respectively (see Corollary 5 for more details). The basic idea of the proof is that if \( \ell^* \) is a point where \( \mathcal{P}^h(u, -C_5\kappa(s)) \) achieves its maximum displacement in the direction \( u \) at time \( s \), then we can start a new half-space process "near" \( \ell^* \) which is nearly a copy of \( \mathcal{P}^h(u, -C_5\kappa(t)) \) and which is nearly independent of the first process \( \mathcal{P}^h(u, -C_5\kappa(s)) \). If we run the second process for \( t \) units of time the sum of the displacements in the direction of \( u \) in the first and second process is nearly a lower bound for the displacement of the original process at time \( s + t \).

**Proposition 3.** Let \( u \in S^{d-1}, \alpha, \beta \geq 0 \) and \( \gamma_s, \gamma_t \in \mathbb{R}^d \) orthogonal to \( u \). For any \( K > 0 \) there exist constants \( 0 < C_5 - C_8, s_0 < \infty \), which depend on \( K \), but are independent of \( u \in S^{d-1} \) and of \( \alpha, \beta, \gamma_s, \gamma_t \), such that for

\[
s_0 \leq s \leq t \text{ and } t \log t \leq C_7 s^2
\]

it holds

\[
P\{ \mathcal{G}(\alpha, \beta, \gamma_s + \gamma_t, \mathcal{P}^h(u, -C_5\kappa(s + t + C_6\kappa(t))), s + t + C_6\kappa(t)) \}
\geq \int_{0 \leq h < \infty} \int_{m \in \mathbb{R}^d} P\{ h^*(s, u) \in dh, m^*(s, u) - \gamma_s \in dm \}
\times P\{ \mathcal{G}(\alpha - h, \beta - d, \gamma_t - m, \mathcal{P}^h(u, -C_5\kappa(t)), t) \} - C_8 s^{-K-1}.
\]

**Proof.** The constants \( C_i \) and \( s_0 \) will be fixed later on. \( K_i \) will be used to denote other auxiliary constants. For the time being we only do manipulations which do
not depend on the specific value of the $C_i, K_i$. We break the proof up into three
steps. The first two steps reduce the proof of (3.31) to estimating the probabilities
of a number of small events. These estimates will be carried out in step 3.

**Step 1.** Run $P^h(u, -C_5 \kappa(s))$ till time $s$. Let $h^*(s, u) = h \in \mathbb{R}$, $\ell^*(s, u) = y \in \mathbb{Z}^d$.
Set $\overline{y} := \lfloor y + 4C_5 \kappa(t) u \rfloor$ (the meaning of this last notation is that we take the largest
integer for each coordinate separately). Next we run the $(u, \langle y, u \rangle + 2C_5 \kappa(t))$ half-
space process starting at the space-time point $(\overline{y}, s + C_6 \kappa(t))$ for $t$ units of time.
This latter half-space process will be shown to be almost an independent copy of
the translate by $(\overline{y}, s + C_6 \kappa(t))$ of $P^h(u, -C_5 \kappa(t))$. Define $z(s, t)$ to be the nearest
site in $\mathbb{Z}^d$ to $y$ which is occupied at time $s + C_6 \kappa(t)$ by a particle which started
at time 0 in the halfspace $S(u, \langle y, u \rangle + 2C_5 \kappa(t))$. It will be useful to define for general
$v \in \mathbb{Z}^d$

$$z_v = \text{the nearest site on } \mathbb{Z}^d \text{ to } v = \lfloor v + 4C_5 \kappa(t) u \rfloor \text{ which is}
\text{occupied at time } s + C_6 \kappa(t) \text{ by a particle which started}
\text{at time 0 in } S(u, \langle v, u \rangle + 2C_5 \kappa(t)). \quad (3.32)$$

Thus, $z_v$ has the same relation to $v$ as $z(s, t)$ has to $y$. In particular, $z_y = z(s, t)$.

We can now define, still for any $v \in \mathbb{Z}^d$, the sets

$$A_1(s, t) = \{x : x \text{ is occupied by one or more } B\text{-particles at time}
\text{s + t + } C_6 \kappa(t) \text{ in the process } P^h(u, -C_5 \kappa(s + t + C_6 \kappa(t)))\},$$

$$A_2(s, t, v) = \{x : x \text{ is occupied by one or more } B\text{-particles at time}
\text{s + t + } C_6 \kappa(t) \text{ in the } (u, \langle v, u \rangle + 2C_5 \kappa(t)) \text{ half-space}
\text{process starting at } (\overline{v}, s + C_6 \kappa(t))\}, \quad (3.33)$$

and

$$A_3(t) = \{x : x \text{ is occupied by one or more } B\text{-particles at time } t \text{ in}
\text{an independent copy of the process } P^h(u, -C_5 \kappa(t))\}. \quad (3.34)$$

We stress that $A_3$ is defined by means of a new copy of all initial data and paths.
It is independent of the processes we worked with so far.

Our aim is to prove the following two statements, and to show that they imply
(3.31). The first statement is that outside an event of probability at most $s^{-K-1}$
it is the case that

$$A_1(s, t) \supset A_2(s, t, y). \quad (3.34)$$

The second statement is that

$$A_1(s, t) - \overline{y} \text{ is at least as large as } A_3(t), \text{ outside}
\text{an event of probability at most } s^{-K-1} \quad (3.35)$$
(still \( y = \ell^*(s, u) \) in these relations). The relation (3.35) is stated somewhat imprecisely, but a precise version will be given below (see (3.51)). In this first step we shall reduce the proofs of (3.34) and (3.35) to a number of probability estimates.

To begin with the inclusion (3.34), we claim that this holds on the intersection of the event

\[
\{(y, u) \geq 0\} \cap \{z(s, t) \text{ is occupied by a } B\text{-particle at time } s + C_6\kappa(t) \text{ in } \mathcal{P}^h(u, -C_5\kappa(s))\}
\]

with the event (see (3.4) for \( x_0 \))

\[
\{\|x_0\| \leq K_3 \log s\}.
\]

This follows from two applications of the monotonicity property in Lemma C. Indeed, under (3.37) (and \( s \geq s_1 \) for a large enough \( s_1 \)), both the \((u, -C_5\kappa(s))\) and the \((u, -C_5\kappa(s + t + C_6\kappa(t)))\) half-space process begin with \( B \)-particles at \( x_0 \). One application of the monotonicity property therefore gives us that (under (3.37)) \( \mathcal{P}^h(u, -C_5\kappa(t + s + C_6\kappa(t))) \) has more \( B \)-particles than \( \mathcal{P}^h(u, -C_5\kappa(s)) \) at each space-time point, and therefore

\[
A_1(s, t) \supset \{x: x \text{ is occupied by one or more } B\text{-particles at time } s + t + C_6\kappa(t) \text{ in the process } \mathcal{P}^h(u, -C_5\kappa(s))\}.
\]

(3.38)

For the second application we recall that \( z(s, t) \) is occupied at time \( s + C_6\kappa(t) \) by a particle which started in \( S(u, (y, u) + 2C_5\kappa(t)) \), and in fact is the closest occupied site to \( \bar{y} \) with this property. To run the \((u, (y, u) + 2C_5\kappa(t))\) half-space process starting at \((\bar{y}, s + C_6\kappa(t))\) and to find \( A_2(s, t, y) \) we first remove all particles which at time 0 were in the halfspace \( \{x: (x, u) < (y, u) + 2C_5\kappa(t)\} \). After that we reset to \( A \) the types of all particles not at \( z(s, t) \) at time \( s + C_6\kappa(t) \) and give all particles at \( z(s, t) \) type \( B \). Note that in the first step all particles which do not belong to \( \mathcal{P}^h(u, -C_5\kappa(s)) \) are removed, since

\[
-C_5\kappa(t) \leq 2C_5\kappa(t) \leq \langle y, u \rangle + 2C_5\kappa(t) \text{ (on (3.36))}.
\]

Thus, (at time \( s + C_6\kappa(t) \)) after both steps, all remaining particles are also in \( \mathcal{P}^h(u, -C_5\kappa(s)) \), and the particles which have type \( B \), i.e., only the particles at \( z(s, t) \), also have type \( B \) in \( \mathcal{P}^h(u, -C_5\kappa(s)) \) (still on the event (3.36)). By virtue of the monotonicity property of Lemma C, at time \( s + t + C_6\kappa(t) \), any \( B \)-particle present in the \((u, (y, u) + 2C_5\kappa(t))\) half-space process starting at \((\bar{y}, s + C_6\kappa(t))\) is also a \( B \)-particle in \( \mathcal{P}^h(u, -C_5\kappa(s)) \). Therefore, on the event (3.36),

\[
A_2(s, t, y) \subset \{x: x \text{ is occupied by one or more } B\text{-particles at time } s + t + C_6\kappa(t) \text{ in the process } \mathcal{P}^h(u, -C_5\kappa(s))\}.
\]

(3.39)
Combining (3.38) and (3.39) gives (3.44) on the intersection of the events (3.36) and (3.37). We postpone the proof that this intersection indeed has probability at least \(1 - s^{-K-1}\) to step \(3\).

To prove for the desired precise form of (3.35) we shall prove that there exist constants \(K_1\) and \(s_2\) such that for \(t \geq s \geq s_2\), \(A\) any non-random subset of \(\mathbb{Z}^d\), and any fixed \(v \in \mathbb{Z}^d\),

\[
P\{A_2(s, t, v) \text{ intersects } N\} \geq P\{(\overline{v} + A_3(t)) \text{ intersects } N\} - K_1 t^{-K-d-1}. \tag{3.40}
\]

To prove this inequality we remind the reader that \(A_2(s, t, v)\) is the collection of sites where \(B\)-particles are present at time \(s + t + C_6 \kappa(t)\), if one starts at time \(s + C_6 \kappa(t)\) in the state obtained by removing the particles which started outside \(S(u, \langle v, u \rangle + 2C_5 \kappa(t))\) at time 0, and by resetting all particles not at \(z_v\) to type \(A\), while setting the type of the particles at \(z_v\) to \(B\). To find the distribution of \(A_2(s, t, v)\) we must first describe the state at time \(s + C_6 \kappa(t)\) (after the removal of particles and resetting of types) in some more detail. First let us look how many particles there are at the various sites, irrespective of their type. We began at time 0 with \(N_A(w, 0-)\) particles at \(w\), for \(w \in S(u, \langle v, u \rangle + 2C_5 \kappa(t))\) and with 0 particles at any \(w\) outside \(S(u, \langle v, u \rangle + 2C_5 \kappa(t))\). The \(N_A(w, 0-)\) are i.i.d. mean \(\mu_A\) Poisson random variables. We let these particles perform their random walks till time \(s + C_6 \kappa(t)\). Let us write \(\hat{N}(w, s + C_6 \kappa(t))\) for the number of particles (of either type) at \(w\) at this time. By properties of the Poisson distribution, all the \(\hat{N}(\overline{v} + w, s + C_6 \kappa(t)), w \in \mathbb{Z}^d\), are still independent Poisson variables, but

\[
E \hat{N}(\overline{v} + w, s + C_6 \kappa(t)) = \sum_{w' \in S(u, \langle v, u \rangle + 2C_5 \kappa(t))} \mu_A P\{S_{s+C_6 \kappa(t)} = \overline{v} + w - w'\} =: \nu(v, w, s, t). \tag{3.41}
\]

\(z_v\) is now the nearest lattice point to \(\overline{v}\) which is occupied by some particle at time \(s + C_6 \kappa(t)\). We then reset all particles not at \(z_v\) to type \(A\), and the ones at \(z_v\) to type \(B\). If we shift everything by \((-\overline{v}, -s - C_6 \kappa(t))\) (i.e., move \((w, r)\) to \((w - \overline{v}, r - s - C_6 \kappa(t))\)), then, at \((w, 0)\) we have \(M(w) := \hat{N}(\overline{v} + w, s + C_6 \kappa(t))\) particles, all of which will be reset to type \(A\), except those at \(w_0 := \) the nearest lattice site to the origin with \(M(w) > 0\). In fact, \(w_0 = z_v - \overline{v}\). The \(M(w)\) are independent Poisson variables, and \(M(w)\) has mean \(\nu(v, w, s, t)\). It follows from the definition of \(A_2(s, t, v)\) and of the \((u, \langle v, u \rangle + 2C_5 \kappa(t))\) half-space process started at \((\overline{v}, s + C_6 \kappa(t))\) that \(A_2(s, t, v) - \overline{v}\) has the distribution of

\[\{x : \text{there is a } B\text{-particle at } x \text{ at time } t \text{ in this shifted system}\}\]. \tag{3.42}

For the \(w \in S(u, -C_5 \kappa(t))\), the means \(\nu(v, w, s, t)\) are close to \(\mu_A\). In fact, it follows from (3.41) that for \(w \in S(u, -C_5 \kappa(t))\) and \(t \geq t_0 \lor s\), for some \(t_0\) (independent of
\[ \nu_A \geq \nu(v, w, s, t) \geq \mu_A \left[ 1 - \sum_{\tilde{w} : (\tilde{w}, u) \geq C_5 \kappa(t) - d} P\{S_{s+C_5\kappa(t)} = \tilde{w}\} \right] \geq \mu_A \left[ 1 - P\{(S_{s+C_5\kappa(t)}, u) \geq C_5 \kappa(t) - d\} \right] \geq \mu_A \left[ 1 - K_2 \exp[-K_3 C_5^2 \log t]\right]. \] (3.43)

for some constants \( K_2, K_3 \) that depend on \( d, D \) only (see (2.42) in [KSa] and recall that we assume (3.30)). From now on we take \( C_5 \) so large that for large \( t \)
\[ \mu_A [1 - t^{-K-2d-1}] \leq \nu(v, w, s, t) \leq \mu_A \text{ for all } w \in S(u, -C_5 \kappa(t)). \] (3.44)

It suffices for this that \( K_3 C_5^2 \geq K + 2d + 2 \). We may have to raise \( C_5 \) in the proof of (3.62) and (3.64) in step 3, but that can only improve the present estimates. With such a choice of \( C_5 \) the distribution of the particle numbers \( \{ M(w) : w \in S(u, -C_5 \kappa(t)) \cap \mathcal{C}(3C_1 t) \} \) differs in total variation from the distribution of an i.i.d. collection of mean \( \mu_A \) Poisson variables on \( S(u, -C_5 \kappa(t)) \cap \mathcal{C}(3C_1 t) \) by at most
\[ \sum_{w \in S(u, -C_5 \kappa(t)) \cap \mathcal{C}(3C_1 t)} \mu_A t^{-K-2d-1} \leq K_4 t^{-K-d-1} \] (3.45)

for some constant \( K_4 = K_4(\mu_A, d) \).

Now consider an auxiliary process which starts at time 0 with \( N_A(w, 0-) \) particles only at the vertices \( w \in S(u, -C_5 \kappa(t)) \cap \mathcal{C}(3C_1 t) \), and with no particles outside this set. Let \( w_0 \) be the nearest vertex in \( S(u, -C_5 \kappa(t)) \) to the origin with \( N_A(w_0, 0-) > 0 \). Take the type of all particles not at \( w_0 \) equal to \( A \) and the type of the particles at \( w_0 \) equal to \( B \). If \( w_0 \) lies outside \( S(u, -C_5 \kappa(t)) \cap \mathcal{C}(3C_1 t) \), then this auxiliary process has never any \( B \)-particles. On the other hand, if \( w_0 \in S(u, -C_5 \kappa(t)) \cap \mathcal{C}(3C_1 t) \), then the auxiliary process is obtained from \( \mathcal{P}^h(u, -C_5 \kappa(t)) \) by removing at time 0 all particles in \( S(u, -C_5 \kappa(t)) \setminus \mathcal{C}(3C_1 t) \). Finally, let
\[ A_4(t) = \{ x : \text{there is a } B \text{-particle at } x \text{ at time } t \text{ in this auxiliary system} \}. \]

From our considerations above (in particular (3.42), (3.45)) we have that
\[ P\{A_2(s, t, v) \text{ intersects } \Lambda\} \geq P\{\bar{v} + A_4(t) \text{ intersects } \Lambda\} - K_4 t^{-K-d-1}. \] (3.46)

Indeed, were it not for the fact that \( N_A(w, 0-) \) is a Poisson variable of mean \( \mu_A \) instead of \( \nu(v, w, s, t) \), the auxiliary system would be obtained from the system in which \( A_2(s, t, v) \) is computed by translation by \( (-\pi, -s - C_6 \kappa(t)) \) and by removing the particles outside \( S(u, -C_5 \kappa(t)) \cap \mathcal{C}(3C_1 t) \). The term \(-K_4 t^{-K-d-1}\) corrects for increasing the mean from \( \nu(v, w, s, t) \) to \( \mu_A \).
To come to (3.40) we still want to prove the inequality

$$P\{v + A_4(t) \text{ intersects } \Lambda\} \geq P\{v + A_3(t) \text{ intersects } \Lambda\} - K_5 t^{-K-d-1}. \tag{3.47}$$

This follows from the fact that if, in $P^h(u, -C_5 \kappa(t))$ all $B$-particles stay inside $C(2C_1 t)$ during $[0, t]$, and no particle which starts outside $C(3C_1 t)$ at time 0 enters $C(2C_1 t)$ during $[0, t]$, then the particles which start outside $C(3C_1 t)$ do not interact with any particle, and do not cause the creation of any $B$-particles during $[0, t]$ (compare the argument for (2.36) in [KSb]). In these circumstances $P^h(u, -C_5 \kappa(t))$ has no more $B$-particles at time $t$ than the auxiliary process, which is obtained by removing the particles which start outside $C(3C_1 t)$ at time 0, as described above. Therefore

$$P\{v + A_4(t) \text{ intersects } \Lambda\} - P\{v + A_3(t) \text{ intersects } \Lambda\} \leq P\{w_0 \notin S(u, -C_5 \kappa(t)) \cap C(3C_1 t)\} + P\{\text{some } B\text{-particles in } P^h(u, -C_5 \kappa(t)) \text{ leave } C(2C_1 t) \text{ during } [0, t]\} + P\{\text{in } P^h(u, -C_5 \kappa(t)) \text{ some particles which start outside } C(3C_1 t) \text{ enter } C(2C_1 t) \text{ during } [0, t]\}. \tag{3.48}$$

The first term in the right hand side here is trivially $o(t^{-K-d-1})$ (compare (3.26)).

To estimate the second term in the right hand side of (3.48) we first observe that if $x_0$, the nearest occupied point to the origin at time 0, lies in the half-space $S(u, -C_5 \kappa(t))$, then at all times the $B$-particles in $P^h(u, -C_5 \kappa(t))$ are also $B$-particles in $P^f$ (see (3.3)). Therefore a decomposition with respect to the value of $x_0$ and an application of (3.7) show that the second term in the right hand side of (3.48) is (for $t \geq$ some $t_2$) bounded by

$$P\{\|x_0\| \geq K_4 \log t\} + \sum_{\|x\| \leq K_4 \log t} \mu_A P_{\text{part}}\{\text{there are } B\text{-particles outside } C(C_1 t) \text{ during } [0, t]\} \leq K_6 t^{-K-d-1} \tag{3.49}$$

(see (3.3), (3.26) and the estimates for (3.25)).

The third term in the right hand side of (3.48) is at most

$$\sum_{w \notin C(3C_1 t)} E\{N_A(w, 0-)\} P\{\sup_{r \leq t} \|S_r\| \geq \|w\| - 2C_1 t\} \leq \sum_{w \notin C(3C_1 t)} 8d \mu_A \exp[-K_7 \|w\|] \leq K_8 t^{d-1} \exp[-K_9 C_1 t] \tag{3.50}$$

(see (2.42) in [KSa]). Thus (3.47) and (3.40) hold.
Step 2. We wish to prove the following precise version of (3.35): for \( t \geq s \geq s_0, t \log t \leq C_7 s^2 \) and for some constant \( K_{10} \), independent of \( s, t, u \),

\[
P\{A_1(s, t) \text{ intersects } \Lambda \} \geq P\{ (\ell^*(s, u) + A_3(t)) \text{ intersects } \Lambda \} - K_{10} t^{-K-1}.
\]

To this end we define the following events for any vector in \( v \in \mathbb{Z}^d \):

\[
I_1(v) := \left\{ \text{during } [0, s] \text{ in the process } P^h(u, -C_5 \kappa(s)) \text{ all the } B\text{-particles stay in the set } C(2C_1 s) \cap \{ x : \langle x, u \rangle < \langle v, u \rangle + C_5 \kappa(t) \} \right\}.
\]

\[
I_2(v) := \left\{ \text{none of the particles which were at time } 0 \text{ in the half-space } S(u, \langle v, u \rangle + 2C_5 \kappa(t)) = \left\{ x : \langle x, u \rangle \geq \langle v, u \rangle + 2C_5 \kappa(t) \right\} \text{ enters the set } C(2C_1 s) \cap \left\{ x : \langle x, u \rangle < \langle v, u \rangle + C_5 \kappa(t) \right\} \text{ during } [0, s] \right\}.
\]

The following independence property is crucial for our argument: Let \( J(v) \) be an event which depends only on \( v \in \mathbb{Z}^d \) and the particles which start in \( S(u, \langle v, u \rangle + 2C_5 \kappa(t)) \) at time 0, and the paths of these particles. Then

\[
P\{ \ell^*(s, u) = v, I_1(v), I_2(v), J(v) \} = P\{ \ell^*(s, u) = v, I_1(v), I_2(v) \} P\{ J(v) | I_2(v) \}. \tag{3.52}
\]

The important feature here is that in the last conditional probability \( v \) is a constant, without relation to \( \ell^*(s, u) \). To see (3.52) we note that on the event \( I_1 \cap I_2 \) none of the particles which start in \( S(u, \langle v, u \rangle + 2C_5 \kappa(t)) \) coincides with any \( B\)-particle during \([0, s] \). Therefore, changing the paths of any of the particles which start in \( S(u, \langle v, u \rangle + 2C_5 \kappa(t)) \) has no influence on the types of any of the other particles during \([0, s] \) (and of course no influence on the paths of these other particles), as long as we stay on \( I_1 \cap I_2 \) (compare the argument for (2.36) in [KSb]). In particular,

\[
P\{ \ell^*(s, u) = v, I_1(v) | I_2(v), J(v) \} = P\{ \ell^*(s, u) = v, I_1(v) | I_2(v) \}.
\]

This is clearly equivalent to (3.52).

We take

\[
J(v) = \{ A_2(s, t, v) \text{ intersects } \Lambda \},
\]

where \( \Lambda \) is some non-random set in \( \mathbb{Z}^d \). By definition, \( A_2(s, t, v) \) depends only on \( v \) and the particles which start in the half-space \( S(u, \langle v, u \rangle + 2C_5 \kappa(t)) \). Thus also \( J(v) \) depends only on \( v \) and this last collection of particles and their paths. (This is true despite the fact that we talk about \( B\)-particles in the definition (3.33).
Indeed, these are $B$-particles in $(u, \langle v, u \rangle + 2C_5\kappa(t))$ half-space process, started at $(\overline{v}, s + C_6\kappa(t))$, and the types of these particles are reset at time $s + C_6\kappa(t)$ and after that do not depend on particles which started outside $S(u, \langle v, u \rangle + 2C_5\kappa(t))$. With this choice of $J$ we obtain from (3.52) for every fixed $v$

\[
P\{\ell^*(s, u) = v, \mathcal{I}_1(v), \mathcal{I}_2(v), A_2(s, t, v) \text{ intersects } \Lambda\} \\
\geq P\{\ell^*(s, u) = v, \mathcal{I}_1(v), \mathcal{I}_2(v)\} [P\{A_2(s, t, v) \text{ intersects } \Lambda\} - P\{\mathcal{I}_2^c(v)\}]^+.
\]  

(3.53)

We shall show in step 3 that for suitable choice of constants $0 < K_i = K_i(K, d) < \infty$, independent of $s, u$ and $v$, it is the case that for the process $P^h(u, -C_5\kappa(s))$

\[
P\{\ell^*(s, u) \in \mathcal{C}(2C_1 s), \mathcal{I}^c_1(\ell^*(s, u))\} \leq K_{11} s^{-K-1},
\]  

(3.54)

\[
P\{\mathcal{I}^c_2(v)\} \leq K_{11} s^{-K-d-1},
\]  

(3.55)

and

\[
P\{(3.36) \text{ (with } y = \ell^*(s, u)\) fails or (3.37) fails} \leq K_{11} s^{-K-1}.
\]  

(3.56)

In the remainder of this step we only show how to complete the proof of (3.51) and the proposition from the estimates (3.54)-(3.56). To this end we apply (3.53). By using (3.53), (3.55) and (3.40) we get

\[
P\{\ell^*(s, u) = v, A_2(s, t, \ell^*(s, u)) \text{ intersects } \Lambda\} \\
\geq P\{\ell^*(s, u) = v, \mathcal{I}_1(v), \mathcal{I}_2(v), A_2(s, t, v) \text{ intersects } \Lambda\} \\
\geq \left[ P\{\ell^*(s, u) = v\} - P\{\ell^*(s, u) = v, \mathcal{I}^c_1(v)\} - P\{\ell^*(s, u) = v, \mathcal{I}^c_2(v)\} \right] \\
\quad \times \left[ P\{A_2(s, t, v) \text{ intersects } \Lambda\} - P\{\mathcal{I}^c_2(v)\} \right]^+ \\
\geq P\{\ell^*(s, u) = v\} P\{A_2(s, t, v) \text{ intersects } \Lambda\} \\
\quad - P\{\ell^*(s, u) = v, \mathcal{I}^c_1(v)\} - 2K_{11} s^{-K-d-1} \\
\geq P\{\ell^*(s, u) = v\} P\{\overline{\nu} + A_3(t) \text{ intersects } \Lambda\} \\
\quad - P\{\ell^*(s, u) = v, \mathcal{I}^c_1(v)\} - (2K_{11} + K_4 + K_5) s^{-K-d-1}.
\]  

(3.57)

Now recall that $A_1(s, t) \supset A_2(s, t, \ell^*(s, u))$ on the intersection of (3.36) and (3.37). Summing (3.57) over all $v \in \mathcal{C}(2C_1 s)$, and using (3.54) and (3.56), therefore gives

\[
P\{A_1(s, t) \text{ intersects } \Lambda \text{ and (3.36), (3.37) occur}\} \\
\geq P\{A_2(s, t, \ell^*(s, u)) \text{ intersects } \Lambda\} - P\{\text{(3.36) or (3.37) fails}\} \\
\geq \sum_{v \in \mathcal{C}(2C_1 s)} P\{\ell^*(s, u) = v\} P\{\overline{\nu} + A_3(t) \text{ intersects } \Lambda\} - K_{12} s^{-K-1}.
\]  

(3.58)
Finally, since \( \ell^*(s, u) \) is the location of a \( B \)-particle at time \( s \) in \( \mathcal{P}^h(u, -C_5 \kappa(s)) \), we have, essentially as in the estimate for \( \mathcal{P}^h \{ \mathcal{E}_{k,4} \} \) in (3.25) and the lines following it, or the estimate of the second term in the right hand side of (3.48)

\[
P \{ \ell^*(s, u) \notin \mathcal{C}(2C_1 s) \} \leq P \{ \|x_0\| > C_1 s \wedge C_5 \kappa(s)/\sqrt{d} \} + \sum_{\|x\| \leq C_1 s} \mu_A P^\alpha \{ \text{there is a } B\text{-particle outside } \mathcal{C}(C_1 s) \text{ at time } s \} \leq K_{13} s^{-K-1}.
\]

(3.59)

Consequently

\[
P \{ A_1(s, t) \text{ intersects } \Lambda \} \geq \sum_{v \in \mathbb{Z}^d} P \{ \ell^*(s, u) = v \} P \{ \tau + A_3(t) \text{ intersects } \Lambda \} - (K_{12} + K_{13}) s^{-K-1}.
\]

(3.60)

This is the desired (3.51).

(3.31) is just the special case of (3.60) with \( \Lambda = \Gamma(\alpha, \beta, \gamma_s + \gamma_t) \). Indeed, \( \{ A_1(s, t) \text{ intersects } \Lambda \} \) is the event that there is a \( B \)-particle in \( \Lambda \) at time \( s + t + C_5 \kappa(t) \) in the process \( \mathcal{P}^h(u, -C_5 \kappa(s + t + C_6 \kappa(t))) \). For \( \Lambda = \Gamma(\alpha, \beta, \gamma_s + \gamma_t) \) this event is also denoted by \( \mathcal{G}(\alpha, \beta, \gamma_s + \gamma_t) \), \( \mathcal{P}^h(u, -C_5 \kappa(s + t + C_6 \kappa(t))) \), \( s + t + C_6 \kappa(t) \).

Thus, the left hand sides of (3.31) and (3.60) are the same for this choice of \( \Lambda \). We leave it to the reader to check that the right hand side of (3.60) is at least as large as the right hand side of (3.31), provided we choose \( C_8 \geq K_{12} + K_{13} \).

Step 3. Here we prove the relations (3.54)-(3.56). Note that (3.56) also supplies the missing estimates for (3.34), to wit, \( P \{ \text{(3.36) and (3.37 hold)} \} \geq 1 - s^{-K-1} \).

Now we start on (3.54). First

\[
P \{ \text{in } \mathcal{P}^h(u, -C_5 \kappa(s)) \text{ some } B\text{-particle leaves } \mathcal{C}(2C_1 s) \text{ during } [0, s] \} = O(s^{-K-d-1})
\]

(3.61)

(see (3.49)). In addition, by definition of \( l^*(s, u) \), \( \langle l^*(s, u), u \rangle = h(s, u, -C_5 \kappa(s)) \).

Thus

\[
P \{ \text{in } \mathcal{P}^h(u, -C_5 \kappa(s)) \text{, during } [0, s] \text{ all } B\text{-particles stay in } \mathcal{C}(2C_1 s), \text{ but some of them leave } \{ x : \langle x, u \rangle < \langle \ell^*(s, u), u \rangle + C_5 \kappa(s) \} \}
\]

\[
\leq P \{ \text{in } \mathcal{P}^h(u, -C_5 \kappa(s)), \text{ at some time } r \leq s \text{ there are } B\text{-particles at some } v \in \mathcal{C}(2C_1 s) \text{ with } \langle v, u \rangle \geq \max \{ \langle x, u \rangle : \text{ there is a } B\text{-particle at } x \text{ at time } s \} + C_5 \kappa(s) \}.
\]

(3.62)

This last event can happen only if some \( B\)-particle reaches a vertex \( v \in \mathcal{C}(2C_1 s) \) before time \( s \) and then this particle moves to some \( x \) at time \( s \) with \( \langle x, u \rangle < \langle v, u \rangle - C_5 \kappa(s) \). The probability that such particle started outside \( \mathcal{C}(3C_1 s) \) is bounded by
the third term in the right hand side of (3.48), with \( t \) replaced by \( s \). Therefore, the right hand side of (3.62) is at most

\[
\text{(third term in right hand side of (3.48) with } t \text{ replaced by } s) + \sum_{w \in C(3C_1s)} E\{N_A(w, 0-) P\{ \sup_{0 \leq r_1, r_2 \leq s} \|S_{r_1} - S_{r_2}\| \geq C_5 \kappa(s)/\sqrt{d} \} \leq K_8 s^{d-1} \exp[-K_9 C_1 s] + K_{14} (3C_1 s)^d \exp[-K_{15} C_5^2 \log s],
\]

\[(3.63)\]

by (3.50) and by (2.42) in [KSa]. Together with (3.61) this proves that we can take \( C_5 \) so large that (3.54) holds. As observed after (3.44) we can even choose \( C_5 \) so that (3.44) is also valid. Once we have chosen \( C_5 \) we fix

\[ C_6 = \frac{16C_5}{C_2}. \]

\[(3.64)\]

As for (3.55), we have

\[
P\{T_2^e(v) \leq \sum_{w \in S(u, (v, u) + 2C_5 \kappa(s))} E\{N_A(w, 0-) \times P\{ \sup_{r \leq s} \|S_r\| \geq C_5 \kappa(t) \lor (\|w\| - 2C_1 s) \}\}. \]

\[(3.65)\]

We leave it to the reader to show that this is \( O(s^{-K-d-1}) \) for \( t \geq s \) and large enough \( C_5 \) (again by (2.42) in [KSa]).

Finally, to prove (3.56), we note first that \( P\{(3.37) \text{ fails} \} = O(s^{-K-1}) \), provided \( K_3 = K_3(\mu_A, d) \) is taken large enough, just as in (3.26). Next,

\[
P\{\{\ell^*(s, u), u < 0\} \leq P\{h(s, u, -C_5 \kappa(s)) \leq C_4 s\} \leq [C_5 \kappa(s)]^{-2K-2} \leq s^{-K-1}
\]

\[(3.66)\]

for large \( s \), by virtue of Lemma 2 with \( K \) replaced by \( 2K + 2 \). Lastly, we have to show that for the choice of \( C_6 \) in (3.64)

\[
P\{z(s, t) \text{ is not occupied by a } B\text{-particle in } P^h(u, -C_5 \kappa(s)) \text{ at time } s + C_6 \kappa(t)\}
\leq P\{z(s, t) \text{ is not occupied by a } B\text{-particle in } P^h(u, -C_5 \kappa(s)) \text{ at time } s + C_6 \kappa(t) \text{, but } z(s, t) \in \ell^*(s, u) + C(2C_6 \kappa(t)/2) \}
+ P\{z(s, t) \notin \ell^*(s, u) + C(2C_6 \kappa(t)/2) \}
= O(s^{-K-1}).
\]

\[(3.67)\]

The first inequality here is obvious. The bound \( O(s^{-K-1}) \) for the middle member of (3.67) is formulated as a separate lemma, because the same argument will be needed once more in the next section. To see that (3.67) follows from Lemma 4 below, recall that \( z(s, t) \) is occupied at time \( s + C_6 \kappa(t) \) by some particle which started at time
Lemma 4. Let \( y \) all occupied sites “near” next lemma. This proves the bound \( O \) and all \( v \) given in (3.41). By the estimate (3.43) we have \( \text{in} \ S \) However, the numbers of particles at sites \( \ell \) to the possible values of \( \ell \) at time \( s + C_6 \kappa(t) \). Also, \( \ell^*(s, u) \) is occupied by at least one \( B \)-particle in \( \mathcal{P}^h(u, -C_5 \kappa(s)) \) at time \( s \). So Lemma 4 with \( \tilde{s} = s + C_6 \kappa(t) \) and \( y(s) = \ell^*(s, u) \) (and \( C_6 \) as in (3.64)) shows that the middle member of (3.67) is at most

\[
P\{\ell^*(s, u) \not\in C(2C_1 s)\} + P\{\langle \ell^*(s, u), u \rangle \leq C_4 s/2\} + s^{-K-1}
\]

\[
+ P\{z(s, t) \not\in \ell^*(s, u) + C(C_2C_6 \kappa(t)/2)\}. 
\]

Note that we used the second part of condition (3.30) here; we have to choose \( C_7 \) small enough to make sure that (3.72) holds for \( \tilde{s} - s = C_6 \kappa(t) \). The first two terms in (3.68) are \( O(s^{-K-1}) \), by virtue of (3.61) and (3.66). The fourth term is bounded by

\[
P\{z(s, t) \not\in \ell^*(s, u) + C(C_2C_6 \kappa(t)/2)\} \leq P\{\|z(s, t) - \ell^*(s, u)\| > 4C_5 \kappa(t) - 1\}
\]

(because \( C_2C_6/2 = 8C_5 \) and \( \|\ell^*(s, u) - \ell^*(s, u)\| \leq 4C_5 \kappa(t) + 1 \))

\[
\leq P\{\ell^*(s, u) \not\in C(2C_1 s)\} + P\{\ell^*(s, u) \in C(2C_1 s)\}, \text{ and none of the sites}
\]

in \( \ell^*(s, u) + C(4C_5 \kappa(t) - 1) \) are occupied at time \( s + C_6 \kappa(t) \) by a particle which started in \( S(u, \langle \ell^*(s, u), u \rangle + 2C_5 \kappa(t)) \} \}

We already saw in (3.59) that the first term in the right hand side is \( O(s^{-K-1}) \). As for the second term in the right hand side, this is by a decomposition with respect to the possible values of \( \ell^*(s, u) \), analogously to (3.9), at most

\[
K_{16} \sum_{v \in C(2C_1 s)} P\{\text{none of the sites in } \sigma + C(4C_5 \kappa(t) - 1) \text{ is occupied at time}
\]

\[
s + C_6 \kappa(t) \text{ by a particle which started in } S(u, \langle v, u \rangle + 2C_5 \kappa(t)) \} \}
\]

(3.70)

However, the numbers of particles at sites \( \sigma + w \) at time \( s + C_6 \kappa(t) \) which started in \( S(u, \langle v, u \rangle + 2C_5 \kappa(t)) \) are independent Poisson variables with means \( \nu(v, w, s, t) \) given in (3.41). By the estimate (3.43) we have \( \nu(v, w, s, t) \geq \mu_A/2 \) for \( \langle w, u \rangle \geq 0 \) and all \( v \) (and \( t \) large enough). Therefore (3.70) is at most \( K_1 \sum_{v \in C(2C_1 s)} \exp[-K_{18} \kappa^d(t) \mu_A] \). This proves the bound \( O(s^{-K-1}) \) in (3.67), and therefore (3.56) is reduced to the next lemma.

Roughly speaking, the next lemma guarantees that if a certain vertex \( y(s) \) has a \( B \)-particle in the half-space process \( \mathcal{P}^h(u, -C_5 \kappa(s)) \) at a time \( s \), then a little later all occupied sites “near” \( y(s) \) will actually have a \( B \)-particle in \( \mathcal{P}^h(u, -C_5 \kappa(s)) \).

**Lemma 4.** Let \( s, \tilde{s} \) and \( t \) be such that

\[
s \leq t
\]

(3.71)
and
\[
\frac{16C_5}{C_2}\kappa(t) \leq \tilde{s} - s \leq \frac{C_4}{8C_1}s. \tag{3.72}
\]

Let \( u \in S^{d-1} \) be fixed and let \( y(s) \in \mathbb{Z}^d \) be a random point (that is, \( y(s) \) may depend on the sample point \( \sigma \)). Define the event \( \mathcal{K}(y) \) by

\[
\mathcal{K}(y) := \{ \text{there exists a site } z \in y + \mathcal{C}(C_2(\tilde{s} - s)/2) \text{ such that at time } \tilde{s}, \ z \text{ is occupied in } \mathcal{P}^f, \text{ but is not occupied by a } B\text{-particle in } \mathcal{P}^h(u, -C_5\kappa(s)) \}. \tag{3.73}
\]

Then for each \( K > 0 \) there exists an \( s_1 = s_1(K) \) (independent of \( u \)) such that

\[
P\{B^h(y(s), s; u, -C_5\kappa(s)) \cap \mathcal{K}(y(s))\}
\]
\[
\leq P\{y(s) \notin \mathcal{C}(2C_1s)\} + P\{\langle y(s), u \rangle < \frac{1}{2}C_4s\} + s^{-K-1} \tag{3.74}
\]

for \( s \geq s_1 \) (see (3.13) for \( B^h \)).

**Proof.** Assume that the space-time point \((y, s)\) is occupied by some particle in \( \mathcal{P}^h(u, -C_5\kappa(s)) \). We can then define the following auxiliary events:

\( \mathcal{K}_1(y) := \{ \text{there exists a site } z \in y + \mathcal{C}(C_2(\tilde{s} - s)/2) \text{ such that } (z, \tilde{s}) \text{ is occupied in } \mathcal{P}^f, \text{ but is not occupied in } \mathcal{P}^h(u, -C_5\kappa(s)) \} \),

\( \mathcal{K}_2(y) := \{ \text{there exists a site } z \in y + \mathcal{C}(C_2(\tilde{s} - s)/2) \text{ such that } (z, \tilde{s}) \text{ is occupied by an } A\text{-particle in the full-space process starting at } (y, s) \} \),

\( \mathcal{K}_3(y) := \{ \text{there exists a site } z \in y + \mathcal{C}(C_2(\tilde{s} - s)/2) \text{ such that } (z, \tilde{s}) \text{ is occupied by a } B\text{-particle in the full-space process starting at } (y, s), \text{ but occupied by an } A\text{-particle in the } (u, -C_5\kappa(s)) \text{ half-space process starting at } (y, s) \} \),

\( \mathcal{K}_4(y) := \{ \text{in the full-space process starting at } (y, s) \text{ some } B\text{-particles leave } y + \mathcal{C}(2C_1(\tilde{s} - s)) \text{ during } [s, \tilde{s}] \} \),

\( \mathcal{K}_5(y) := \{ \text{some particles which start outside } S(u, -C_5\kappa(s)) \text{ at time } 0, \text{ enter } y + \mathcal{C}(2C_1(\tilde{s} - s)) \text{ during } [s, \tilde{s}] \} \).

We shall first show that

\[
B^h(y, s; u, -C_5\kappa(s)) \cap \mathcal{K}(y) \subset \bigcup_{i=1}^{3} \mathcal{K}_i(y) \text{ and } \mathcal{K}_3(y) \subset \mathcal{K}_4(y) \cup \mathcal{K}_5(y). \tag{3.75}
\]

and then estimate \( P\{y(s) \in \mathcal{C}(2C_1s), \langle y(s), u \rangle \geq C_4s/2, \mathcal{K}_i(y(s))\} \) for \( 1 \leq i \leq 5 \). To prove the first part of (3.75), consider a sample point for which \( B^h(y, s; u, -C_5\kappa(s)) \cap \mathcal{K}(y) \subset \bigcup_{i=1}^{3} \mathcal{K}_i(y) \).
$K(y)$ occurs and let $z$ be a site in $y + C(\langle C_2(s - s)/2 \rangle)$ such that $(z, s)$ is occupied in $P^f$, but is not occupied by a $B$-particle in $P^h(u, -C_5\kappa(s))$. Then it may be that $(z, s)$ is not occupied at all in $P^h(u, -C_5\kappa(s))$. This would mean that $K_1(y)$ occurs. If this fails, then $(z, s)$ is occupied in $P^h(u, -C_5\kappa(s))$, necessarily by an $A$-particle. We claim that $(z, s)$ is then also occupied by an $A$-particle in the $(u, -C_5\kappa(s))$ half-space process starting at $(y, s)$. This is so, because starting at $(y, s)$ does not remove any particles, but it may change some types. But on $B^h(y, s; u, -C_5\kappa(s))$, $y$ has already at least one $B$-particle at time $s$ in $P^h(u, -C_5\kappa(s))$. Thus the resetting at time $s$ only changes some types from $B$ to $A$, and since $z$ already has type $A$ at time $s$ in $P^h(u, -C_5\kappa(s))$, it will (by Lemma C) also have type $A$ at time $s$ in the $(u, -C_5\kappa(s))$ half-space process started at $(y, s)$, as claimed. $(z, s)$ is also occupied in the full-space process starting at $(y, s)$ (since it is occupied in the full-space process, starting at $(0, 0)$). The type at $(z, s)$ in this process may be $A$, in which case $K_2(y)$ occurs, or $B$, in which case $K_3(y)$ occurs. This proves the first inclusion in (3.75).

The second part of (3.75) follows from the argument given for (3.47). $K_3(y)$ requires that there are particles in $y + C(\langle C_2(s - s)/2 \rangle)$ which have different types at time $\tilde{s}$ in the full-space and in the $(u, -C_5\kappa(s))$ half-space process, both starting at $(y, s)$. This means that in the full-space process starting at $(y, s)$ the type of some particle which is in $y + C(\langle C_2(s - s)/2 \rangle)$ at time $\tilde{s}$ is influenced by particles which started outside $S(u, -C_5\kappa(s))$ at time 0. However, this can happen only if in the full-space process starting at $(y, s)$, these particles meet some $B$-particles during $[s, \tilde{s}]$. In turn, this can happen only if $K_4(y)$ or $K_5(y)$ occurs. This proves the second inclusion in (3.75).

Our next task is to find bounds for

$$P\{y(s) \in C(2C_1s), \langle y(s), u \rangle \geq C_4s/2, B^h(y(s), s; u, -C_5\kappa(s)), K_i(y(s))\}, i = 1, 2, 4, 5.$$  

For $i = 1$ we have

$$P\{y(s) \in C(2C_1s), \langle y(s), u \rangle \geq C_4s/2, K_1(y(s))\} \leq \sum_{w \not\in S(u, -C_5\kappa(s))} \sum_{\langle z, u \rangle \geq C_4s/2 - C_2(s - s)/2} E\mathcal{N}_A(w, 0-)P\{w + S_{\tilde{s}} = z\}$$  

$$\leq \sum_{w \in C(4C_1s)} \mu_A \{\|S_{\tilde{s}}\| \geq C_4s/(4\sqrt{d})\} + \sum_{w \not\in C(4C_1s)} \mu_A \{\|S_{\tilde{s}}\| \geq \|w\|/2\}$$  

$$\leq s^{-K-1}$$  

(3.76)

for all $s \geq s_1 = s_1(K)$. In the first inequality we used that $\|z\| \leq \|z - y(s)\| + \|y(s)\| \leq C_2(s - s)/2 + 2C_1s \leq (2C_1 + C_4)s$, by virtue of (3.72) and the inequality $C_2 \leq C_1$. In the second inequality we used that for the summands here we have $\|w - z\| \geq ((z - w), u)/\sqrt{d} \geq [C_4s/2 - C_2(s - s)/2 + C_5\kappa(t)]/\sqrt{d} \geq C_4s/(4\sqrt{d}).$

For the third inequality we use $\tilde{s} \leq (1 + C_4/(8C_1))s$ plus (2.42) in [KSa]; compare (3.24).
Next, we remind the reader that $P^{\text{or}}$ is the probability measure governing the original model, in which one $B$-particle is added at the origin at time 0. In this notation we have, by (3.9) and (2.4),

$$P\{y(s) \in C(2C_1s), B^h(y(s), s; u, -C_5\kappa(s)), K_2(y(s))\}$$

$$\leq K_{19}s^dP^{\text{or}}\{\text{there exists a } z \in C(C_2(\tilde{s} - s)/2) \text{ which is occupied by an } A\text{-particle at time } \tilde{s} - s\}$$

$$\leq 2s^{-K-1}. \quad (3.77)$$

Again by (3.9)

$$P\{y(s) \in C(2C_1s), K_4(y(s))\}$$

$$\leq K_{19}s^dP^{\text{or}}\{\text{some } B\text{-particles leave } C(2C_1(\tilde{s} - s)) \text{ during } [0, \tilde{s} - s]\}$$

$$\leq s^{-K-1} \quad \text{(by (3.49))}. \quad (3.78)$$

Finally,

$$P\{y(s) \in C(2C_1s), \langle y(s), u \rangle \geq C_4s/2, K_5(y(s))\}$$

$$\leq \sum_{w: \langle w, u \rangle < -C_5\kappa(s)} \sum_{v \in C((2C_1+C_4)s)} EN_A(w, 0)P\{w + S_r = v \text{ for some } r \leq \tilde{s}\}$$

$$\leq \mu_A \sum_{w \in C((4C_1+2C_4)s)} P\{\sup_{r \leq (1+C_4/(8C_1))s} \|S_r\| \geq C_4s/(4\sqrt{d})\}$$

$$+ \mu_A \sum_{w \notin C((4C_1+2C_4)s)} P\{\sup_{r \leq (1+C_4/(8C_1))s} \|S_r\| \geq \|w/2\|\}$$

$$\leq s^{-K-1} \quad \text{(compare (3.76))}. \quad (3.79)$$

Together with (3.75) these estimates prove (3.74). ■

**Corollary 5.** For every unit vector $u$ there exists a constant $\lambda(u) \in [C_4, 2\sqrt{d}C_1]$ such that

$$\lim_{t \to \infty} \frac{1}{t}h^*(t, u) = \lambda(u) \text{ almost surely and in } L^p \text{ for all } p > 0. \quad (3.80)$$

$t$ runs through the reals here. Moreover, for each $\eta > 0$ there exist an exponentially increasing sequence $\{n_1 < n_2 < \ldots\} = \{n_1(\eta) < n_2(\eta) < \ldots\}$ (independent of $u$) such that

$$1 < \frac{n_{j+1}}{n_j} \leq 1 + \eta, \quad j \geq 1,$$

and such that every $\varepsilon > 0$,

$$\sum_{k=0}^{\infty} P\left\{\left| \frac{1}{n_k}h^*(n_k, u) - \lambda(u) \right| > \varepsilon \right\} < \infty. \quad (3.81)$$
Finally, for given \( \eta > 0 \) and \( \eta' \leq \eta \) and \( \{n_j(\eta)\} \) corresponding to \( \eta \), we can choose the \( n_j(\eta') \) such that for some \( j_0 < \infty \), \( \{n_j(\eta')\} \supset \{n_j(\eta) : j \geq j_0\} \).

**Proof.** The basis for this proof is (3.31) with \( \beta = \infty \). Since \( \Gamma(\alpha, \infty, \gamma, u) = \{x \in \mathbb{R}^d : \langle x, u \rangle \geq \alpha\} = S(u, \alpha) \), we have

\[
\mathcal{G}(\alpha, \infty, \gamma, \mathcal{P}, t) = \{\text{in } \mathcal{P}, \text{ at time } t, \text{ there is a } B\text{-particle at some } x \text{ with } \langle x, u \rangle \geq \alpha\}.
\]

In particular

\[
\mathcal{G}(\alpha, \infty, \gamma, \mathcal{P}^h(u, -C_5 \kappa(s + t + C_6 \kappa(t)), s + t + C_6 \kappa(t)) = \{h(s + t + C_6 \kappa(t), u, -C_5 \kappa(s + t + C_6 \kappa(t))) \geq \alpha\}
\]

\[
= \{h^*(s + t + C_6 \kappa(t), u) \geq \alpha\}.
\]

Similarly,

\[
\mathcal{G}(\alpha, \infty, \gamma, \mathcal{P}^h(u, -C_5 \kappa(t)), t) = \{h^*(t, u) \geq \alpha\}.
\]

Thus, (3.31) with \( \beta = \infty \) says that, under (3.30),

\[
P\{h^*(s + t + C_6 \kappa(t), u) \geq \alpha\} \geq P\{h_1^*(s, u) + h_2^*(t, u) \geq \alpha\} - C_8 s^{-K-1}, \quad (3.82)
\]

where \( h_1^*(s, u) \) and \( h_2^*(t, u) \), are independent copies of \( h^*(s, u) \) and \( h^*(t, u) \), respectively.

The corollary will be derived from this relation by more or less standard subadditivity techniques. To apply these techniques we first derive some simple properties of \( h^*(s, u) \). The first is the following tail estimate:

\[
P\{h^*(s, u) \geq \alpha\} + P\{\|m^*(s, u)\| \geq \alpha\} \leq \exp[-K_1 \alpha] \text{ for } \alpha \geq 2 \sqrt{d} C_1 s, \quad s \geq s_3, \quad (3.83)
\]

where \( s_3 = s_3(K) \) is some constant independent of \( \alpha, u \). The second and third property are semi-continuity properties in \( s \), namely

\[
P\{\inf_{r \leq t} h^*(s + r, u) - h^*(s, u) \leq -\alpha\}
\]

\[
\leq K_3 s^{-K} + P\{\|\sup_{r \leq t} S_r\| \geq \alpha\} \leq K_3 s^{-K} + 8d \exp \left[-\frac{K_2 \alpha^2}{t + \alpha}\right], \quad \alpha \geq 0, \quad (3.84)
\]

and

\[
P\{\sup_{r \leq t} h^*(s + r, u) - h^*(s + t, u) \geq \alpha\}
\]

\[
\leq K_3 s^{-K} + K_4(s + t)^d \exp \left[-\frac{K_2 \alpha^2}{t + \alpha}\right], \quad \alpha \geq 0. \quad (3.85)
\]
To prove (3.83) take \( \alpha \geq 2\sqrt{d}C_1s \). Since \( \langle x, u \rangle \leq \|x\|_2 \leq \sqrt{d}\|x\| \), as well as \( \|x^+\| \leq \|x\|_2 \leq \sqrt{d}\|x\| \), the left hand side of (3.83) is then bounded by

\[
2P\{\text{in } P^h(u, -C_5\kappa(s)) \text{ there is a } B\text{-particle outside } C(\alpha/\sqrt{d}) \text{ at some time during } [0, s] \subset [0, [2\sqrt{d}C_1]^{-1}\alpha]\} \leq 2P\{\text{nearest site } x \text{ to } 0 \text{ in } S(u, -C_5\kappa(s)) \text{ with } N_A(x, 0-) > 0 \text{ lies outside } C(\alpha/(2\sqrt{d}))\} + \sum_{x \in C(\alpha/(2\sqrt{d}))} \mu_A4E^{or}\{\text{number of } B\text{-particles outside } C(\alpha/(2\sqrt{d})) \text{ at time } [2\sqrt{d}C_1]^{-1}\alpha\},
\]

by an application of (3.7) and the argument following (3.25), very much as in (3.49). The first term in the right hand side here is at most \( 2\exp[-K_5\alpha^d] \), and the second term is at most \( K_6\alpha^d \exp[-[2\sqrt{d}C_1]^{-1}\alpha] \), by virtue of Theorem 1 in [KSb]. Thus (3.83) holds.

The argument for (3.84) is basically already given in (3.19). Moreover, it is similar to, but simpler than the proof of (3.85) so we only prove the latter. If \( h^*(s + t, u) = h \), then all \( B\)-particles in \( P^h(u, -C_5\kappa(s + t)) \) are located in \( \{x : \langle x, u \rangle \leq h\} \) at time \( s + t \). If for some \( 0 \leq r \leq t, h^*(s + r, u) \geq h + \alpha \), then there is some \( B\)-particle \( \rho \) in \( P^h(u, -C_5\kappa(s + r)) \) in \( \{x : \langle x, u \rangle \geq h + \alpha\} \) at time \( s + r \). This \( \rho \) is also a particle present in \( P^h(u, -C_5\kappa(s + t)) \) and even of type \( B \) in \( P^h(u, -C_5\kappa(s + t)) \) at time \( s + t \), provided \( \|x_0\| \leq C_5\kappa(s)/\sqrt{d} \) (see (3.3)). Thus in this case \( \rho \) moved over a distance at least \( \alpha/\sqrt{d} \) during \([s + r, s + t]\). Therefore, the left hand side of (3.85) is at most

\[
P\{\|x_0\| > C_5\kappa(s)/\sqrt{d}\} + P\{\text{some particle which starts outside } C(3C_1(s + t)) \text{ becomes a } B\text{-particle in } P^f \text{ before time } s + t\} + \sum_{x \in C(3C_1(s + t))} \mu_A4E^{or}\{\sup_{r \leq t} \|S_r - S_t\| \geq \alpha/\sqrt{d}\}
\]

\[
\leq K_7s^{-\kappa} + K_8(s + t)^d \exp[-\frac{K_9\alpha^2}{d(t + \alpha)}]
\]

(see (3.48)-(3.50), as well as (2.42) in [KSa]).

We can now proceed with subadditivity arguments. We introduce the random variables

\[
X(s) = [2\sqrt{d}C_1s - h^*(s, u)]^+
\]

and the deterministic quantities \( Y(t) = 2\sqrt{d}C_1C_6\kappa(t) \), and let \( X'(t) \) be a copy of \( X(t) \) which is independent of \( X(s) \). Then (3.82) shows that, under (3.30), these
random variables satisfy

$$P\{X(s + t + C_6\kappa(t)) \leq \beta\} \geq P\{X(s) + X'(t) + Y(t) \leq \beta\} - C_8s^{-K-1} \quad (3.86)$$

for $\beta \geq 0$. Of course this inequality also holds trivially for $\beta < 0$. This is very close to the principal hypothesis of the lemma on p. 674 of [Ha] but we have to do some extra work because of the $C_6\kappa(t)$ which appears in the argument on the left hand side of (3.86). From now on we take $K = 4$. Combining (3.86) with

$$EX^p(s + t + C_6\kappa(t)) = p \int_0^{2\sqrt{d}C_1(s + t + C_6\kappa(t))} \alpha^{p-1}P\{X(s + t + C_6\kappa(t)) \geq \alpha\}d\alpha$$

$$\leq p \int_0^{2\sqrt{d}C_1(s + C_6\kappa(t))} \alpha^{p-1}P\{X(s) + X'(t) + Y(t) \geq \alpha\}d\alpha + C_8[2\sqrt{d}C_1]^p(s + t + C_6\kappa(t))^p s^{-K-1},$$

we obtain

$$EX(s + t + C_6\kappa(t)) \leq EX(s) + EX(t) + 2\sqrt{d}C_1C_6\kappa(t) + K_{10}[s + t + C_6\kappa(t)]s^{-K-1} \quad (3.87)$$

and

$$EX^2(2s + C_6\kappa(s)) \leq E[X(s) + X'(s) + Y(s)]^2 + K_{10}[s + C_6\kappa(s)]^2 s^{-K-1}$$

$$\leq E[X(s) + X'(s) + Y(s)]^2 + 4K_{10}s^{-K+1}. \quad (3.88)$$

(3.88) holds for any $s \geq s_0$, but so far (3.87) has only been proven under (3.30). But there is a simple replacement for this inequality that holds as soon as $s_0 \leq s \leq t$. Indeed, assume that $s_0 \leq s \leq t$, but $t \log t > C_7s^2$. We first observe that then

$$X(s + t + C_6\kappa(t)) - X(t) \leq 2\sqrt{d}C_1[s + t + C_6\kappa(t)] \leq 5\sqrt{d}C_1t,$$

provided $s_0$ is large enough. Further, it follows from the simple inequality

$$[a + b - c]^+ - [a - d]^+ \leq |b| + [a - c]^+ - [a - d]^+ \leq |b| + [c - d]^+ \quad (3.89)$$

that

$$X(s + t + C_6\kappa(t)) - X(t) \leq 2\sqrt{d}C_1[s + C_6\kappa(t)] + [h^*(s + t + C_6\kappa(t), u) - h^*(t, u)]^-.$$
It follows that
\[
EX(s + t + C_6 \kappa(t)) - EX(t) \\
\leq 2\sqrt{dC_1}[s + C_6 \kappa(t)] + E\left[h^*(s + t + C_6 \kappa(t), u) - h^*(t, u)\right] - 5\sqrt{dC_1}t \\
\leq 2\sqrt{dC_1}[s + C_6 \kappa(t)] + \int_0^{5\sqrt{dC_1}t} P\{h^*(s + t + C_6 \kappa(t), u) \leq h^*(t, u) - \alpha\} d\alpha \\
\leq 2\sqrt{dC_1}[s + C_6 \kappa(t)] + 5K_3\sqrt{dC_1}tt^{-3} + 8d\int_0^\infty \exp\left[-\frac{K_2\alpha^2}{s + C_6 \kappa(t) + \alpha}\right] d\alpha
\]
(by (3.84) with \(K\) taken as 3)
\[
\leq 2\sqrt{dC_1}[s + C_6 \kappa(t)] + K_{11}[s + C_6 \kappa(t)]^{1/2} \leq K_{12}\kappa(t). \quad (3.90)
\]
Together with (3.87) this shows
\[
EX(s + t + C_6 \kappa(t)) \leq EX(s) + EX(t) + K_{13}\kappa(s + t) \quad (3.91)
\]
for all \(s_0 \leq s \leq t\).

We shall next use a small variation on the argument of [Ha] to show that (3.91) implies
\[
\lambda(u) := \lim_{t \to \infty} \frac{1}{t} Eh^*(t, u)) \text{ exists.} \quad (3.92)
\]
It suffices for (3.92) to show that
\[
\lim_{t \to \infty} \frac{1}{t} EX(t) = 2\sqrt{dC_1} - \lambda(u), \quad (3.93)
\]
because
\[
\lim_{t \to \infty} \frac{1}{t} E\{h^*(t, u); h^*(t, u) \geq 2\sqrt{dC_1}t\} = 0,
\]
by virtue of (3.83). Now define for any \(M \geq e\),
\[
t_0(M) = M, \ t_{k+1}(M) = 2t_k(M) + C_6 \kappa(t_k(M)).
\]
Note that \(t_{k+1}/t_k \geq 2\), and hence \(t_k(M) \geq 2^k M\), and for large \(k\)
\[
1 < \frac{t_{k+1}(M)}{2t_k(M)} \leq 1 + \frac{C_6}{2} \left(\frac{k \log 3}{2^k M}\right)^{1/2},
\]
and for some \(K_{14}\), independent of \(k \geq 0\),
\[
1 \leq \prod_{j=0}^{k-1} \frac{t_{j+1}(M)}{2t_j(M)} = \frac{t_k(M)}{M2^k} \leq 1 + \frac{K_{14}}{M^{1/2}}. \quad (3.94)
\]
Also, by (3.91), for all \(M \geq s_0 + e\),
\[
EX(t_k(M)) \leq 2EX(t_{k-1}(M)) + K_{13}\kappa(t_k(M)), \ k \geq 1.
\]
Consequently,
\[
\frac{EX(t_k(M))}{t_k(M)} \leq \frac{EX(M)}{M} \prod_{j=1}^{k} \frac{2t_{j-1}(M)}{t_j(M)} + K_{13} \sum_{\ell=0}^{k-1} \frac{\kappa(t_{k-\ell}(M))}{t_{k-\ell}(M)} \prod_{j=k-\ell+1}^{k} \frac{2t_{j-1}(M)}{t_j(M)}
\]
\[
\leq \frac{EX(M)}{M} + K_{15} \frac{[\log M]^{1/2}}{M^{1/2}}, \quad k \geq 0.
\]

In particular, for given \( \varepsilon > 0 \) we can choose \( M \geq s_0 + \varepsilon \) so large, that
\[
K_{15}[\log M]^{1/2}M^{-1/2} < \varepsilon \quad \text{and} \quad EX(M)/M \leq \liminf_{s \to \infty} EX(s)/s + \varepsilon.
\]

Then
\[
\frac{EX(t_k(M))}{t_k(M)} \leq \liminf_{s \to \infty} \frac{EX(s)}{s} + 2\varepsilon, \quad k \geq 0. \quad (3.95)
\]

Now let \( q_0 \geq s_0 + M \) be large. We shall expand \( q_0 \) as a sum of the form \( \sum t_{k(i)} \) plus some error terms (see (3.97)) and obtain a corresponding bound for \( EX(q_0) \) in (3.96). We define \( k(1) \) as the unique integer \( k \) for which \( t_k \leq q_0 < t_{k+1} \). We distinguish two cases. We are in the first case if \( q_0 \geq t_{k(1)} + C_6 k(t_{k(1)}) + s_0 + M \). In this case we set \( q_1 = q_0 - t_{k(1)} - C_6 k(t_{k(1)}) < t_{k(1)+1} - t_{k(1)} - C_6 k(t_{k(1)}) = t_{k(1)} \). Then \( s_0 + M \leq q_1 < t_{k(1)} \) and
\[
EX(q_0) \leq EX(t_{k(1)}) + EX(q_1) + K_{13} \kappa(q_0),
\]
by virtue of (3.91). If \( t_{k(1)} \leq q_0 < t_{k(1)} + C_6 k(t_{k(1)}) + s_0 + M \), then, as in (3.89),(3.90),
\[
EX(q_0)
\leq EX(t_{k(1)}) + 2\sqrt{dC_1} [q_0 - t_{k(1)}] + \int_0^{2\sqrt{dC_1} q_0} P\{h^*(q_0, u) - h^*(t_{k(1)}, u) \leq -\alpha\} d\alpha
\leq EX(t_{k(1)}) + K_{16} \kappa(q_0) \quad \text{(by (3.84))}
\]
for a suitable large constant \( K_{16} \). If we are in the first case, we repeat the above procedure with \( q_0 \) replaced by \( q_1 \). That is, we find \( k(2) \) such that \( t_{k(2)} \leq q_1 < t_{k(2)+1} \) etc. We continue to determine \( k(i) \) and \( q_i \) until for the first time \( q_i \) is in the second case, i.e., \( t_{k(i+1)} \leq q_i < t_{k(i+1)} + C_6 k(t_{k(i+1)}) + s_0 + M \). Suppose this first happens at the index \( i_0 \). We then have
\[
EX(q_0) \leq EX(t_{k(1)}) + EX(q_1) + K_{13} \kappa(q_0) \leq \cdots
\leq \sum_{i=1}^{i_0+1} EX(t_{k(i)}) + (K_{13} + K_{16}) \sum_{i=0}^{i_0} \kappa(q_i). \quad (3.96)
\]
Note that by construction, \( q_i < t_k(i) \) for \( 1 \leq i \leq i_0 \), and consequently, \( k(i+1) < k(i) \) for \( i < i_0 \). Therefore the above procedure ends at a finite \( i_0 \), and

\[
(K_{13} + K_{16}) \sum_{i=0}^{i_0} \kappa(q_i) \leq (K_{13} + K_{16}) \left[ \sum_{k : t_k \leq q_0} \kappa(t_k) + \kappa(q_0) \right] \leq K_{17} \left[ q_0 \log q_0 \right]^{1/2}.
\]

In addition we have either \( i_0 = 0 \) and \( q_0 \geq t_k(1) \) or \( i_0 \geq 1 \) and

\[
q_0 = t_k(1) + C_6 \kappa(t_k(1)) + q_1 = \cdots = \sum_{i=1}^{i_0} \left[ t_k(i) + C_6 \kappa(t_k(i)) \right] + q_{i_0} \geq \sum_{i=1}^{i_0+1} t_k(i). \tag{3.97}
\]

Finally, we note that by definition of \( i_0 \), \( q_i - 1 \geq s_0 + M \), and therefore \( t_k(i) \geq M \) for \( i \leq i_0 \). (3.96) and (3.95) now show that

\[
\frac{EX(q_0)}{q_0} \leq \frac{1}{q_0} \sum_{i=1}^{i_0+1} t_k(i) \left[ \liminf_{s \to \infty} \frac{EX(s)}{s} + 2\varepsilon \right]
+ K_{17} \left[ \log q_0 \right]^{1/2} + I[t_k(i_0+1) < M] \frac{\max_{j < M} EX(j)}{q_0},
\]

whence

\[
\limsup_{q \to \infty} \frac{EX(q)}{q} \leq \liminf_{s \to \infty} \frac{EX(s)}{s} + 3\varepsilon.
\]

Thus the limit in (3.93) exists and we can use (3.93) to define \( \lambda(u) \).

We next turn our attention to the second moments. By definition \( 0 \leq X(s) \leq 2\sqrt{d}C_1 s \). With this inequality as a replacement of (11.10) and (11.12) in [Ha], we can start from (3.88) and imitate without essential changes the computations on p. 676 of [Ha] or pp. 21, 22 of [SW] to obtain for any \( M \geq \) some \( s_4 \)

\[
\sum_{k=0}^{\infty} \frac{\sigma^2(X(t_k(M)))}{(M2^k)^2} < \infty.
\]

Since \( t_k(M)/(M2^k) \geq 1 \) (see (3.94)) we even have

\[
\sum_{k=0}^{\infty} \frac{\sigma^2(X(t_k(M)))}{[t_k(M)]^2} < \infty, \tag{3.98}
\]

and hence for any \( \varepsilon > 0 \),

\[
\sum_{k=0}^{\infty} P \left\{ \frac{1}{t_k(M)} |X(t_k(M)) - 2\sqrt{d}C_1 + \lambda(u)| \geq \varepsilon \right\} < \infty.
\]
By (3.83) also
\[
\sum_{k=0}^{\infty} P\{X(t_k(M)) \neq 2\sqrt{dC_1} t_k(M) - h^*(t_k(M), u)\} < \infty,
\]
so that for each fixed $M \geq s_4$ and $u \in S^{d-1}$,
\[
\sum_{k=0}^{\infty} P\left\{\frac{1}{t_k(M)} h^*(t_k(M), u) - \lambda(u) \geq \varepsilon \right\} < \infty. \quad (3.99)
\]

Of course (3.99) implies $h^*(t_k(M), u)/t_k(M) \to \lambda(u)$, almost surely. Since $X(s) \geq 0$ by definition, $2\sqrt{dC_1} - \lambda(u) \geq 0$ in (3.93), and hence $\lambda(u) \leq 2\sqrt{dC_1}$, as claimed. Finally, $\lambda(u) \geq C_4$ follows from Lemma 2 and the almost sure convergence of $h^*(t_k(M), u)/t_k(M)$ to $\lambda(u)$. In fact, (3.16) shows that almost surely $h^*(t_k(M), u) = h(t_k(M), u, -C_5\kappa(t_k(M))) \geq C_4 t_k(M)$ for all large $k$.

Now choose a large $M_0 \geq s_4$ and for some large integer $r$ take $M_i = M_0 2^{i/r}, i = 0, 1, \ldots, r - 1$. Further take $M_r = t_1(M_0)$ and note that $M_{i+1}/M_i \to 2^{1/r}$ as $M_0 \to \infty$ for fixed $r$ and $0 \leq i \leq r - 1$. For given $\eta > 0$ we can therefore first choose $r$ large, such that $1 < 2^{3/r} < 1 + \eta$, and then $M_0$ so large that
\[
2^{1/(2r)} \leq \frac{M_{i+1}}{M_i} \leq 2^{2/r}, \quad 0 \leq i < r - 1.
\]

By (3.94) we may further take $M_0$ so large that
\[
2^{-1/(4r)} \frac{M}{M'} \leq \frac{t_k(M)}{t_k(M')} \leq 2^{1/(4r)} \frac{M}{M'}, \quad \text{for } M \geq M' \geq M_0, \quad k \geq 0.
\]

Once these choices have been made we take for $\{n_j\}_{j \geq 0}$ the collection of all distinct $t_k(M_i), 0 \leq i \leq r - 1, k \geq 0$, arranged in increasing order. Note that $i$ only runs to $r - 1$ here. We claim that the collection $\{n_j\}$ in increasing order is $\{M_0, M_1, \ldots, M_{r-1}, t_1(M_0), \ldots, t_1(M_{r-1}), t_2(M_0), \ldots\}$. To verify this we merely need to check that $t_k(M_0) / t_{k-1}(M_{r-1})$, since the other orderings are obvious from the monotonicity of $t_j(\cdot)$. However, $t_k(M_0) = t_{k-1}(t_1(M_0)) > t_{k-1}(M_{r-1})$ is also easy from $t_1(M_0) \geq 2M_0 > M_{r-1}$. This proves our claim.

By construction we now have for all $j \geq 0$,
\[
2^{1/(4r)} \leq 2^{-1/(4r)} \inf \left\{ \frac{t_k(M_{i+1})}{t_k(M_i)} : k \geq 0, \ 0 \leq i \leq r - 1 \right\} \leq \frac{n_{j+1}}{n_j} \leq 2^{1/r} \sup \left\{ \frac{t_k(M_{i+1})}{t_k(M_i)} : k \geq 0, \ 0 \leq i \leq r - 1 \right\} \leq 2^{3/r} \leq 1 + \eta.
\] \quad (3.100)

The leftmost inequality here shows that $n_j$ increases exponentially with $j$.

It is simple to see that one can choose $\{n_j(\eta')\}$ such that it contains the $\{n_j(\eta)\}$ from some index on, if $\eta' < \eta$, as claimed at the end of the Corollary. In fact if the
$n_j(\eta)$ are constructed by the above method for some $M_0, r$, then one can use the same construction for the $n_j(\eta')$ based on $M'_0, r'$ with $M'_0 = t_k(M_0)$ for some $k$ and $r'$ some integer multiple of $r$.

Next, (3.81) holds, because by (3.99)

$$\sum_{k=0}^{\infty} P\left\{ \left| \frac{1}{n_k} h^*(n_k, u) - \lambda(u) \right| > \varepsilon \right\} = \sum_{i=0}^{r-1} \sum_{k=0}^{\infty} P\left\{ \left| \frac{1}{t_k(M_i)} h^*(t_k(M_i), u) - \lambda(u) \right| > \varepsilon \right\} < \infty. \quad (3.101)$$

Thus also

$$\lim_{k \to \infty} \frac{1}{n_k} h^*(n_k, u) = \lambda(u) \text{ a.s.} \quad (3.102)$$

Now let $0 < \varepsilon \leq C_4/2 \leq \lambda(u)$ and $n\eta\sqrt{dC_1} < \varepsilon/2$. If

$$\frac{1}{n_k} h^*(n_k, u), \frac{1}{n_{k+1}} h^*(n_{k+1}, u) \leq 2\lambda(u) \leq 4\sqrt{dC_1} \quad (3.103)$$

and

$$h^*(n_k, u) - K_{18}\kappa(n_k) \leq h^*(t, u) \leq h^*(n_{k+1}, u) + K_{18}\kappa(n_{k+1}) \quad (3.104)$$

for all $n_k \leq t \leq n_{k+1}$, then, for $k$ large enough and all $n_k \leq t \leq n_{k+1}$

$$\frac{1}{n_k} h^*(n_k, u) - \varepsilon \leq \frac{1}{n_{k+1}} h^*(n_{k+1}, u) - \frac{K_{18}\kappa(n_k)}{n_{k+1}} \leq \frac{1}{t} h^*(t, u)$$

$$\leq \frac{1}{n_k} h^*(n_{k+1}, u) + \frac{K_{18}\kappa(n_{k+1})}{n_k} \leq \frac{1}{n_{k+1}} h^*(n_{k+1}, u) + \varepsilon. \quad (3.105)$$

By choosing $K_{18}$ large enough, and applying (3.84), (3.85), we can make

$$\sum_{k=0}^{\infty} P\{(3.105) \text{ fails for some } t \in [n_k, n_{k+1}]\}$$

$$\leq \sum_{k=0}^{\infty} P\{(3.103) \text{ fails}\} + \sum_{k=0}^{\infty} P\{(3.104) \text{ fails}\}$$

$$\leq 2 \sum_{k=0}^{\infty} P\left\{ \left| \frac{1}{n_k} h^*(n_k, u) - \lambda(u) \right| > \varepsilon \right\} + 2 \sum_{k=0}^{\infty} K_3[n_k]^{-4}$$

$$+ \sum_{k=0}^{\infty} \left[ 8d + K_4(n_{k+1})^d \right] \exp\left[-K_{19}K_{18}^2 \eta^{-1} \log n_k\right]$$

$$< \infty. \quad (3.106)$$

Since $\varepsilon > 0$ can be taken arbitrarily small, this, together with (3.102), proves the almost sure convergence in (3.80). The $L^p$ convergence along all reals in (3.80) follows from the almost sure convergence and the tail estimate (3.83).
4. From half-space to full-space processes.

The goal for this section is to prove that the $B$-particles in the full-space process do not spread faster than in the appropriate half-space process (see Corollary 8 for a precise statement). The first lemma establishes that for every $u \in S^{d-1}$ there are deterministic vectors $V_k$ such that for all $\eta > 0$ there is with a probability close to 1 a $B$-particle in $\mathcal{P}^h(u, -C_5 \kappa((1 + \eta)n_k))$ "near" $V_k$ at time $n_k$, for all large $k$. Here $n_k$ is the $n_k(\eta)$ of Corollary 5 and $(V_k, u)$ has to grow essentially like $h^*(n_k, u) \sim n_k \lambda(u)$ (see (4.1)). Apart from this growth condition the behavior of $V_k$ as a function of $k, u$ is unimportant for us. The only important aspect is that it is non-random, so that we can find, with high probability, a $B$-particle in a non-random location at which $h^*(n_k, u)$ is (almost) achieved. This will be used in the second lemma to concatenate $\mathcal{P}^h(u, -C_5 \kappa(n_k))$ with another process which runs from time $(1 + \eta)n_k$ to $(1 + \eta)n_k + r_k$ with $r_k$ also of order $n_k$. By starting the second process at $(V_k, (1 + \eta)n_k)$ we will be able to assure that a $B$-particle at time $(1 + \eta)n_k + r_k$ in the second process is also a $B$-particle in $\mathcal{P}^h(u, -C_5 \kappa((1 + \eta)n_k + r_k))$.

**Lemma 6.** Let $u \in S^{d-1}$ be fixed, and let $n_k = n_k(\eta)$ be as in Corollary 5. Then, for all $0 < \eta < C_4/(8C_1)$ there exists a deterministic sequence of vectors $\{V_k\} = \{V_k(\eta, u)\}$ such that

$$\langle V_k(\eta, u), u \rangle = n_k(\eta) \lambda(u), \quad (4.1)$$

and such that

$$\sum_{k=0}^{\infty} P\{\text{in } \mathcal{P}^h(u, -C_5 \kappa(n_k)) \text{ there is at time } (1 + \eta)n_k \text{ either no particle at all in } V_k + C(C_2 n_k \eta/4) \text{ or there is an } A\text{-particle in } V_k + C(C_2 n_k \eta/4)\} < \infty. \quad (4.2)$$

**Proof.** Fix $u \in S^{d-1}$ and $\varepsilon > 0$. Let $\sigma$ be a time which is so large that $\sigma \geq s_0$ (with $s_0$ is as in Proposition 3) and such that

$$\left| \frac{1}{\sigma} Eh^*(\sigma, u) - \lambda(u) \right| \leq \frac{1}{4} \varepsilon \quad (4.3)$$

(see (3.27) for $h^*$). Define the further times

$$\sigma_1 = \sigma, \sigma_{j+1} = \sigma + \sigma_j + C_6 \kappa(\sigma_j), \ j \geq 1.$$

Now apply (3.31) with the following choices: $s = \sigma, t = \sigma_j, \gamma = \gamma^*_s = Em^*(\sigma, u)$ (see (3.29) for $m^*$) and $\gamma_t = j Em^*(\sigma, u)$. This yields

$$P\{G(\alpha, \beta, (j + 1) Em^*(\sigma, u), \mathcal{P}^h(u, -C_5 \kappa(\sigma_{j+1})), \sigma_{j+1})$$

$$\geq \int_{0 \leq h < \infty} \int_{m \in \mathbb{R}^d} P\{h^*(\sigma, u) \in dh, m^*(\sigma, u) \in \gamma + dm\}$$

$$P\{G(\alpha - h, \beta - d, j \gamma - m, \mathcal{P}^h(u, -C_5 \kappa(\sigma_j)), \sigma_j)\} - C_8 \sigma^{-K-1},$$
provided (3.30) holds, that is, provided \((\sigma_j + 1) \log(\sigma_j + 1) \leq C_7 \sigma^2\). We start with \(j = r - 1\), then use the case \(j = r - 2\) with \(\alpha, \beta\) replaced by \(\alpha - h\) and \(\beta - d\), respectively, etc., all the way down to \(j = 1\). With \(\langle h_j^* \rangle_{\sigma_j}, j \geq 1\), i.i.d. copies of \((h_j^*(\sigma, u), m_j^*(\sigma, u))\) we obtain

\[
P\{\mathcal{G}(\alpha, \beta, r E m^*(\sigma, u), \mathcal{P}^h(u, -C_5 \kappa(\sigma_r)), \sigma_r)\}
\]

\[
\geq \int_{h_j \geq 0, \; m_j \in \mathbb{R}} \prod_{j=1}^{r-1} P\{h_j^*(\sigma, u) \in dh_j, m_j^*(\sigma, u) \in \gamma + dm_j\}
\times P\{\mathcal{G}\{\alpha - \sum_{j=1}^{r-1} h_j, \beta - (r - 1)d, \gamma - \sum_{j=1}^{r-1} m_j, \mathcal{P}^h(u, -C_5 \kappa(\sigma)), \sigma\}\}
\quad - (r - 1)C_8 \sigma^{-K-1}
\]

\[
= P\{\text{in } \mathcal{P}^h(u, -C_5 \kappa(\sigma)) \text{ there is at time } \sigma \text{ a } B\text{-particle at some } x \text{ with}
\langle x, u \rangle + \sum_{j=1}^{r-1} h_j^* \geq \alpha \text{ and } \|x^+ + \sum_{j=1}^{r-1} m_j^* - \gamma\| \leq \beta - (r - 1)d
\quad - (r - 1)C_8 \sigma^{-K-1}
\}
\geq P\{\sum_{j=1}^{r} h_j^* \geq \alpha, \|\sum_{j=1}^{r} (m_j^* - \gamma)\| \leq \beta - (r - 1)d
\quad - (r - 1)C_8 \sigma^{-K-1},
\] (4.4)

provided

\[
(\sigma_r + 1) \log(\sigma_r + 1) \leq C_7 \sigma^2.
\] (4.5)

It is easy to see by induction that each \(\sigma_j\) is a continuous, increasing function of \(\sigma\) on \([0, \infty)\). We further see by induction that \(\sigma_k \geq k \sigma\) and \(\sigma_j\) increases with \(j\). Finally, we can for any fixed \(\sigma \geq 1\) find a \(K_1 = K_1(\sigma)\) such that

\[
\sigma K_1 2k(\log k + 1) \geq C_6 \kappa(\sigma K_1 k^2(\log k + 1)), \quad k \geq 1,
\]

and \(\sigma_1 \leq \sigma K_1 \log 2\). One more induction argument then shows that for all \(k \geq 1\), \(\sigma_k \leq \sigma K_1 k^2(\log k + 1)\). Now let \(s \geq s_0\) be large and take \(r = \lfloor s^{1/3}\rfloor\). The preceding argument shows that we can fix \(\sigma\) such that \(\sigma_r = s\). Thus for \(j - 1 \leq r\) we have \(\sigma_{j-1} \leq \sigma_r = s\) and \(\sigma_j \leq \sigma + \sigma_{j-1} + C_6 \kappa(s)\). Consequently, \(s = \sigma_r \leq r \sigma + r C_6 \kappa(s) = r \sigma + \lfloor s^{1/3}\rfloor C_6 \kappa(s) = r \sigma + o(s)\), and necessarily \(\sigma \sim s/r \sim s^{2/3}\) for large \(s\). (4.5) is therefore automatically satisfied. If we further take

\[
\alpha = r \sigma [\lambda(u) - \frac{1}{2} \varepsilon],
\]

then, by (4.3) and the fact that \(\text{Variance}(h_j^*) \leq K_2 \sigma^2\) (by (3.83)),

\[
P\{\sum_{j=1}^{r} h_j^* \leq \alpha\} \leq P\{\sum_{j=1}^{r} (h_j^* - Eh_j^*) \leq -r \sigma \varepsilon/4\} \leq \frac{K_3}{r \varepsilon^2}.
\] (4.6)
Further, fix $s_5$ so large that $2s\varepsilon \geq r\sigma \varepsilon \geq (1/2)s\varepsilon \geq 2rd \sim 2s^{1/3}d$ for $s \geq s_5$. Then we have similarly to (4.6), for $s \geq s_5$ and $\beta = s\varepsilon$

$$P\{\| \sum_{j=1}^{r} (m_j^* - \gamma) \| > \beta - (r - 1)d \} \leq P\{\| \sum_{j=1}^{r} (m_j^* - \gamma) \| > r\sigma \varepsilon /4 \} \leq \frac{K_4}{r \varepsilon^2}. \quad (4.7)$$

The last two inequalities provide us with a lower bound for the right hand side of (4.4). We conclude that for $s \geq s_5$

$$P\{G(\alpha, \beta, rE\theta^*(\sigma, u), \mathcal{P}^h(u, -C_5\kappa(\sigma_r), \sigma_r)) \}
\geq 1 - \frac{(K_3 + K_4)}{r \varepsilon^2} - (r - 1)C_8\sigma^{-K-1} \geq 1 - \frac{K_5}{s^{1/3} \varepsilon^2} \quad (4.8)$$

(use any $K \geq 1$). Let $n_j(\eta)$ be as in Corollary 5, and take $s = n_k = n_k(\eta)$. In agreement with our previous choice for $r, \sigma$ we then take $r = \lfloor n_k^{-1/3}(\eta) \rfloor$ and $\sigma$ such that $\sigma_r = n_k(\eta)$. Then, by going over to the complementary event in (4.8), we find for any $\eta > 0$, that

$$\sum_{k=0}^{\infty} P\{\text{in } \mathcal{P}^h(u, -C_5\kappa(n_k)) \text{ there is at time } n_k \text{ no } B\text{-particle}
\text{ in } \Gamma(n_k[\lambda(u) - \frac{1}{4}\varepsilon], n_k\varepsilon, rE\theta^*(\sigma, u))\}
\leq \sum_{k=0}^{\infty} \frac{K_5}{n_k^{1/3} \varepsilon^2} < \infty \quad (4.9)$$

(recall that the $n_j$ grow exponentially). But (3.81) says in particular that

$$\sum_{k=0}^{\infty} P\{\text{in } \mathcal{P}^h(u, -C_5\kappa(n_k)) \text{ there is at time } n_k \text{ a } B\text{-particle}
\text{ in } \Gamma(n_k[\lambda(u) + \frac{1}{4}\varepsilon], n_k\varepsilon, rE\theta^*(\sigma, u))\}
< \infty. \quad (4.10)$$

We now take

$$V_k = V_k(\eta, u) = n_k(\eta)\lambda(u)u + rE\theta^*(\sigma, u). \quad (4.11)$$

Since $m^*$ is orthogonal to $u$ (by definition), this choice of $V_k$ satisfies (4.1). Moreover, (4.9) and (4.10) together give

$$\sum_{k=0}^{\infty} P\{\text{in } \mathcal{P}^h(u, -C_5\kappa(n_k)) \text{ there is at time } n_k \text{ no } B\text{-particle}
\text{ at any site } x \in V_k + C(2\sqrt{d}n_k\varepsilon)\}
\leq \sum_{k=0}^{\infty} P\{\text{in } \mathcal{P}^h(u, -C_5\kappa(n_k)) \text{ there is at time } n_k \text{ no } B\text{-particle at any site } x
\text{ with } \langle x, u \rangle \in \left[ n_k[\lambda(u) - \frac{\varepsilon}{4}], n_k[\lambda(u) + \frac{\varepsilon}{4}] \right], \| x^\perp - rE\theta^*(\sigma, u) \| \leq n_k \varepsilon \}
< \infty. \quad (4.12)$$
The convergence of the sums in (4.12) shows that almost surely, for all large \( n_k(\eta) \), there is in \( \mathcal{P}^h(u, -C_5\kappa(n_k)) \) a \( B \)-particle in \( V_k + \mathcal{C}(2\sqrt{dn_k}\varepsilon) \) at time \( n_k(\eta) \).

We claim that this implies that if we take \( \varepsilon = C_2\eta/(16d) \), then, in \( \mathcal{P}^h(u, -C_5\kappa(n_k)) \) at time \((1 + \eta)n_k\), all occupied sites in \( V_k + \mathcal{C}(C_2n_k\eta/4) \) are occupied by \( B \)-particles (and there are such occupied sites). More precisely, we claim that (4.2) holds. To see this we shall apply Lemma 4 with the following choices: \( s = n_k, \bar{s} = (1 + \eta)n_k, t = (1 + \eta)n_k \) and finally \( y(n_k) \) is the location of any \( B \)-particle in \( \mathcal{P}^h(u, -C_5\kappa(n_k)) \) at time \( n_k \) in the set \( V_k + \mathcal{C}(C_2n_k\eta/(8\sqrt{d})) \), if such a \( B \)-particle exists. If several such \( B \)-particles exist we pick the location of one of them according to some deterministic rule chosen in advance. On the event that no such \( B \)-particle exists we cannot apply Lemma 4, but this does not cause any problems, because (4.12) already tells us that

\[
\sum_{k=0}^{\infty} P\{\text{no choice for } y(n_k) \text{ exists} \} < \infty. \tag{4.13}
\]

If \( y(n_k) \) exists, then there is automatically a particle in \( \mathcal{P}^h(u, -C_5\kappa(n_k)) \) at time \( n_k \) at \( y(n_k) \in V_k + \mathcal{C}(C_2n_k\eta/(8\sqrt{d})) \). If this particle does not move a distance \( > C_2n_k\eta/8 \) during \([n_k, (1 + \eta)n_k]\), then it is in \( y(n_k) + \mathcal{C}(C_2n_k\eta/8) \subset V_k + \mathcal{C}(C_2n_k\eta/4) \) at time \((1 + \eta)n_k\). We recall further that all particles in \( \mathcal{P}^h(u, -C_5\kappa(n_k)) \) are also particles in \( \mathcal{P}^f \). It follows that the \( k \)-th summand in (4.2) is bounded by the \( k \)-th summand in (4.13) plus

\[
P\{\|S_{n_k\eta}\| > C_2n_k\eta/8\} + P\{B^h(y(n_k), n_k; u, -C_5\kappa(n_k)) \cap \mathcal{K}(y(n_k))\} \tag{4.14}
\]

(see (3.73) for \( \mathcal{K}(y) \)). The first probability in (4.14) is at most \( K_6 \exp[-K_7n_k\eta] \) by (2.42) in [KSa]. The last probability in (4.14) is by Lemma 4 at most

\[
P\{y(n_k) \notin \mathcal{C}(2C_1n_k)\} + P\{\langle y(n_k), u \rangle < \frac{1}{2}C_4n_k\} + n_k^{-K-1}. \tag{4.15}
\]

The first probability in (4.15) is \( O(n_k^{-K-1}) \) by the estimates used for (3.59). The second probability in (4.15) is zero, because, by construction, \( y(n_k) \in V_k + \mathcal{C}(C_2n_k\eta/(8\sqrt{d})) \), so that

\[
\langle y(n_k), u \rangle \geq \langle V_k, u \rangle - C_2n_k\eta/8
\]

\[
= n_k\lambda(u) - C_2n_k\eta/8 \geq n_k(C_4 - C_2\eta/8) \quad \text{(see Corollary 5)} \geq \frac{1}{2}C_4n_k.
\]

It follows that the sum of (4.15) over \( k \) is also finite, and this proves (4.2). \( \blacksquare \)

We can now show how to concatenate two processes as outlined before the last lemma.

**Lemma 7.** Define

\[
H(t, u) = h(t, u, -\infty) = \max\{\langle x, u \rangle : x \text{ is occupied by a } B \text{-particle in } \mathcal{P}^f \text{ at time } t\}. \tag{4.16}
\]
Assume that for some fixed $u \in S^{d-1}$ and $\mu \geq 0$

$$P\{\limsup_{t \to \infty} \frac{1}{t} H(t, u) \geq \mu\} > 0. \quad (4.17)$$

Then

$$\lambda(u) \geq \mu. \quad (4.18)$$

**Proof.** We divide the proof into 4 steps. Without loss of generality we assume $\mu > 0$.

**Step 1.** For each small $\eta > 0$ we choose

$$K_1 > 2\sqrt{dC_1} \geq \lambda(u) \text{ and } K_2 = \frac{1}{4C_1\sqrt{dK_1}}. \quad (4.19)$$

We then define

$$m_k = m_k(\eta) = K_2 n_k(\eta), \quad (4.20)$$

where $n_k = n_k(\eta)$ is as in Corollary 5. We take $\eta_0 = \eta_0(\varepsilon) > 0$ so small that

$$1 + \eta_0 \leq \frac{\mu - \varepsilon/2}{\mu - 3\varepsilon/4}.$$

Note that these definitions imply that for $\eta \leq \eta_0$,

$$\frac{m_{k+1}}{m_k} = \frac{n_{k+1}}{n_k} \leq 1 + \eta \leq \frac{\mu - \varepsilon/2}{\mu - 3\varepsilon/4}. \quad (4.21)$$

Further, for small $\varepsilon > 0$, define the events

$$L_k(\eta, \mu - \varepsilon)$$

$$= \left\{ \text{in } \mathcal{P} \text{ there is a } B\text{-particle in the half-space } S(u, m_k(\mu - \varepsilon)) \text{ at time } m_k \right\}$$

$$= \{H(m_k, u) \geq m_k(\mu - \varepsilon)\}.$$

In this step we shall show that for fixed $\varepsilon > 0$ and all $0 < \eta \leq \eta_0(\varepsilon)$,

$$\sum_{k=0}^{\infty} P\{L_k(\eta, \mu - \varepsilon)\} = \infty. \quad (4.22)$$

To prove this we shall show that

$$P\{L_k(\eta, \mu - \varepsilon) \text{ occurs for infinitely many } k\} > 0. \quad (4.23)$$

(4.22) then follows from the Borel-Cantelli lemma. Now, (4.17) says that for every $\varepsilon > 0$

$$P\{\text{for infinitely many } k, H(t, u) > (\mu - \varepsilon/2)t \text{ for some } t \in [m_k, m_{k+1}]\} > 0. \quad (4.24)$$
SHAPE THEOREM FOR SPREAD OF AN INFECTION

However, by (3.85) with \( h^* \) replaced by \( H \) (this amounts to taking \( C_5 = \infty \), which does not influence the estimate (3.85)) and with \( \alpha = (\varepsilon/4)m_{k+1} \leq (\mu - \varepsilon/2)m_k - (\mu - \varepsilon)m_{k+1} \) (see (4.21))

\[
P\{H(t, u) > (\mu - \varepsilon/2)t \text{ for some } t \in [m_k, m_{k+1}] \} \leq P\{ \sup_{r \in [m_k, m_{k+1}]} [H(r, u) - H(m_{k+1}, u)] \geq (\mu - \varepsilon/2)m_k - (\mu - \varepsilon)m_{k+1} \}
\]

\[
\leq K_3(\varepsilon, \eta)[m_{k+1}]^{-K}.
\]

In particular, by Borel-Cantelli, the event in the left hand side here occurs almost surely only finitely often. Together with (4.24) this shows that

\[
P\{\text{for infinitely many } k, H(m_{k+1}, u) \geq (\mu - \varepsilon)m_{k+1} \} > 0.
\]

This is the required (4.23).

**Step 2.** The remaining steps are based on (4.22) only; (4.17) itself is not needed. With \( V_k = V_k(\eta, u) \) as in (4.11) we define an auxiliary process \( \mathcal{Q}_k = \mathcal{Q}_k(\eta, u) \) which is more or less the full-space process started at the deterministic space time point \( (V_k, (1 + \eta)n_k) \). The only difference is that \( \mathcal{Q}_k \) only uses the particles which are at time 0 in the “slab”

\[
\{ x : -n_k/K_1 \leq \langle x, u \rangle - n_k\lambda(u) < K_1n_k \},
\]

with \( K_1 \) given by (4.19). Thus \( \mathcal{Q}_k \) is defined only from time \((1 + \eta)n_k \) on. At time \((1 + \eta)n_k \) it has at any \( x \) only the particles which started at time 0 in the set (4.25). If no such particles exist, then there never are any particles in the process \( \mathcal{Q}_k \). Otherwise, let \( z_k \) be the nearest site to \( V_k \) which is occupied at time \((1 + \eta)n_k \) by some particle, which at time 0 was in (4.25). The types of all particles in \( \mathcal{Q}_k \) at time \((1 + \eta)n_k \) are reset to type \( A \), except for the particles at \( z_k \), which are reset to type \( B \). From time \((1 + \eta)n_k \) the process then develops by our standard rules. Even though the process \( \mathcal{Q}_k \) is defined for all times in \([ (1 + \eta)n_k, \infty) \) we are only interested in what happens during \([ (1 + \eta)n_k, (1 + \eta)n_k + m_k ] \). Specifically, we define the events

\[
\mathcal{M}_k = \mathcal{M}_k(\eta, \mu - \varepsilon) = \{ \text{in } \mathcal{Q}_k \text{ there is a } B \text{-particle in the half-space} \}
\]

\[
\mathcal{S}(u, n_k\lambda(u) + m_k(\mu - \varepsilon)) \text{ at time } (1 + \eta)n_k + m_k \}.
\]

In this step we shall prove that

\[
\sum_{k=0}^{\infty} P\{\mathcal{M}_k \} = \infty.
\]

To this end let us shift the event \( \mathcal{L}_k \) by \((1 + \eta)n_k \) in time and by \( V_k \) in space. Then \( \mathcal{L}_k \) goes over into the event

\[
\mathcal{L}_k' := \{ \text{in the full-space process started at } (V_k, (1 + \eta)n_k) \text{ there is a } B \text{-particle in the half-space} \}
\]

\[
\mathcal{S}(u, n_k\lambda(u) + m_k(\mu - \varepsilon)) \text{ at time } (1 + \eta)n_k + m_k \}.
\]
$\mathcal{L}'_k \setminus \mathcal{M}_k$ can occur only if one of the following two events occurs:

\{ at time $((1 + \eta) n_k)$, some particle at the nearest occupied site to $V_k$ in the full-space process started at time 0 outside the set (4.25) \}, \hspace{1cm} (4.28)

or

\{ in the full-space process started at $(V_k, (1 + \eta) n_k)$ there is a particle which starts at time 0 outside the set (4.25) and which coincides with a $B$-particle during $[(1 + \eta) n_k, (1 + \eta) n_k + m_k]$ \} \hspace{1cm} (4.29)

(compare the argument for (3.47)). It follows that

$$P\{\mathcal{L}'_k \setminus \mathcal{M}_k\} \leq P\{\text{(4.28) or (4.29) occurs}\}.$$  

But

$$P\{\text{(4.28) occurs}\} \leq P\{\text{nearest occupied site to } V_k \text{ in } \mathcal{P} \text{ at time } (1 + \eta) n_k \text{ has distance more than } K_4 \log k \text{ from } V_k\} + P\{\text{some particle which starts at time 0 outside the set (4.25) is in } V_k + \mathcal{C}(K_4 \log k) \text{ at time } (1 + \eta) n_k\}. \hspace{1cm} (4.30)$$

Also,

$$P\{\text{(4.29) occurs}\} \leq P\{\text{in the full-space process started at } (V_k, (1 + \eta) n_k) \text{ there are } B\text{-particles outside } V_k + \mathcal{C}(2C_1 m_k) \text{ at some time during } [(1 + \eta) n_k, (1 + \eta) n_k + m_k]\} + P\{\text{some particle which starts at time 0 outside the set (4.25) visits } V_k + \mathcal{C}(2C_1 m_k) \text{ during } [0, (1 + \eta) n_k + m_k]\}. \hspace{1cm} (4.31)$$

The first probability in the right hand side of (4.30) can be made $O(k^{-K})$ for any given $K$, by choosing $K_4$ large (compare (3.26)). The second probability in the right hand side of (4.30) is for large $k$ no more than the second probability in the right hand side of (4.31). To estimate the latter, we merely point out that a particle which starts at some $z$ outside the set (4.25) and visits $V_k + \mathcal{C}(2C_1 m_k)$ during $[0, (1 + \eta) n_k + m_k]$ has to move over a distance of at least

$$||z - V_k|| - 2C_1 m_k \geq d^{-1/2} ||(z - V_k), u|| - 2C_1 m_k \geq d^{-1/2} ||(z, u) - n_k \lambda(u)|| - 2C_1 m_k \geq n_k/(\sqrt{dK_1}) - 2C_1 m_k \geq n_k/(2\sqrt{dK_1}),$$
by virtue of our choice of \( m_k \). We leave it to the reader to use this to check that the last probability in (4.31) is \( O([n_k]^{-K}) \) (see also the estimates in (3.24) and (3.50) or (3.76)). Finally, the first probability in the right hand side of (4.31) equals

\[
P\{\text{in } \mathcal{P}^f \text{ there are } B\text{-particles outside } \mathcal{C}(2C_1m_k) \text{ during } [0, m_k]\},
\]

and this is \( O([m_k]^{-K-2}) \), as in (3.25) and the lines following it. It follows from these estimates that \( \sum_k P\{\mathcal{L}'_k \setminus \mathcal{M}_k\} < \infty \). In view of (4.22) and the fact that \( P\{\mathcal{L}'_k\} = P\{\mathcal{L}_k\} \), this implies (4.27).

**Step 3.** In this step we show that

\[
P\{\mathcal{M}_k \text{ occurs for infinitely many } k\} = 1.
\]

(4.32)

This is an easy application of Borel-Cantelli, because \( \mathcal{M}_k \) and \( \mathcal{M}_\ell \) depend on particles which start at disjoint sets of sites (and are therefore independent) as soon as the set (4.25) and the corresponding set with \( k \) replaced by \( \ell \) are disjoint. If \( \ell > k \), this is the case if \( n_k(\lambda(u) + K_1) < n_\ell(\lambda(u) - 1/K_1) \) and similarly if \( k > \ell \). In particular, there is some integer \( K_5 = K_5(\eta) \) such that \( \mathcal{M}_k \) and \( \mathcal{M}_\ell \) are independent as soon as \( |k - \ell| \geq K_5 \). Moreover, by (4.27), there is some integer \( j \in [0, K_5 - 1] \) such that

\[
\sum_{k \equiv j \pmod{K_5}} P\{\mathcal{M}_k\} = \infty.
\]

Thus (4.32) is true.

**Step 4.** We now complete the proof of the lemma by showing that, almost surely, for all large \( k \) for which \( \mathcal{M}_k \) occurs, also

\[
\{\text{in } \mathcal{P}^h(u, -C_5((1 + \eta)n_k + m_k)) \text{ there is a } B\text{-particle in the half-space }\]

\[
S(u, n_k\lambda(u) + m_k(\mu - \varepsilon)) \text{ at time } (1 + \eta)n_k + m_k\}
\]

\[
= \{h^*((1 + \eta)n_k + m_k, u) \geq n_k\lambda(u) + m_k(\mu - \varepsilon)\} \quad (4.33)
\]

occurs. This will indeed complete the proof, since we already know from Corollary 5 that \( ((1 + \eta)n_k + m_k)^{-1} h^*((1 + \eta)n_k + m_k, u) \to \lambda(u) \). Thus (4.32) and (4.33) will imply, for all \( \varepsilon > 0, 0 < \eta < \eta_0(\varepsilon) \),

\[
\lambda(u) \geq \liminf_{k \to \infty} \left[ \frac{n_k}{(1 + \eta)n_k + m_k}\lambda(u) + \frac{m_k}{(1 + \eta)n_k + m_k}(\mu - \varepsilon) \right]
\]

\[
= \frac{1}{1 + \eta + K_2}\lambda(u) + \frac{K_2}{1 + \eta + K_2}(\mu - \varepsilon),
\]

and hence

\[
\lambda(u) \geq \frac{K_2}{\eta + K_2}(\mu - \varepsilon). \quad (4.34)
\]
Now to prove (4.33), we write, as in the lines following (4.25), $z_k$ for the nearest site to $V_k$ at time $(1 + \eta)n_k$ which is occupied by a particle which started at time 0 in (4.25). We already proved that, almost surely, (4.28) occurs only finitely often. Thus, except for finitely many $k$, $z_k$ actually equals the nearest occupied site to $V_k$ at time $(1 + \eta)n_k$ in $P_f$. Since the set (4.25) is contained in $S(u, 0) \subset S(u, -C_5\kappa(n_k))$, $z_k$ is also the nearest occupied site to $V_k$ at time $(1 + \eta)n_k$ in $P_h(u, -C_5\kappa(n_k))$.

By virtue of Lemma 6, we further know that, a.s. for all large $k$, $z_k$ is occupied by $B$-particles at time $(1 + \eta)n_k$ in $P_h(u, -C_5\kappa(n_k))$ for all large $k$. By using the monotonicity property of Lemma C we conclude that, almost surely, for all large $k$ all the $B$-particles in $Q_k$ at time $(1 + \eta)n_k + m_k$ are also $B$-particles in $P_h(u, -C_5\kappa((1 + \eta)n_k + m_k))$. In particular,

$$h^*((1 + \eta)n_k + m_k, u) \geq n_k\lambda(u) + m_k(\mu - \varepsilon)$$

for all large $k$ for which $\mathcal{M}_k$ occurs. This is the required (4.33).

**Corollary 8.** For every unit vector $u$

$$\lim_{t \to \infty} \frac{1}{t} H(t, u) = \lambda(u) \text{ almost surely and in } L^p \text{ for all } p > 0. \quad (4.35)$$

($t$ runs through the reals here). Moreover, for $n_k = n_k(\eta)$ as in Corollary 5, we have for any $\delta > 0$ and $\eta > 0$,

$$\sum_{k=0}^{\infty} P\{|\frac{1}{n_k}H(n_k, u) - \lambda(u)| > \delta\} < \infty. \quad (4.36)$$

**Proof.** By the monotonicity property of Lemma C

$$H(t, u) \geq h^*(t, u) \text{ on the event } \{\|x_0\| \leq C_5\kappa(t)/\sqrt{d}\} \quad (4.37)$$

(see also the lines after (3.48)). Thus, by the estimate (3.26)

$$\liminf_{t \to \infty} \frac{1}{t} H(t, u) \geq \lim_{t \to \infty} \frac{1}{t} h^*(t, u) = \lambda(u)$$

(see Corollary 5). In the other direction, we have from Lemma 7 that

$$P\{\limsup_{t \to \infty} \frac{1}{t} H(t, u) \geq \mu\} = 0 \text{ for all } \mu > \lambda(u).$$

This proves the almost sure convergence in (4.35). The $L^p$ convergence follows from the almost sure convergence and the tail estimate

$$P\{H(s, u) \geq \alpha\} \leq \exp[-K_1\alpha] \text{ for } \alpha \geq 2\sqrt{d}C_1s, \quad s \geq s_3, \quad (4.38)$$

which can be proven in the same way as (3.83) (or we can take $C_5 = \infty$ in (3.83)).
As for (4.36), we have by (4.37), (3.81) and an estimate like (3.26) that
\[
\sum_{k=0}^{\infty} P\left\{ \frac{1}{n_k} H(n_k, u) < \lambda(u) - \delta \right\} < \infty. \tag{4.39}
\]

For the other direction, we begin with an indirect argument. Assume, to derive a contradiction, that for some \( \delta > 0 \) and \( 0 < \eta \leq C_4/(8C_1) \)
\[
\sum_{k=0}^{\infty} P\left\{ \frac{1}{m_k} H(m_k, u) > \lambda(u) + \delta/2 \right\} = \infty,
\]
with \( m_k = m_k(\eta) \) as in (4.20). This is just (4.22) with \( \mu - \varepsilon \) replaced by \( \lambda(u) + \delta/2 \).
By steps 2-4 of the proof of Lemma 7 we then have that (4.34), again with \( \mu - \varepsilon \) replaced by \( \lambda(u) + \delta/2 \), holds. This is impossible for \( \eta < K_2\delta/(2\lambda(u)) \). Thus for all \( \delta > 0, 0 < \eta < C_4/(8C_1) \land K_2\delta/(2\lambda(u)) \), it is the case that
\[
\sum_{k=0}^{\infty} P\left\{ \frac{1}{m_k} H(m_k, u) > \lambda(u) + \delta/2 \right\} < \infty. \tag{4.40}
\]

Finally, for given \( k \), let \( \ell = \ell(k) \) be determined by \( m_\ell < n_k \leq m_{\ell+1} \). We now use that
\[
P\{H(n_k, u) > n_k(\lambda(u) + \delta)\} \leq P\{H(m_{\ell+1}, u) > m_{\ell+1}(\lambda(u) + \delta/2)\} + P\{H(m_{\ell+1}, u) - H(n_k, u) \leq m_{\ell+1}(\lambda(u) + \delta/2) - n_k(\lambda(u) + \delta)\}. \tag{4.41}
\]

But, by (3.84) (with \( C_5 \) taken to be infinity) we have
\[
P\{\inf_{r \leq t} H(s + r, u) - H(s, u) \leq -\alpha\} \leq K_3 s^{-K} + 8d \exp\left[ -\frac{K_2 \alpha^2}{t + \alpha} \right], \quad \alpha \geq 0. \tag{4.42}
\]
Moreover, \( m_{\ell+1} \leq (1 + \eta)m_\ell \leq (1 + \eta)n_k \) (see (4.21)). Therefore the second term in the right hand side of (4.41) is at most
\[
P\{H(m_{\ell+1}, u) - H(n_k, u) \leq n_k[(1 + \eta)(\lambda(u) + \delta/2) - (\lambda(u) + \delta)] \leq -n_k\delta/4\}
\leq K_3 n_k^{-K} + K_6 \exp[-K_7 n_k \delta^2/(\eta + \delta)],
\]
provided
\[
\eta < \min\left\{ \frac{C_4}{8C_1}, \frac{K_2\delta}{2\lambda(u)}, \frac{\delta}{4(\lambda(u) + \delta/2)} \right\}. \tag{4.43}
\]
It follows that under this last condition
\[
\sum_{k=0}^{\infty} P\{H(n_k, u) > n_k(\lambda(u) + \delta)\}
\leq \sum_{k=0}^{\infty} P\{H(m_{\ell(k)+1}, u) > m_{\ell(k)+1}(\lambda(u) + \delta/2)\} + O(1).
\]
The right hand side here is finite by virtue of (4.40), because \( m(k) = K_2n(k) < n_k \leq K_2n(k+1) \) forces \(|\ell(k) - k| \leq K_8\) for some \( K_8 \) which is independent of \( k \) (see (3.10)). Finally, we may drop the condition (4.43), because if \( \eta \) does not satisfy this condition, but \( \eta' \) does satisfy this condition, then we may choose \( \{n_k(\eta')\} \) so that it contains the tail of \( \{n_k(\eta)\} \), by Corollary 5. By this inclusion and by what we just proved

\[
\sum_{k=0}^\infty P\{H(n_k(\eta), u) > n_k(\eta)(\lambda(u) + \delta)\} \\
\leq \sum_{k=0}^\infty P\{H(n_k(\eta'), u) > n_k(\eta')(\lambda(u) + \delta)\} + O(1) < \infty.
\]

5. Proof of the shape theorem. Now that we have shown that the spread of the \( B \)-particles in the full space process has a definite speed in each direction, the half-space processes are no longer of importance. In fact Corollary 8 contains Theorem 1 in the one-dimensional case (with \( B_0 = [-\lambda(e_1), \lambda(e_1)] \)). For the higher dimensional case, we shall show in this section how to go from the existence of \( \lim_{t \to \infty} (1/t)H(t, u) \) for all \( u \in S^{d-1} \) to the full shape theorem. This should work for a fairly general class of processes. The idea to derive the shape theorem via results on the propagation of half-spaces we learned from [GG]. However, the details in our case differ from those in [GG].

The remaining problem in dimension \( d > 1 \) is that even if we know that \( H(t, u) \) grows at rate \( \lambda(u) \), it only tells us that there exist \( B \)-particles at time \( t \) at some random site \( x_t \) for which \( \langle x_t, u \rangle \sim t\lambda(u) \). It does not tell us where the points \( x_t \) near the hyperplane \( \{x : \langle x, u \rangle = t\lambda(u)\} \) are. In particular, it does not guarantee that we can find \( x_t \) which converge in direction to a prescribed unit vector, i.e., for given \( v \in S^{d-1} \) we do not know whether we can choose \( x_t \) such that \( x_t/\|x_t\|_2 \to v \).

To attack this problem we first write down the conjectured limiting shape \( B_0 \) in terms of the function \( \lambda(\cdot) \) on \( S^{d-1} \). This conjectured \( B_0 \) is convex (for trivial reasons). We then show that we can guarantee \( x_t/\|x_t\|_2 \to v \) if \( v \) corresponds to a so-called exposed point of the convex set \( B_0 \). Using some further properties of convex sets, as well as approximate convexity properties of the set of points which can be reached by the \( B \)-particles in a large time, we can then show that the limiting shape result (1.3) holds.

The convergence result (4.35) suggests that the limit set \( B_0 \) in (1.3) should be given by

\[
B_0 = \{z \in \mathbb{R}^d : \langle z, u \rangle \leq \lambda(u) \text{ for all } u \in S^{d-1}\}. \tag{5.1}
\]

Clearly this set \( B_0 \) is a closed convex set. In fact it is also bounded and hence compact, because \( \lambda(u) \leq 2\sqrt{d}C_1 \) for all \( u \). The origin is an interior point of \( B_0 \) because \( \lambda(u) \geq C_4 \). We call a point \( w \in \partial B_0 \) an exposed point of \( B_0 \) if there exists a supporting hyperplane \( \{z \in \mathbb{R}^d : \langle a, z \rangle = b\} \) of \( B_0 \) which contains \( w \), but no other point of \( B_0 \). Thus

\[
\langle a, w \rangle = b \text{ but } \langle a, z \rangle < b \text{ for all } z \in B_0 \setminus \{w\}. \tag{5.2}
\]
Note that this forces $a \neq 0$. We now show that $P^f$ indeed grows in the direction of an exposed point at the rate which is necessary for (1.3).

**Lemma 9.** Let $w$ be an exposed point of $B_0$ and let $(a, b) \in \mathbb{R}^d \times \mathbb{R}$ satisfy (5.2). Let $u = a/\|a\|_2$. Then, there exists a sequence $\varepsilon_n \downarrow 0$ such that

$$P\{N_n(w, \varepsilon_n) \text{ occurs for all large integers } n\} = 1,$$

where

$$N_n(w, \varepsilon) := \{\text{in } P^f \text{ there are at time } (1 + 8\varepsilon/C_2)n \text{ occupied sites in } nw + C(2\varepsilon n) \text{ and all these sites are in fact occupied by } B\text{-particles at time } (1 + 8\varepsilon/C_2)n\}.$$  

Also, define

$$O_n(w, \delta) = \{\text{in } P^f \text{ there is at time } n \text{ a } B\text{-particle in } nw + C(\delta n)\}.$$

Finally, let $n_k = n_k(\eta)$ be as in Corollary 5. Then for all $\delta, \eta > 0$

$$\sum_{k=0}^{\infty} \left[1 - P\{O_{n_k(\eta)}(w, \delta)\}\right] < \infty. \tag{5.5}$$

**Proof.** Order the vertices of $\mathbb{Z}^d$ in some deterministic way, for instance in the lexicographic way. Let $x_t$ be the first vertex $x$ in this order which is occupied by a $B$-particle in $P^f$ at time $t$ and with $\langle x, u \rangle = H(t, u)$. By (4.35), almost surely,

$$\frac{1}{t}\langle x_t, u \rangle \to \lambda(u) = \lim_{t \to \infty} \frac{1}{t}H(t, u) \tag{5.6}$$

as $t \to \infty$. Moreover, by (4.36), for each $\delta > 0, \eta > 0$

$$\sum_{k=0}^{\infty} P\{|\frac{1}{n_k}x_n - \lambda(u)| > \delta\} < \infty. \tag{5.7}$$

We want to show that for each $\delta > 0$

$$P\left\{\|\frac{1}{n}x_n - w\| \leq \delta \text{ for all large integers } n\right\} = 1. \tag{5.8}$$

Note that $w \in B_0$ implies

$$\langle w, u \rangle \leq \lambda(u). \tag{5.9}$$

Recall next that $P\{x_n \notin C(2C_1n)\} \leq K_6n^{-K-d-1}$, by virtue of (3.49) or the estimates for (3.25). So,

$$P\{x_n \in C(2C_1n) \text{ for all large } n\} = 1. \tag{5.10}$$
Also
\[\sum_{k=0}^{\infty} P\{x_{n_k} \notin C(2C_1n_k)\} < \infty. \quad (5.11)\]

So, we can ignore the events \(\{x_n \notin C(2C_1n)\}\).

Next, let \(v \in S^{d-1}\) be a unit vector which is not a multiple of \(w\). We claim that there exists some \(\delta = \delta(v) > 0\) such that
\[P\left\{ \left\| \frac{x_n}{\|x_n\|_2} - v \right\| < \delta \text{ i.o.} \right\} = 0 \quad (5.12)\]
and
\[\sum_{k=0}^{\infty} P\left\{ \left\| \frac{x_{n_k}}{\|x_{n_k}\|_2} - v \right\| < \delta \right\} < \infty \quad (5.13)\]
(i.o. stands for infinitely often). To prove this, note first that (5.12) holds if \(\langle v, u \rangle = 0\), because\[\liminf_{n \to \infty} \langle \frac{x_n}{\|x_n\|_2}, u \rangle \geq \frac{\lambda(u)}{\limsup_{n \to \infty} \|x_n\|_2/n} \geq \frac{C_4}{2\sqrt{d}C_1}\]
by virtue of (5.6), (5.10) and the fact the \(\lambda(u) \in [C_4, 2\sqrt{d}C_1]\). Similarly, (5.13) holds if \(\langle v, u \rangle = 0\), by virtue of (5.7) and (5.11).

To take care of other vectors \(v\), define for any \(y \in \mathbb{R}^d \setminus \{0\}\), with \(\langle y, u \rangle \neq 0\), \(\tilde{y}\) = the unique multiple of \(v\) which satisfies \(\langle \tilde{y}, u \rangle = b/\|a\|_2\).

In particular, \(\tilde{y}\) lies in the in the supporting hyperplane \(\{z : \langle a, z \rangle = b\}\). Now, by assumption \(\tilde{v} \neq w\), so that \(\tilde{v} \notin B_0\). By definition of \(B_0\) this means that there exists some \(u' \in S^{d-1}\) such that \(\langle \tilde{v}, u' \rangle > \lambda(u')\). We can then find \(\delta > 0\) and \(\eta > 0\) such that \(\langle z, u' \rangle > (1 + \eta)\lambda(u')\) for all \(z \in S^{d-1}\) with \(\|z - v\| < \delta\). Thus, if
\[\left\| \frac{x_n}{\|x_n\|_2} - v \right\| < \delta,\]
then
\[\langle \tilde{x}_n, u' \rangle = \langle \frac{x_n}{\|x_n\|_2}, u' \rangle > (1 + \eta)\lambda(u'). \quad (5.14)\]

In addition, by (5.6) and (5.9),
\[\lim_{n \to \infty} \frac{1}{n} \langle x_n, u \rangle = \lambda(u) \geq \langle w, u \rangle = \frac{b}{\|a\|_2} \quad (\text{see (5.2))},\]
while, by definition of \(\tilde{y}\),
\[\langle \tilde{x}_n, u \rangle = \frac{b}{\|a\|_2}.\]
Moreover, we must have
\[ \|a\|_2 \langle w, u \rangle = b > 0 \] (5.15)
by (5.2) and the fact that \( \mathbf{0} \in B_0 \). Consequently, \( x_n = \gamma_n \tilde{x}_n \) for some reals \( \gamma_n \) which satisfy \( \gamma_n/n \to 1 \). Together with (5.14) this would imply
\[ \langle x_n, u' \rangle > n(1 + \eta/2) \lambda(u') \]
for large \( n \). But, \( P\{\langle x_n, u' \rangle > n(1 + \eta/2) \lambda(u') \text{ i.o.}\} = 0 \), by virtue of (4.35) with \( u \) replaced by \( u' \) and the fact that \( H(n, u') \geq \langle x_n, u' \rangle \) (by definition of \( H \)). Thus (5.12) holds for the chosen \( \delta \). Similarly, (5.13) follows by means of (5.7) with \( u' \) instead of \( u \).

Now, for any \( \varepsilon > 0 \) the compact set
\[ W(\varepsilon) := \{ z \in S^{d-1} : z = \frac{x}{\|x\|_2} \text{ for some } x \in C(2C_1n) \text{ with } \langle x, u \rangle \geq n\lambda(u)/2, \|z - \frac{w}{\|w\|_2}\| \geq \varepsilon \} \]
is independent of \( n \) and is covered by finitely many neighborhoods \( U_1, \ldots, U_N \) of the form \( U_i = \{ z \in S^{d-1} : \|z - v_i\| < \delta(v_i) \} \) with \( v_i \in S^{d-1} \). Thus, by (5.12), \( P\{x_n/\|x_n\|_2 \in W(\varepsilon) \text{ i.o.}\} = 0 \). This holds for all \( \varepsilon > 0 \). In view of (5.6) and (5.10), this implies
\[ P\left\{ \frac{x_n}{\|x_n\|_2} \to \frac{w}{\|w\|_2} \right\} = 1. \] (5.16)
In turn, this together with (5.6) implies
\[ \lim_{n \to \infty} \frac{n\lambda(u)}{\|x_n\|_2} = \lim_{n \to \infty} \frac{\langle x_n, u \rangle}{\|x_n\|_2} = \frac{\langle w, u \rangle}{\|w\|_2} \text{ a.s.} \]
Since \( \langle w, u \rangle \neq 0 \) (see (5.15)), \( \|x_n\|_2 \sim n\|w\|_2 \lambda(u)/\langle w, u \rangle \) and
\[ \lim_{n \to \infty} \frac{1}{n} x_n = \frac{\lambda(u)}{\langle w, u \rangle} w \text{ a.s.} \] (5.17)

To complete the proof of (5.8) we show that
\[ \lambda(u) = \langle w, u \rangle. \] (5.18)
Indeed, we already saw that \( \langle \tilde{x}_n, u \rangle = b/\|a\|_2 = \langle w, u \rangle \). We also saw that \( x_n = \gamma_n \tilde{x}_n \) with \( \gamma_n \sim n \). Therefore \( \langle x_n/n, u \rangle \sim \langle \tilde{x}_n, u \rangle = \langle w, u \rangle \). On the other hand, (5.17) implies that \( \lim_{n \to \infty} \langle x_n/n, u \rangle = \lambda(u) \). Thus (5.18) and (5.8) hold.
We now also obtain (5.5). Indeed, essentially the same argument as for (5.16), but now using (5.13) instead of (5.12) gives

\[ \sum_{k=0}^{\infty} P \left\{ \| x_{nk} \|_2 - \frac{w}{\|w\|_2} > \delta \right\} < \infty. \]  

(5.19)

Consequently also

\[ \sum_{k=0}^{\infty} P \{ \left| \frac{1}{n_k} (x_{nk}, u) - \frac{x_{nk}}{n_k} \langle w, u \rangle \right| > \frac{\delta \sqrt{d}}{n_k} \| x_{nk} \|_2 \} < \infty. \]

Together with (5.7), (5.18) and (5.11) this last relation yields

\[ \sum_{k=0}^{\infty} P \{ |\lambda(u) - \langle x_{nk} \|_2 \|w\|_2 \lambda(u) \rangle | > \delta 3C_1 d \} < \infty. \]

Thus, for a suitable constant \( K_7 \)

\[ \sum_{k=0}^{\infty} P \left\{ \left\| \frac{x_{nk}}{n_k} - \|w\|_2 \right\| > K_7 \delta \right\} < \infty. \]

Together with (5.19) this finally gives for some other constant \( K_8 \)

\[ \sum_{k=0}^{\infty} \left[ 1 - P \{ O_{n_k}(\eta)(w, K_8 \delta) \} \right] \]

\[ \leq \sum_{k=0}^{\infty} P \{ \| x_{nk} \|_2 - \|w\|_2 > K_8 \delta \} < \infty. \]

Since this holds for any \( \delta > 0 \), this is equivalent to (5.5).

The preceding (see (5.8)) shows that there exists a sequence \( \varepsilon_n \to 0 \), and random vertices \( x_n \) such that with probability 1, for all large \( n \),

\[ x_n \in nw + C(\varepsilon_n n) \text{ and } B^f(x_n, n) \text{ occurs,} \]

(5.20)

where

\[ B^f(x, s) := \{ \text{there is } B\text{-particle at } x \text{ at time } s \text{ in } P^f \}. \]

Now take

\[ \tilde{n} := n \left( 1 + \frac{8\varepsilon_n}{C_2} \right) \]

and define the event

\[ \mathcal{R}(x, n) = \{ \text{there is some particle in } P^f \text{ which lies in } x + C(C_2(\tilde{n} - n)/2) \]

\[ = x + C(4\varepsilon_n n) \text{ but is of type } A \text{ at time } \tilde{n} \}. \]
We shall complete the proof by proving that the event
\[
\{ \text{for infinitely many } n \text{ there exists an } x_n \text{ for which} \ \mathcal{B}^f(x_n, n) \cap \mathcal{R}(x_n, n) \text{ occurs}\} \tag{5.21}
\]
has probability 0. First we show that this will indeed prove the lemma. The probability that any particle which is in \(nw + \mathcal{C}(\varepsilon_n n)\) at time \(n\) is outside \(nw + \mathcal{C}(2\varepsilon_n n)\) at time \(\tilde{n}\) is bounded by
\[
K_9[\varepsilon_n n]^d P\{ \sup_{r \leq \tilde{n} - n} \|S_r\| \geq \varepsilon_n n \}. \tag{5.22}
\]
Without loss of generality we can let \(\varepsilon_n\) go to 0 so slowly that for large \(n\) this expression is no more than \(n^{-1} - K^{-1}\) (by (2.42) in [KSa]) and such that
\[
\varepsilon_n \geq n^{-1/2}. \tag{5.23}
\]
From this and the fact that \(\mathcal{B}^f(x_n, n)\) occurs for all large \(n\), we conclude via the Borel-Cantelli lemma that almost surely, for all large \(n\) there are particles in \(\mathcal{P}^f\) in the set \(nw + \mathcal{C}(2\varepsilon_n n)\) at time \(\tilde{n}\). The fact that (5.21) has probability 0 will then imply that \(\mathcal{R}(x_n, n)\) must fail for all large \(n\). But this implies that a.s. there are particles in \(\mathcal{P}^f\) which lie in \(nw + \mathcal{C}(2\varepsilon_n n)\subset x_n + \mathcal{C}(4\varepsilon_n n)\) at time \(\tilde{n}\), and all of these particles must have type \(B\). This is the desired result (5.3).

It remains to prove (5.21). But this is almost immediate from Proposition 1. Indeed,
\[
P\{\mathcal{B}^f(x_n, n) \cap \mathcal{R}(x_n, n)\}
\leq P\{x_n \notin \mathcal{C}(2C_1 n)\} + \sum_{x \in \mathcal{C}(2C_1 n)} P\{\mathcal{B}^f(x, n) \text{ but there is a particle in } \mathcal{P}^f \text{ of type } A \text{ at some } z \in x + \mathcal{C}(4\varepsilon_n n) \text{ at time } \tilde{n}\}
\leq K_6 n^{-K-d-1} + \sum_{x \in \mathcal{C}(2C_1 n)} P\{x \text{ is occupied at time } n \text{ in } \mathcal{P}^f \text{ and in the full-space process started at } (x, n) \text{ there is an } A\text{-particle at some } z \in x + \mathcal{C}(4\varepsilon_n n) \text{ at time } \tilde{n}\},
\]
where we used Lemma C for the last inequality. As in the estimate for \(K_2\) in (3.77), by (3.9) and (2.4) with \(K\) replaced by \(2K + 2d\), the last sum here is at most
\[
K_{10} n^d(\text{left hand side of (2.4) with } t = \tilde{n} - n = 8\varepsilon_n n/C_2) \leq K_{11} n^{-K}
\]
(see (5.23)).

The preceding lemma shows that the set \(B(t)\) grows in the direction of the exposed points of \(B_0\) in \(\partial B_0\) at the “right” speed. More specifically, if \(w\) is such a point, then almost surely, for all large \(t\), there exist points \(w(t) \in (1/t)B(t)\) such
that \( w(t) \to w \). We merely have to choose \( n \) in Lemma 9 such that \( n(1+8\varepsilon_n/C_2) \leq t \) but \( n/t \to 1 \), and then \( w(t) \) a point in \( \tilde{B}(n) \cap [nw+C(2\varepsilon_n n)] \). Lemma 9 guarantees that this last intersection is nonempty for large \( n \). The next two lemmas will show that the same is true for any point \( w \in \partial B_0 \). This is basically done by concatenating a number of paths which produce \( B \)-particles at \( \alpha_i n w_{n,i} \) for exposed points \( w_{n,i} \) and \( \sum_{i=1}^{k} \alpha_i w_{n,i} \to w, \alpha_i \geq 0, \sum_{i=1}^{k} \alpha_i = 1 \). Lemma 10 contains the basic technical step. It explains how the concatenation works; this is basically the same construction as in the proof of Lemma 7.

**Lemma 10.** Let \( w_1, w_2 \in \partial B_0 \). Assume that there exist \( \varepsilon_n > 0 \) such that \( \varepsilon_n \to 0 \) and such that (5.3) holds with \( w \) replaced by \( w_1 \), that is,

\[
P\{N_n(w_1, \varepsilon_n) \text{ occurs for all large integers } n\} = 1.
\]  

(We are not assuming that \( w_1 \) is an exposed point of \( B_0 \).) In addition, assume that for all \( \delta, \eta > 0 \)

\[
\sum_{k=0}^{\infty} \left[ 1 - P\{\mathcal{O}_{n_k(\eta)}(w_2, \delta)\} \right] < \infty
\]  

(see Corollary 5 for \( n_k = n_k(\eta) \)). Let \( 0 < \alpha < 1 \) and \( \eta > 0 \). Then there exist \( \delta_n > 0 \) such that \( \delta_n \to 0 \) and such that

\[
P\{N_n(\alpha w_1 + (1-\alpha)w_2, \delta_n) \text{ occurs for all large } n\} = 1.
\]  

**Proof.** Fix \( 0 < \alpha < 1 \). Also fix

\[
\delta > 0 \text{ and } 0 < \eta < \delta/2
\]

for the time being. Take

\[
p_k = p_k(\eta) = \left[ \frac{\alpha}{1-\alpha n_k(\eta)} \right]
\]

and

\[
q_k = q_k(\eta) = (1 + 8\varepsilon_{p_k(\eta)} C_2) p_k.
\]

Define \( \mathcal{O}_{n_k}'(w_2, \delta) \) as the translate by \( (p_k(\eta)w_1, q_k(\eta)) \) (in space-time) of \( \mathcal{O}_{n_k}(w_2, \delta) \).

Explicitly,

\[
\mathcal{O}_{n_k}'(w_2, \delta) = \{ \text{in the full-space process started at } (p_k(\eta)w_1, q_k(\eta)) \text{ there is at time } q_k + n_k \text{ a } B\text{-particle in } p_k w_1 + n_k w_2 + \mathcal{C}(\delta n_k) \}.
\]

(We suppress the dependence on \( w_1 \) and \( \eta \) in this notation). Also let

\[
z_k = \text{nearest occupied site to } p_k w_1 \text{ in } \mathcal{P}^I \text{ at time } q_k.
\]
Thus, on \( B \parallel \) as in (5.21) and in the lines following it we now have that almost surely
\[
\mathcal{O}_{n_k}^\prime (w_2, \delta) \text{ occurs for all large } k.
\] (5.27)
Also, by assumption (5.24), almost surely,
\[
\mathcal{N}_{p_k} (w_1, \varepsilon_{p_k}) \text{ occurs for all large } k.
\] (5.28)

Now consider a \( k \) for which \( \mathcal{N}_{p_k} (w_1, \varepsilon_{p_k}) \cap \mathcal{O}_{n_k}^\prime (w_2, \delta) \) occurs. By the definition of \( \mathcal{N}_{p_k} \) this implies that \( z_k \) lies in \( p_k w_1 + C(2 \varepsilon_{p_k} p_k) \) and that the particles at \( z_k \) at time \( q_k \) have type \( B \) in \( \mathcal{P}^f \). Therefore the resetting of the types to start the full-space process at \( (p_k w_1, q_k) \) does not change the type at \( z_k \). By the monotonicity property of Lemma C, \( \mathcal{P}^f \) therefore has at least as many \( B \)-particles at any space-time point \( (x, t) \) with \( t \geq q_k \) as the full state process started at \( (p_k w_1, q_k) \). Since \( \mathcal{O}_{n_k}^\prime (w_2, \delta) \) occurs this implies that in \( \mathcal{P}^f \) there is a \( B \)-particle in \( p_k w_1 + n_k w_2 + C(\delta n_k) \) at time \( q_k + n_k \).

Let the nearest \( B \)-particle to \( p_k w_1 + n_k w_2 \) in \( \mathcal{P}^f \) at time \( q_k + n_k \) be at the position \( y_k \), so that \( B^f (y_k, q_k + n_k, n_k) \) occurs. The last paragraph gives us that \( \| y_k - p_k w_1 - n_k w_2 \| \leq \delta n_k \). These are only statements for the times \( q_k + n_k \). Since (5.24) requires that certain events happen for all large \( n \) we now first show how to go from the \( q_k + n_k \) to general integers \( n \). For any large \( n \) let \( k(n) \) be such that \( q_k + n_k \leq n < q_{k+1} + n_{k+1} \). Then for large \( n \)
\[
q_k + n_k \leq n \leq (q_k + n_k)(1 + 2 \eta) \leq (q_k + n_k)(1 + \delta),
\]

since \( n_{k+1}/n_k \leq 1 + \eta \). Also by our choice of \( p_k, q_k \)
\[
\| p_k w_1 + n_k w_2 - n[\alpha w_1 + (1 - \alpha) w_2] \| \leq K_{12} \delta n.
\]

Thus, on \( B^f (y_k, q_k + n_k) \), there is a \( B \)-particle at \( y_k \in n[\alpha w_1 + (1 - \alpha) w_2] + C((K_{12} + 1) \delta n) \) at time \( q_k + n_k \). Moreover, as in (5.22) we have
\[
P \{ \text{in } \mathcal{P}^f \text{ there is a } B \text{-particle in } n[\alpha w_1 + (1 - \alpha) w_2] + C((K_{12} + 1) \delta n) \}
\]
\[
\text{at time } q_k + n_k \text{ which is no longer in } n[\alpha w_1 + (1 - \alpha) w_2] + C((K_{12} + 2) \delta n) \]
\[
\text{at time } n \}
\]
\[
= O(n^{-K}).
\]

Thus, almost surely, there is in \( \mathcal{P}^f \) for all large \( n \) a \( B \)-particle in \( n[\alpha w_1 + (1 - \alpha) w_2] + C((K_{12} + 2) \delta n) \) at time \( n \). We can now proceed as in Lemma 9. Essentially as in (5.21) and in the lines following it we now have that almost surely
\[
\{ \text{there is some } y \in n[\alpha w_1 + (1 - \alpha) w_2] + C((K_{12} + 2) \delta n) \text{ for which } \}
\]
\[
B^f (y, n) \text{ occurs, but in } \mathcal{P}^f \text{ there are either no particles or an } A \text{-particle in } \}
\]
\[
n[\alpha w_1 + (1 - \alpha) w_2] + C(2(K_{12} + 2) \delta) \text{ at time } (1 + 8(K_{12} + 2) \delta/C_2)n \}
\]
(5.29)
occurs only for finitely many \( n \). This shows that

\[
P\{ \mathcal{N}_n(\alpha w_1 + (1 - \alpha)w_2, (K_{12} + 2)\delta) \text{ occurs for all large } n \} = 1. \tag{5.30}
\]

This holds for all \( \delta > 0 \) and \( \eta < \delta/2 \). However, (5.30) is already independent of \( \eta \), so that it holds for all \( \delta > 0 \). There then also exists a sequence \( \delta_n \to 0 \) such that \( \mathcal{N}_n(\alpha w_1 + (1 - \alpha)w_2, \delta_n) \) occurs almost surely for all large \( n \).

**Proof of Theorem 1.** We shall prove (1.3) with the \( B_0 \) defined in (5.1). For the right hand inclusion in (1.3) we note that for any \( \varepsilon > 0 \) there exists finitely many halfspaces \( \{ z \in \mathbb{R}^d : \langle z, u_i \rangle \leq \lambda(u_i) \}, \ 1 \leq i \leq N \), with \( u_i \in S^{d-1} \) such that

\[
\cap_{i=1}^{N} \{ z \in \mathbb{R}^d : \langle z, u_i \rangle \leq \lambda(u_i) \} \subset (1 + \varepsilon/3)B_0. \tag{5.31}
\]

Indeed, \( B_0 \) is contained in the cube \( \tilde{C} := \cap_{i=1}^{N} \{ z \in \mathbb{R}^d : -\lambda(e_i) \leq \langle z, e_i \rangle \leq \lambda(e_i) \} \) (with \( e_i \) = \( i \)-th coordinate vector), and by compactness, \( \tilde{C} \setminus \text{interior of} \ (1 + \varepsilon/3)B_0 \) is covered by finitely many relatively open subsets of \( \tilde{C} \) of the form \( \tilde{C} \cap \{ z \in \mathbb{R}^d : \langle z, u \rangle > \lambda(u) \} \). In addition to (5.31) we know from (4.35) that, almost surely, \( H(t, u_i) < t(1 + \varepsilon/3)\lambda(u_i) \) for all large \( t \) and \( i = 1, \ldots, N \). Consequently, almost surely

\[
\tilde{B}(t) \subset t(1 + \varepsilon/3)\cap_{i=1}^{N} \{ z \in \mathbb{R}^d : \langle z, u_i \rangle \leq \lambda(u_i) \} \subset (1 + \varepsilon/3)^2tB_0
\]

for all large \( t \). Thus the right hand inclusion in (1.3) holds.

For the left hand inclusion in (1.3) we first observe that by Lemma 9, the hypotheses (5.24) and (5.25) of Lemma 10 hold for all exposed points \( w_1, w_2 \in \partial B_0 \). It then follows from Lemma 10 that (5.26) holds. In turn, (5.26) states that the hypothesis (5.24) with \( w_1 \) replaced by \( \alpha w_1 + (1 - \alpha)w_2 \) is satisfied. Therefore, if \( w_3 \in \partial B_0 \) is also an exposed point of \( B_0 \) and \( 0 < \beta < 1 \), then we get from Lemma 10 that there exist \( \delta_n' \to 0 \) such that

\[
P\{ \mathcal{N}_n(\beta \alpha w_1 + \beta(1 - \alpha)w_2 + (1 - \beta)w_3, \delta'_n) \text{ occurs for all large } n \} = 1.
\]

But as \( \alpha \) and \( \beta \) vary over \( (0, 1) \), \( \beta \alpha w_1 + \beta(1 - \alpha)w_2 + (1 - \beta)w_3 \) varies over the convex combinations \( \alpha_1 w_1 + \alpha_2 w_2 + \alpha_3 w_3 \) with \( \alpha_i > 0, \sum_{i=1}^{3} \alpha_i = 1 \). We can repeat this procedure to obtain that for each convex combination \( \sum_{i=1}^{k} \alpha_i w_i \) with \( \alpha_i \geq 0, \sum_{i=1}^{k} \alpha_i = 1 \) and \( w_i \in \partial B_0 \) exposed points of \( B_0 \), there exist \( \delta_n \to 0 \) such that

\[
P\{ \mathcal{N}_n(\sum_{i=1}^{k} \alpha_i w_i, \delta_n) \text{ for all large integers } n \} = 1.
\]
In particular (see (5.4)), for each such $\sum_{i=1}^{k} \alpha_i w_i$ and each fixed $\eta > 0$

$$P\{\text{in } \mathcal{P}^f \text{ there are at time } (1 + 8\delta_n/C_2)n \text{ B-particles in}$$
$$n \sum_{i=1}^{k} \alpha_i w_i + C(2\eta n) \text{ for all large integers } n\} = 1.$$  

In turn, this means that if for a given vector $v$ and $\eta > 0$ we can find $\alpha_i, w_i$ as above such that $\|v - \sum_{i=1}^{k} \alpha_i w_i\| \leq \eta$, then also

$$P\{\text{in } \mathcal{P}^f \text{ there are at time } (1 + 8\delta_n/C_2)n \text{ B-particles in}$$
$$nv + C(3\eta n) \text{ for all large integers } n\} = 1. \quad (5.32)$$

If $v$ is such that there exist $k^{(r)} < \infty, \alpha_i^{(r)} \geq 0$ and $w_i^{(r)} \in \partial B_0$ exposed points of $B_0$ such that $\sum_{i=1}^{k^{(r)}} \alpha_i = 1$ and $\|v - \sum_{i=1}^{k^{(r)}} \alpha_i^{(r)} w_i^{(r)}\| \to 0$ (as $r \to \infty$), then (5.32) holds for each $\eta > 0$. For such $v$ there then exist $\eta_n \to 0$ such that almost surely, for all large $n$ there exist $B$-particles within distance $4\eta_n n$ of $nv$ at time $(1 + 8\delta_n/C_2)n$, for some $\delta_n \to 0$ ($\delta_n$ and $\eta_n$ may depend on $v$).

The last statement applies to each $v \in B_0$, because each such $v$ is a convex combination of at most $(d + 1)$ extreme points of $B_0$ (see [Ru], Theorem 3.22 and Lemma following Theorem 3.25) and the exposed points of $B_0$ are dense in the extreme points (Strascewicz’ theorem; see Theorem 18.6 in [Ro]). Thus, by applying the last result to a fixed $v \in B_0$ with $n = \lfloor(1 - \varepsilon)t\rfloor$ and $0 < \varepsilon < 1$, we find that almost surely for all large $t$,

at time $(1 + 8\delta_n/C_2)n$ there exists a site $v_n$ with

$$\|v_n - nv\| \leq 4\eta_n n,$$  

which is occupied in $\mathcal{P}^f$ by $B$-particles.  

We claim that

$$P\{(5.33) \text{ holds, but not all sites in } (1 - \varepsilon)t v + C(C_2\varepsilon t/4) \text{ belong to } \tilde{B}(t)\} \leq K_{13} t^{-K}. \quad (5.34)$$

This is an easy consequence of (3.9) and Theorem A. Indeed, from (3.9) with $(X, s)$ taken to be $(v_n, (1 + 8\delta_n/C_2)n)$ and

$$\mathcal{A} = \{\text{not all vertices in } C(C_2\varepsilon n/2) \text{ have been visited by a } B\text{-particle by time } \varepsilon n/2\}$$

$$= \{C(C_2\varepsilon n/2) \not\subset B(\varepsilon n/2)\},$$

we see that the probability in (5.34) is for large $t$ at most

$$K_{14} n^d P_{\text{or}}\{C(C_2\varepsilon n/2) \not\subset B(\varepsilon n/2)\} \leq K_{15} n^{-K} \leq K_{13} t^{-K}$$

(for the first inequality here we used Theorem A with $K + d$ in the place of $K$). This establishes the claim (5.34).
To obtain Theorem 1 we now choose for a given \( \varepsilon \) a finite number of vectors \( v^{(1)}, \ldots, v^{(N)} \) in \( B_0 \) such that each \( v \in B_0 \) satisfies \( \|v - v^{(r)}\| < C_2 \varepsilon /4 \) for at least one \( r \). This means that

\[
B_0 \subset \bigcup_{1 \leq r \leq N} \left[ v^{(r)} + C(C_2 \varepsilon /4) \right].
\]

Moreover, by (5.33) and (5.34) it holds almost surely for all large \( t \) that

\[
\bigcup_{1 \leq r \leq N} \left[ (1 - \varepsilon)tv^{(r)} + C(C_2 \varepsilon t /4) \right] \subset \tilde{B}(t).
\]

Together, these last two inclusions imply that almost surely the left hand inclusion in (1.3) holds for all large \( t \).
