Electrocatalytic oxidation
Multi-wall carbon nanotubes
Uric acid
Folic acid

Abstract

Uric acid (UA) and folic acid (FA) are compounds of biomedical interest. In humans, about 70% of daily uric acid disposal occurs via the kidneys, and in 5–25% of humans, impaired renal (kidney) excretion leads to hyperuricemia. Folate is another form folic acid of which is known as, is one of the B vitamins. It is used as a supplement by women to prevent neural tube defects developing during pregnancy. Poly ortho-methoxyaniline nanostructures (POMANS) was synthesized with a new two phase (organic-water) synthesis method. The POMANS was characterized using transmission electron microscopy (TEM) and Fourier transform IR (FTIR). This polymer was used to construct a modified multi-wall carbon nanotube, graphite paste electrode (POMANS-MWCNT/GPE). Linear sweep voltammograms (LSV), cyclic voltammetry (CV) and chronoamperometry were used to investigate the suitability of poly ortho-methoxyaniline with multi-wall carbon nanotubes paste electrode as a modifier for the electrocatalytic oxidation of UA and FA in aqueous solutions with various pHs. The results showed that POMANS-MWCNT/GPE had high anodic peak currents for the electrooxidation of UA and FA in pH 6.0. Under the optimized conditions, The catalytic peak currents obtained, was linearly dependent on the UA and FA concentrations in the range of 0.6–52 and 0.5–68 μM with two segments and the detection limits 0.157 and 0.113 μM for UA and FA were, respectively. Finally, the proposed method was also examined as a sensitive, simple and inexpensive electrochemical sensor for the simultaneous determination of UA and FA in real samples such as urine and serum.

1. Introduction

Conducting polymers (CPs) such as polyaniline, polypyrrole, polythiophene and their derivatives, has been used as modifier in electrochemical sensors, catalysts and electro chromic materials and many more, etc. [1–5]. Among different CPs, poly ortho-methoxyaniline (POMA), has been one of the most extensively studied polymers in fabrication of the sensor devices, because POMA has useful features including high electrical conductivity, good environmental stability, electrochemical redox activity even in neutral pH solutions [6–9]. To increase the surface area of catalysis, enhance catalytic activity and sensitivity due to the increase of surface, POMA has been supported by different material [10,11].

Uric acid (2,6,8-trihydroxypurine) (UA) the end metabolic product of purine through the liver, is present in blood and urine. Abnormal UA level in a human body could be caused by several diseases such as gout, hyperuricemia, Lesch–Nyan syndrome, as well as cardiovascular and chronic renal diseases. Hence, monitoring of the concentration of UA in biological fluids may be used as an early warning of the presence of these diseases. Electrochemical sensors for the determination of UA are simple, rapid, inexpensive and easy to use [12–16]. Folic acid, ((25)-2-{[4-[[2-amino-4-hydroxypteridin-6yl]methyl][amino][phenyl] formamido] pentanedioic acid), also known as vitamin B₉, vitamin M and folacin, is a form of the water-soluble vitamin B₉. FA deficiency causes failure to make the purines and thymine required for DNA synthesis. FA is necessary for cell development, for metabolism of specific biochemical reactions in the body and the metabolism of specific anticonvulsant drugs [17–19]. Since, UA and FA always co-exist in the human body fluids, So, it has essential for the simultaneous determination of UA and FA.

Carbon nanotubes (CNTs, includes multi-wall carbon nanotubes and single-wall carbon nanotubes), the new forms of elementary carbon, are composed of graphic sheets rolled into close concentric cylinders with diameter of nanometers and length of micrometers. Because of the special tube structure, CNTs possess several unique properties such as good electrical conductivity, high chemical stability, and extremely high mechanical strength [20]. The better performance of the CNTs electrode compared to other electrodes may be due to the carbon nanotube dimensions, the electronic structure, and the topologic
defects present on the tube surface [21,22]. Problems of low catalytic performance for analysis of toxic and biologic compounds with CNTs, nano composites and its hybrids are improved [23,24]. It has been reported that carbon nanotube-modified electrodes were successfully applied to study and determine many biological compounds, drugs and toxic materials [25–28].

To our knowledge, there are no similar studies on the polymerization of poly ortho-methoxyaniline nanostructures (POMANS) and its application as novel modifier in modified graphite paste electrode including MWCNTs for the simultaneous determination of uric acid and folic acid in aqueous solution. The present work describes the synthesis of POMA with a new two phase (organic-water) method. The electrochemistry behavior of POMANS-MWCNTs/GPE and investigation of its electrocatalytic effect on simultaneous determination of UA and FA was studied in details. It was found that the POMANS-MWCNTs/GPE showed an electrocatalytic activity towards the oxidation of UA and FA by enhancing its oxidation currents when compared to bare GPE and MWCNTs/GPE. Finally, in order to demonstrate the catalytic ability of the modified electrode in the determination of UA and FA in real samples, we examined this method for the voltammetric simultaneous determination of UA and FA in samples of serum and urine.

2. Experimental

2.1. Chemicals

Isobutyl methyl ketone (4-methyl-2-pentanone), potassium persulfate (K₂S₂O₈), phosphoric acid, hydrochloric acid and sodium hydroxide with analytical grade were obtained from Merck company. Uric acid, folic acid, multi-wall carbon nanotubes, with nanotube diameters, OD = 20–30 nm, wall thickness = 1–2 nm, length = 0.5–2 μm and purity >95%, graphite powder and high-viscosity paraffin oil were purchased from Aldrich. Ortho-methoxyaniline (OMA) was prepared from Aldrich and was purified immediately prior to use by passing small aliquots through an activated alumina column. All solutions were freshly prepared by doubly distilled water (DDW), purged with pure nitrogen gas (99.999%) before investigations.

2.2. Instrumentation

All electrochemical experiments were performed using a SAMA 500 Electroanalyser (SAMA Research Center, Iran) controlled by a personal computer. A platinum wire was used as the auxiliary electrode. A saturated calomel electrode (SCE) and POMANS-MWCNTs/GPE were used...
as the reference and working electrodes, respectively. A pH-meter (Metrohm 744 pH/ion meter) was used to read the pH of the buffered solutions. The FTIR spectra were measured in transmission mode using Valor III (JASCO) equipped with a MCT detector. TEM images were taken using a Philips CM120 transmission electron microscopy with 2.5 Å resolution.

2.3. Synthesis of poly ortho-methoxyaniline nano structures

In order to synthesis of poly ortho-methoxyaniline nano structures, we prepared two separate solutions in organic phase and aqueous phase; for organic phase, 1.5 mL of OMA (after the purified with activated alumina column) was added to 10mL isobutyl methyl ketone at acidic media (0.1 ml HCl as catalyzer) and the aqueous phase, 5.0 g of potassium persulfate in 50 mL of doubly distilled water was dissolved. Next, provided organic phase was added to aqueous phase and was placed in ultrasonic agitation for 2 h. The mixed solution was stirred by magnetic stirring apparatus at room temperature for 3 h. Then, by a decanter was separated aqueous phase from organic phase and dried at vacuum oven at 60 °C for 2 h for fling solvent, then prepared polymer was washed doubly distilled water and was dried at room temperature.

2.4. Preparation of the electrode

In the other to obtain the best conditions in the preparation of the POMANS-MWCNTs/GPE, we optimized the ratio of POMANS, MWCNTs and graphite powder. The POMANS-MWCNTs/GPE was prepared by hand-mixing of 0.80 g of graphite powder, 0.15 g POMANS and 0.05 g MWCNTs plus paraffin (~0.8 mL) and mixed well for 30 min until a uniformly wetted paste was obtained. This paste was then packed into the end of a glass tube. A copper wire inserted into the carbon paste provided an electrical contact. When necessary, a new surface was obtained by pushing an excess of paste out of the tube and polishing with weighing paper. For comparison, a modified CPE (MWCNTs/GPE) without POMANS and an unmodified GPE without both POMANS and MWCNTs were also prepared in the same method.

3. Results and discussion

3.1. Characterization of poly ortho-methoxyaniline nano structures

The morphology of poly ortho-methoxyaniline nano structures was characterized by transmission electron microscopy and Fourier transform IR. As can be seen in Fig. 1A, the POMANS film shows homogeneity.
morphology with the formation of aggregates. The aggregate size is in the range of several decades of nanometers. MWCNTs can be seen on the surface of GPE as is shown in Fig. 1B. Also, in addition to MWCNTs, nano structures from POMA at the surface of electrode are covered with graphite sheets mixed with aggregates of carbon particles (Fig. 1B). In this case a massive and packed layer has covered the electrode surface in a way that blocked the interlayer diffusion of the analyte species through the film. FTIR spectroscopy (Fig. 1C) evidences for presence of $\text{N-H}$, $\text{C-O}$, $\text{C=O}$ at 1658.7 cm$^{-1}$, corresponds to $\text{C-O}$ group at 1433.0 & 1413.7 cm$^{-1}$, $\text{O-C=O}$ in plane deformation at 954.7 cm$^{-1}$, $\text{C-C}$ in plane deformation at 613.3 cm$^{-1}$, stretching vibrations in quinoid-ring at 1658.7 cm$^{-1}$ and Stretching vibrations of benzoid-ring at 1433.0 cm$^{-1}$ [29].

### 3.2. Electrochemical behavior of UA and FA on POMANS-MWCNT/GPE

Cyclic voltammetry studies using three different electrodes, GPE, MWCNT/GPE, and POMANS-MWCNT/GPE, in buffered solution (blank) showed that in the entire potential range, no considerable peak can be seen (Fig. 2). Fig. 2B cyclic voltammograms were recorded for 0.1 mM UA and 0.15 mM FA at surface of noticed electrodes. As can be seen a small anodic peak currents for UA and FA at GPE, with added MWCNTs to GPE was seen (curve b’ in Fig. 2B) significantly increased the anodic peak currents compared with the GPE. However, it is obvious that the POMANS-MWCNT/GPE exhibits enhanced electrocatalytic oxidation with higher peak currents for the oxidation of UA and FA in comparison to the GPE and MWCNT/GPE (curve c’ in Fig. 2B). The combination of POMANS and MWCNTs improved the electronic transport capacity and made the electron transfer easier between species and electrode.

### 3.3. Influence of solution pH

The voltammetric investigations were performed in the pH range of 4.0–8.0 using 0.1 M phosphate buffer solution (PBS) as supporting electrolyte, containing 25 μM UA and 50 μM FA at scan rate 20 mV s$^{-1}$ (Fig. 3a). As can be seen in Fig. 3b & c, the anodic peak potential shows a negative shift by increasing the solution pH with a slope value of 45.0 mV and 59.0 mV per pH unit for UA and FA, respectively (near to the theoretical slope, 59 mV per pH unit). From the results, it can be concluded that equal numbers of electrons and protons are involved in the electro-oxidation of UA and FA on the surface of the POMANS-MWCNT/GPE [13,18]. The anodic peak currents of UA and FA reach their maximum values at pH 6.0 (Fig. 3b & c). Therefore, all voltammetric determinations have been performed in a phosphate buffer solution of pH 6.0, as the optimum pH.
Fig. 5. (a) Chronocoulograms obtained at POMANS-MWCNT/GPE in 0.1 M PBS (pH 6.0) for different concentrations of UA. The numbers 1–5 correspond to 0, 0.07, 0.11, 0.14, and 0.18 of UA. (b) Plots of Q vs. t\(^{1/2}\) obtained from chronoamperograms 2–5. (c) Plot of the slope of the straight lines against UA concentration. Similarly, chronocoulometric response of the modified POMA/MWCNT/GPE in 0.1 M phosphate buffer solution (pH 6.0) at potential step of 0.75 V for different concentrations of FA (a'). The letters 1–4 correspond to 0, 0.05, 0.13 and 0.19 mM FA. (b') Plots of Q versus t\(^{1/2}\) obtained from the chronocoulograms and (c') plot of the straight lines against the FA concentration.

Fig. 6. (a) Linear sweep voltammograms of POMANS-MWCNT/GPE 0.1 mol/L PBS (pH 6.0) containing different concentrations of UA and FA. The numbers 1–25 correspond to 0, 0.6, 0.9, 1.2, 1.5, 1.8, 2.1, 2.4, 2.7, 3, 3.3, 3.6, 4, 8, 12, 16, 20, 24, 28, 32, 36, 40, 44, 48 and 52 μM of UA and 0, 0.5, 0.75, 1, 1.25, 1.5, 1.75, 2, 2.25, 2.5, 2.75, 3, 8, 13, 18, 23, 28, 33, 38, 43, 48, 53, 58, 63 and 68 μM of FA. (b) Represents the variations of anodic peak currents vs. uric acid concentration. (c) Represents the variations of anodic peak currents vs. folic acid concentration.
3.4. Effect of scan rate

The effect of scan rate on the electrocatalytic oxidation of 0.25 mM of UA and 0.45 mM of FA at the POMANS-MWCNT/GPE was investigated by cyclic voltammetry (Fig. 4a). The anodic peak potentials shift towards a more positive potential with increasing scan rates, confirming the kinetic limitation of the electrochemical reaction. The anodic peak currents (Ipa) for UA and FA increased linearly with the square root (√ν) of the scan rate of potentials (Fig. 4b), suggesting that a sufficient over potential the reaction is diffusion limited. A Tafel plot is also a useful device for evaluating kinetic parameters [30].

\[ I_p = 3.01 \times 10^5 n(1-\alpha)n_{a1}^{1/2}AC_0D^{1/2} \sqrt{\nu} \]  

(1)

According to Eq. (1) and slopes of Fig. 4b the total number of electrons involved in the anodic oxidations for UA and FA were 1.93 and 2.05, respectively.

3.5. Chronocoulometric studies

The chronocoulometry as well as the other electrochemical methods was also employed for the investigation of electrode processes at chemically modified electrodes. Chronocoulometric studies of UA at POMANS-MWCNT/GPE were done by setting the working electrode potential at 350 mV for various concentrations of UA (Fig. 5a). For an electroactive material of UA with a diffusion coefficient of D, the current for the electrochemical reaction, with a mass transport limited rate, is described by the Cottrell equation [30]. Under diffusion control, a plot of Q versus t^{1/2} will be linear (Fig. 5b), and from the slope versus concentration (Fig. 5c) the value of D can be obtained. The value of the D for UA was found to be 2.76 × 10^{-5} cm² s⁻¹. Similarly, by setting the working electrode potential at 750 mV for FA and carried out the Steps, value of the D for FA was found to be 3.45 × 10^{-5} cm² s⁻¹ (Fig. 5a, b and c).

3.6. Calibration curve and limit of detection

The results of the voltammetric studies for various concentrations of UA and FA on the surface of POMANS-MWCNTs/GPE, which were obtained under the above mentioned optimum experimental conditions, are shown in Fig. 6a. The oxidation currents of UA showed linear dependence with its concentration over two intervals in the ranges of 0.6 to 4.0 μM (Eq. (2)) and 4.0 to 52.0 μM (Eq. (3)):

\[ \Delta I_{pa} (\mu A) = 4.050 C_{UA} (\mu M) + 0.382 \quad (R^2 = 0.995) \]  

(2)

\[ \Delta I_{pa} (\mu A) = 0.398 C_{UA} (\mu M) + 13.730 \quad (R^2 = 0.996) \]  

(3)

Table 1

| Sample             | Spiked (μM) | Found (μM) | Recovery (μM) | RSD (%) |
|--------------------|-------------|------------|---------------|---------|
| Human urine        | UA          | FA         | UA            | FA      |
| 0                  | ND          | 10.3       | -             | -       | 2.7 |
| 5.0                | 3.0         | 15.1       | 2.9           | 98.7    | 96.7 | 2.1  | 2.4 |
| 10.0               | 5.0         | 20.7       | 4.8           | 102.0   | 96.0 | 1.9  | 2.7 |
| 15.0               | 10.0        | 24.9       | 10.3          | 98.4    | 103.0| 1.9  | 2.3 |
| 20.0               | 15.0        | 30.8       | 15.4          | 101.7   | 102.7| 1.6  | 2.5 |
| Human blood serum  | 0           | 5.4        | ND            | -       | -    | 3.6  | -   |
| 5.0                | 3.0         | 10.2       | 3.1           | 98.1    | 103.3| 1.7  | 2.1 |
| 10.0               | 5.0         | 15.7       | 5.2           | 101.9   | 104.0| 1.4  | 2.5 |
| 15.0               | 10.0        | 21.3       | 10.3          | 104.4   | 103.0| 1.8  | 2.9 |
| 20.0               | 15.0        | 26.3       | 14.7          | 103.5   | 98.0 | 2.6  | 2.8 |

RSD relative standard deviation, ND not detected.
The results for FA also showed two linear intervals in the ranges of 0.5 to 3.0 μM (Eq. (4)) and 3.0 to 68.0 μM (Eq. (5)):

$$\Delta A_{FA} (\mu V) = 5.621 C_{FA} (\mu M) + 1.483 \quad (R^2 = 0.994) \quad (4)$$

$$\Delta A_{FA} (\mu V) = 0.357 C_{FA} (\mu M) + 15.570 \quad (R^2 = 0.996) \quad (5)$$

The decreases of sensitivity (slope) in the second linear ranges are likely to be due to kinetic limitation. Detection limits (S/N = 3) are obtained as 0.157 μM (UA) and 0.113 μM (FA). The other performance this sensor, ability for simultaneous voltammetric detection of the trace amounts of UA and FA. Fig. 7a shows LSVs recording in various concentrations of FA (from 1 μM to 2.8 μM) in the presence of a constant concentration of 3 μM of UA. Fig. 7b shows LSVs of various UA concentrations (same as Fig. 7a for FA) in the presence of 2 μM of FA on the surface of POMANS-MWCNT/GPE.

3.7. Analytical applications

In order to evaluate the applicability of the proposed method, the modified electrode was used for simultaneous determination of the content of UA and FA in urine and serum by standard addition method. In order to avoid the interferences of the real samples, from real sample contents such as good reproducibility and repeatability, high sensitivity, wide linear dynamic range, low detection limit, acceptable longtime stability, the measurements to prevent the matrix effect of real samples. The preparation of the modified electrode with holmium fluoride nanorods/multi-walled carbon nanotube as a new biosensor, Sensors Actuators B 188 (2013) 65–72.

4. Conclusions

Poly ortho-methoxyaniline nanostructures were synthesized by a new method of two-phase and were used for fabrication of an electrochemical sensor for simultaneous determination of uric acid and folic acid. The obtained results revealed a considerable enhancement in the electrochemical performance of the modified electrode towards POMANS. The prepared electrode with desirable electrochemical features such as good reproducibility and repeatability, high sensitivity, wide linear dynamic range, low detection limit, acceptable longtime stability of the electrode response and low cost together with the easy preparation of the modified electrode. Finally, the nanostucture probe in modified electrode showed satisfactory results when applied for the determination of these substances in human urine and human blood serum as real samples.
