Abstract

This paper considers the problem of finite-time stability for stochastic nonlinear systems. A new Lyapunov theorem of stochastic finite-time stability is proposed, and an important corollary is obtained. Some comparisons with the existing results are given, and it shows that this new Lyapunov theorem not only is a generalization of classical stochastic finite-time theorem, but also reveals the important role of white-noise in finite-time stabilizing stochastic systems. In addition, multiple Lyapunov functions-based criteria on stochastic finite-time stability are presented, which further relax the constraint of the infinitesimal generator $LV$. Some examples are constructed to show significant features of the proposed theorems. Finally, simulation results are presented to demonstrate the theoretical analysis.

Key words: Finite-time stability; Generalized Lyapunov theorem; Multiple Lyapunov functions; Stochastic nonlinear systems.

1 Introduction

Stochastic stability has been one of the most fundamental research topics of controlled systems modeled by stochastic differential equation in the past few decades, and we here mention [11], [1], [7], [10], [4], [12], [13], [6] and [23] among others.

In classical stochastic stability theory, asymptotic stability in probability, $p$-order moment asymptotic stability, and almost sure asymptotic stability are often considered. These three types of stability describe the asymptotic behavior of the trajectories of a stochastic system as time goes to infinity. In many applications, however, it is desirable that a stochastic system possesses the property that its trajectories converge to a Lyapunov stable equilibrium state in finite time rather than merely asymptotically.

To develop the theory of finite-time stability of deterministic systems [2] to the stochastic case, the notions and Lyapunov criteria of stochastic finite-time stability were introduced separately in [18] and [3]. Based on the presented stochastic finite-time stability theory, finite-time stabilization controllers of stochastic nonlinear systems by state or output feedback are designed in [9], [19], [17] and [22] for example. Properties of finite-time stable stochastic systems are further discussed in [20]. Recently, finite-time stability of homogeneous stochastic nonlinear systems is studied in [21].

In those existing papers, the stochastic finite-time stability is required that the infinitesimal generator $LV$ satisfies $LV \leq -cV^\gamma$ with $0 < \gamma < 1$ and $c > 0$. So far, to the best of our knowledge, there are not any papers that could demonstrate whether the stochastic finite-time stability still holds or not, if this condition is not fulfilled.

In this paper, our target is to establish new Lyapunov criteria of stochastic finite-time stability under more general conditions. The main contributions of this paper are as follows: A new Lyapunov theorem on finite-time stability of stochastic nonlinear systems is proved, and an important corollary follows directly: By comparing the new Lyapunov theorem with the previous results of stochastic finite-time stability, it is shown that this gen-
eralized criterion not only relaxes the constraint on infinitesimal generator $LV$, but also reveals the important applications of white-noise in finite-time stabilizing a system; In addition, multiple Lyapunov functions-based criteria of stochastic finite-time stability are presented, which further relax the constraint of the infinitesimal generator $LV$; Some examples are constructed to show the significant features of our results.

The rest of the paper is organized as follows. The mathematical preliminaries are given in Section 2. A new Lyapunov theorem of stochastic finite-time stability is presented in Section 3. In Section 4, we derive an important corollary and discuss the comparisons with the existing results. In Section 5, multiple Lyapunov functions-based criteria of stochastic finite-time stability are presented. Section 6 gives some simulation results to illustrate the theoretical results. Finally, concluding remarks are given in Section 7.

Notations: $\mathbb{R}_+$ stands for the set of all nonnegative real numbers, $\mathbb{R}^n$ is the $n$-dimensional Euclidean space, $\mathbb{R}^{n \times m}$ is the space of real $n \times m$-matrices. $|x|$ is the usual Euclidean norm of a vector $x$. $A^T$ denotes the transpose of matrix $A$. $\text{Tr}\{A\}$ is its trace when $A$ is a square matrix. $C^2$ denotes the family of all functions with continuous second partial derivatives. A random variable $\xi \in L^1$ means that $E[\xi] < \infty$, $\mu : \mathbb{R}_+ \to \mathbb{R}_+$ is a $K_\infty$ class function means that it is continuous, strictly increasing, $\mu(0) = 0$ and $\lim_{s \to \infty} \mu(s) = \infty$. $a \wedge b = \min\{a, b\}$.

2 Preliminary results

In this paper, we consider a stochastic nonlinear system modeled by the following stochastic differential equation:

$$dx = f(x)dt + g(x)dB(t), \quad x(0) = x_0 \in \mathbb{R}^n, \quad (1)$$

where $x \in \mathbb{R}^n$ is the system state; $B(\cdot)$ is an $m$-dimensional standard Brownian motion defined on a complete probability space $(\Omega, \mathcal{F}, P)$; $f : \mathbb{R}^n \to \mathbb{R}^n$ and $g : \mathbb{R}^n \to \mathbb{R}^{n \times m}$ are continuous in $x$ and satisfying $f(0) = 0$ and $g(0) = 0$, which implies that (1) has a trivial zero solution.

As discussed in [21], in general, we are interested in having a unique solution in forward time for a stochastic differential equation. However, it is generally difficult to ensure such a property for a stochastic differential equation without locally Lipschitz continuous coefficients. Actually, it has been pointed out in [18], a finite-time stable stochastic nonlinear system does not have locally Lipschitz continuous coefficients. Hence, it suffices to require the existence of solutions for a stochastic nonlinear system either in the strong sense or in the weak sense when studying finite-time stochastic stability.

Remark 1: A weak solution to system (1) can be well-defined, and its precise definition can be found in ([15], p.149). In fact, a strong solution is of course also a weak solution. It is also pointed out in [15] that the concept of weak solutions is appropriate for control problems.

Let $LV$ denote infinitesimal generator of a $C^2$ function $V : \mathbb{R}^n \to \mathbb{R}$ along stochastic differential equation (1) with the definition of

$$LV(x) = \frac{\partial V(x)}{\partial x} f(x) + \frac{1}{2} \text{Tr} \left\{ g^T(x) \frac{\partial^2 V(x)}{\partial x^2} g(x) \right\}, \quad (2)$$

where $\frac{\partial V}{\partial x}$ denotes the gradient of $V$ (written as a row vector), and $\frac{\partial^2 V}{\partial x^2}$ denotes the Hessian of $V$.

The following lemma (see Lemma 2.1 of [19]) gives an existence result of a weak solution to system (1).

Lemma 1 [19]: Suppose that there exists a nonnegative $C^2$ function $V : \mathbb{R}^n \to \mathbb{R}_+$, which is radially unbounded, that is, $\lim_{|x| \to \infty} V(x) = \infty$. If the infinitesimal generator of $V$ with respect to (1) satisfies $LV(x) \leq 0$, then (1) has a regular continuous solution (in the weak sense) for any initial data.

A regular solution means that the solution has no finite explosion time with probability one. The detailed definition of regular solution can be founded in [7]. The next lemma is one of the well-known Doob’s Optional-Sampling Theorem for continuous nonnegative supermartingales, which can be found in ([16], p.189, (77.5)) and is useful in later analysis.

Lemma 2 [16]: Suppose that $X(t)$ is a continuous nonnegative supermartingale with respect to a filtration $\{\mathcal{F}_t\}_{t \geq 0}$. Let $S$ and $T$ be stopping times with $S \leq T$. Then $X(T) \in L^1$, and

$$E(X(T)|\mathcal{F}_S) \leq X(S). \quad (3)$$

3 Generalized stochastic finite-time stability theorem

In this section, we first review and refine the definition of stochastic finite-time stability introduced in [18,19]. Then a new Lyapunov theorem on finite-time stability of stochastic nonlinear systems will be given, and an important corollary is derived as well.

Definition 1: The trivial zero solution of (1) is said to be stochastically finite-time stable, if the stochastic system admits a solution (either in the strong sense or in the weak sense) for any initial data $x_0 \in \mathbb{R}^n$, and the following properties hold:

(i) Finite-time attractiveness in probability: For every
initial value \( x_0 \in \mathbb{R}^n \setminus \{0\} \), and any solution \( x(t; x_0) \), the first hitting time of \( x(t; x_0) \), i.e., \( \tau_{x_0} = \inf\{t \geq 0 : x(t; x_0) = 0\} \), called stochastic settling time, is finite almost surely, that is \( P(\tau_{x_0} < \infty) = 1 \); moreover,
\[
x(t + \tau_{x_0}; x_0) = 0, \quad \forall t \geq 0, \text{ a.s.} \quad (4)
\]

(ii) Stability in probability: For any solution \( x(t; x_0) \), and every pair of \( \varepsilon \in (0, 1) \) and \( r > 0 \), there exists a \( \delta(\varepsilon, r) > 0 \) such that
\[
P(\|x(t; x_0)\| < r \text{ for all } t > 0) \geq 1 - \varepsilon \quad (5)
\]
whenever \( |x_0| < \delta \).

**Remark 2:** The finite-time attractiveness in probability defined here states that any trajectories of a stochastic system will not only reach the origin in finite time, but also stay at the origin for ever after the stochastic settling time almost surely. So the origin is both an equilibrium point and an absorbing state.

**Remark 3:** The stability in probability is equivalent to that: For any solution \( x(t; x_0) \), and any \( r > 0 \),
\[
\lim_{t \to 0^+} P \left( \sup_{t \geq 0} |x(t; x_0)| \geq r \right) = 0 \quad (6)
\]
holds, which will be used in the following analysis.

Now, it is ready to state a new Lyapunov theorem on stochastic finite-time stability.

**Theorem 1:** For system (1), if there exists a \( C^2 \) positive definite and radially unbounded function \( V : \mathbb{R}^n \to \mathbb{R}_+ \), a positive constant \( c > 0 \), such that
\[
\mathcal{L}V(x) \leq 0, \quad \forall x \in \mathbb{R}^n, \quad (7)
\]
and
\[
K(V(x)) [cK(V(x)) + \mathcal{L}V(x)] \\
\leq \frac{K'(V(x))}{2} \left| \frac{\partial V}{\partial x} g(x) \right|^2, \quad \forall x \in \mathbb{R}^n \setminus \{0\}, \quad (8)
\]
where \( K : \mathbb{R}_+ \to \mathbb{R}_+ \) is a continuous differentiable function with the derivative \( K'(s) \geq 0 \) and \( K(s) > 0 \) for any \( s > 0 \) and
\[
\int_0^\varepsilon \frac{ds}{K(s)} < \infty, \quad \forall \varepsilon > 0, \quad (9)
\]
then the trivial solution of (1) is stochastically finite-time stable, and stochastic settling time satisfies
\[
\mathbb{E}\tau_{x_0} \leq \frac{1}{c} \int_0^{V(x_0)} \frac{ds}{K(s)}. \quad (10)
\]

**Remark 4:** It is easy to know the following functions have the same properties as \( K \) in Theorem 1:
\[
K_1(s) = s^\gamma, \quad 0 < \gamma < 1, s \geq 0, \\
K_2(s) = s^\gamma + s^\alpha, \quad 0 < \gamma < 1, \alpha \geq 1, s \geq 0.
\]

Before giving the proof of Theorem 1, we need the following lemma.

**Lemma 3:** Let \( (X(t), \mathcal{F}_t; 0 \leq t < \infty) \) be a continuous nonnegative supermartingale and \( \tau = \inf\{t \geq 0; X(t) = 0\} \). If \( P(\tau < \infty) = 1 \), then
\[
X(t + \tau) = 0, \quad \forall t \geq 0, \quad \text{a.s.} \quad (11)
\]

**Proof:** Since \( X(t) \) is continuous, \( \tau = \inf\{t \geq 0; X(t) = 0\} \) is a stopping time. So, for any real constant \( t \geq 0 \), \( t + \tau \) is also a stopping time. By Lemma 2, we have \( X(t + \tau) \in L^1 \), and
\[
\mathbb{E}(X(t + \tau)|\mathcal{F}_\tau) \leq X(\tau), \quad \forall t \geq 0. \quad (12)
\]
Taking expectation on both sides of (12), one gets
\[
\mathbb{E}(X(t + \tau)) \leq \mathbb{E}X(\tau) = 0, \quad \forall t \geq 0, \quad (13)
\]
which together with the nonnegativity of \( X(t) \) leads to
\[
\mathbb{E}(X(t + \tau)) = 0, \quad \forall t \geq 0. \quad (14)
\]
Therefore, this implies that (11) holds, which completes the proof.

Now, we can give the detailed proof of Theorem 1.

**Proof of Theorem 1:** From (7) and Lemma 1, it leads to that for each \( x_0 \in \mathbb{R}^n \), there exists a regular continuous solution \( x(t; x_0) \) to (1). Since \( \mathcal{L}V(x) \leq 0 \) and \( V(x) \geq 0, V_t = V(x(t; x_0)) \) is a nonnegative continuous supermartingale with augmented filtration \( \{\mathcal{F}_t\}_{t \geq 0} \) satisfying the usual conditions.

Since \( V \) is positive definite and radially unbounded, from [8], there exists a \( \mathcal{K}_\infty \) class function \( \mu \) such that
\[
\mu(|x|) \leq V(x). \quad (15)
\]
By a supermartingale inequality ([13], p.13, Theorem 3.6), for any \( r > 0 \) and any natural number \( n \), one has
\[
P \left( \sup_{0 \leq t \leq n} V_t \geq \mu(r) \right) \leq \frac{\mathbb{E}V_0 + \mathbb{E}V_n}{\mu(r)} \leq \frac{2V(x_0)}{\mu(r)}. \quad (16)
\]
From \( \mu(|x|) \leq V(x) \), it leads to
\[
\left\{ \sup_{0 \leq t \leq n} \mu(|x(t; x_0)|) \geq \mu(r) \right\} \subseteq \left\{ \sup_{0 \leq t \leq n} V_t \geq \mu(r) \right\}. \quad (17)
\]
which with (16) and $\mu$ being $K_\infty$ function implies that
\[
\begin{align*}
P \left( \sup_{0 \leq t \leq n} |x(t; x_0)| \geq r \right) \\
= P \left( \sup_{0 \leq t \leq n} \mu(|x(t; x_0)|) \geq \mu(r) \right) \\
\leq \frac{2V(x_0)}{\mu(r)}.
\end{align*}
\] (18)

By monotonic convergence theorem, we have
\[
\begin{align*}
P \left( \sup_{t \geq 0} |x(t; x_0)| \geq r \right) \\
= \lim_{n \to \infty} P \left( \sup_{0 \leq t \leq n} |x(t; x_0)| \geq r \right) \\
\leq \frac{2V(x_0)}{\mu(r)}.
\end{align*}
\] (19)

So, for any $r > 0$, by the continuity of $V$, one has
\[
\lim_{x_0 \to 0} P \left( \sup_{t \geq 0} |x(t; x_0)| \geq r \right) = 0.
\] (20)

By Remark 3, the stability in probability follows.

We now turn our attention to proving the finite-time attractiveness in probability. Define a positive definite function
\[
F(x) = \int_0^{V(x)} \frac{ds}{K(s)},
\] (21)

which can be verified that it is $C^2$ in $R^n \setminus \{0\}$. For any initial value $x_0 \in R^n \setminus \{0\}$, we define stopping times
\[
\tau_k = \inf \left\{ t \geq 0; |x(t; x_0)| \notin \left( \frac{1}{k}, k \right) \right\},
\] (22)

\[
\tau_{1k} = \inf \left\{ t \geq 0; |x(t; x_0)| \in \left[ 0, \frac{1}{k} \right) \right\},
\] (23)

and
\[
\tau_{2k} = \inf \left\{ t \geq 0; |x(t; x_0)| \in [k, \infty) \right\},
\] (24)

with $\inf \emptyset = \infty$ and nature numbers $k \in \{2, 3, 4, \ldots\}$. It is clear that $\tau_k, \tau_{1k}$ and $\tau_{2k}$ are all increasing stopping time sequences, and $\tau_k = \tau_{1k} \wedge \tau_{2k}$. We now set $\tau_\infty = \lim_{k \to \infty} \tau_k$, and $\tau_{i\infty} = \lim_{k \to \infty} \tau_{ik}$, for $i = 1, 2$. Since the solution $x(t; x_0)$ is regular, $\tau_2 = \infty$ a.s., and for $r = \tau_1 a.s.$.

The function $F(x)$ is twice continuously differentiable in the domain $\frac{1}{k} < |x| < k$ for any $k$. Applying Itô’s formula in this domain, we get
\[
\begin{align*}
F(x(t \wedge \tau_k; x_0)) &= F(x_0) + \int_0^{t \wedge \tau_k} \mathcal{L}F(x(s; x_0))ds \\
&\quad + \int_0^{t \wedge \tau_k} \frac{1}{K(V)} \partial V \frac{\partial V}{\partial x} g(x(s; x_0))dB(s).
\end{align*}
\] (25)

Noting that $\frac{1}{K(V)} \partial V \partial x g(x)$ is bounded in the domain $\frac{1}{k} < |x| < k$, we have
\[
\int_0^t E \left( \frac{I\{ s \leq \tau_k \}}{K(V)} \left| \frac{\partial V}{\partial x} g(x(s; x_0)) \right|^2 \right) ds < \infty,
\] (26)

where $I\{ \cdot \}$ denotes the indicator function, which together with
\[
\begin{align*}
\mathcal{L}F(x) &= \frac{LV(x)}{K(V)} - \frac{C'(V(x))}{2K^2(V(x))} \left| \frac{\partial V}{\partial x} g(x) \right|^2.
\end{align*}
\] (29)

By condition (8), it is obvious that in this domain $\mathcal{L}F(x) \leq -c$, which together with (28) and $F \geq 0$ leads to $E(t \wedge \tau_k) \leq \frac{F(x_0)}{c}$. Letting $t, k \to \infty$, using Fatou lemma and $\tau_\infty = \tau_1 a.s.,$ one has
\[
E \tau_\infty = E \tau_{1\infty} \leq \frac{F(x_0)}{c}.
\] (30)

It is clear that the first hitting time $\tau_{x_0} = \inf \{ t \geq 0 : x(t; x_0) = 0 \}$ is $\lim_{k \to \infty} \tau_{ik} = \tau_{1\infty} a.s.$ Therefore,
\[
E \tau_{x_0} \leq \frac{F(x_0)}{c} = \frac{1}{c} \int_0^{V(x_0)} \frac{ds}{K(s)} < \infty,
\] (31)
which implies that $P(\tau_{x_0} < \infty) = 1$.

Recalling that $V_t = V(x(t; x_0))$ is a continuous nonnegative supermartingale, using $V_{\tau_{x_0}} = V(x(\tau_{x_0}; x_0)) = 0$ and Lemma 3, we have

$$V_{t+\tau_{x_0}} = 0, \forall t \geq 0, \text{ a.s.} \quad (32)$$

From $\mu(|x|) \leq V(x)$, it follows that $x(t+\tau_{x_0}; x_0) = 0$ a.s., for any $t \geq 0$. Here we complete the proof.

**Remark 5:** Following the same proof process above, we can see that Theorem 1 still holds for nonautonomous stochastic nonlinear systems

$$dx = f(t, x)dt + g(t, x)dB(t) \quad (33)$$

with an additional assumption that system (33) admits a regular continuous solution (either in the strong sense or in the weak sense) for any initial state $x_0 \in \mathbb{R}^n$.

**Remark 6:** If system (1) degenerates into a deterministic system, i.e., the diffusion dynamic $g(x) = 0$ in (1), the condition (8) turns into

$$\dot{V}(x) \leq -cK(V(x)), \forall x \in \mathbb{R}^n \setminus \{0\}, \quad (34)$$

and Theorem 1 then reduced to the corresponding Lyapunov theorem of deterministic system for finite-time stability [14].

**Remark 7:** If condition (9) is replaced by $\int_0^\infty \frac{dx}{K(s)} \leq C$, where $C$ is a positive constant, then the stochastic settling time $\tau_{x_0}$ satisfies $E\tau_{x_0} \leq C/c$, and its upper bound is independent of the initial state $x_0$. Such a function can be chosen as $K(s) = s^\gamma + s^\alpha$ with $0 < \gamma < 1$ and $\alpha > 1$.

### 4 Comparisons with the existing results

Let us first recall the existing results on the stochastic finite-time stability [18,19], and take the classical result in [18] as a theorem.

**Theorem 2** [18]: For system (1), If there exists a $C^2$ function $V : \mathbb{R}^n \to \mathbb{R}_+$, $K_\infty$ class functions $\mu_1$ and $\mu_2$, positive real numbers $c > 0$ and $0 < \gamma < 1$, such that for all $x \in \mathbb{R}^n$,

$$\mu_1(|x|) \leq V(x) \leq \mu_2(|x|), \quad (35)$$

$$LV(x) \leq -cV(x)^\gamma, \quad (36)$$

then the trivial solution of (1) is stochastically finite-time stable.

To see the important contributions of this paper, let us first state a useful corollary that follows from Theorem 1 directly.

**Corollary 1:** For system (1), if there exists a $C^2$ positive definite and radially unbounded function $V : \mathbb{R}^n \to \mathbb{R}_+$, a positive constant $c > 0$, such that

$$LV(x) \leq 0, \forall x \in \mathbb{R}^n, \quad (37)$$

and

$$V \cdot (cV^\gamma + LV) \leq \frac{\gamma}{2} \left| \frac{\partial V}{\partial x} \right|^2, \forall x \in \mathbb{R}^n \setminus \{0\}, \quad (38)$$

where $0 < \gamma < 1$ and the argument $x$ is omitted here without ambiguity, then the trivial solution of (1) is stochastically finite-time stable, and stochastic settling time satisfies

$$E\tau_{x_0} \leq \frac{1}{c(1-\gamma)}(V(x_0))^{1-\gamma}.$$  

**Proof:** Letting $K(s) = s^\gamma, 0 < \gamma < 1$, in Theorem 1, we have Corollary 1 directly.

Let us explain the significant features of this corollary from the following two aspects.

(I) In the classical Theorem 2, $LV$ is required to be not only negative definite, but also not greater than a kind of functions $-cV^\gamma$ with $0 < \gamma < 1$. As far as we know, there is not a paper so far that shows whether the stochastic finite-time stability holds or not if this condition does not hold, but our Corollary 1 gives a positive answer. In fact, we see from condition (38) that $LV$ may be not negative definite somewhere (see the examples below for an explicit support) but yet the corollary shows that the system may still be stochastically finite-time stable.

(II) We see clearly that if (36) is satisfied, (38) must be satisfied but not conversely. It is the term $\left| \frac{\partial V}{\partial x} \right|^2$ that makes condition (38) be satisfied much more easily than condition (36). So Corollary 1 has already enabled us to construct Lyapunov functions more easily in applications. Note furthermore that the term $\left| \frac{\partial V}{\partial x} \right|^2$ is connected with the diffusion coefficient $g(x)$, so our result reveals the important role of white-noise in finite-time stabilizing a stochastic system.

**Example 1:** Consider a one-dimensional stochastic nonlinear system in the form

$$dx = f(x)dt + g(x)dB(t), \quad x_0 \neq 0, \quad (40)$$

where

$$f(x) = -c_1x^p - c_2x^{\beta_1}; \quad c_1 \geq 0, \quad c_2 > 0, \quad 1 > \beta_1 = \frac{p+1}{q+1},$$

$$g(x) = c_3x^{\beta_2}; \quad c_3 \neq 0, \quad 1 > \beta_2 > \frac{1}{2}. \quad (41)$$
and $p$, $p_1$ and $q_1$ are positive odd numbers. Consider a $C^2$ Lyapunov function $V(x) = |x|^\alpha$ with $\alpha \geq 2$. It is not hard to compute

$$L V(x) = -c_1 \alpha |x|^\alpha \rho - c_2 \alpha |x|^\alpha \beta (1 - \alpha) + \frac{1}{2} c_3 \alpha (1 - \alpha) |x|^\alpha \beta (1 - \alpha) - 2 \beta c_1 \alpha |x|^\alpha \beta (1 - \alpha) + \frac{1}{2} c_3 (1 - \alpha) |x|^\alpha \beta (1 - \alpha).$$

(42)

Let us analyze this example from three concrete cases.

**Case 1.** If the parameters satisfy $c_1 = 0$, $2\beta_2 = \beta_1 + 1$ and $c_2 = \frac{1}{2} (\alpha - 1) c_3^2$, we have

$$L V(x) = L |x|^\alpha = 0.$$  

(43)

Meanwhile, it is not hard to verify that the condition (38) is satisfied with $\gamma = \frac{a + 2b}{a}$ and $c \leq \frac{1}{2} \gamma c_3^2 \alpha^2$. Clearly $0 < \gamma < 1$, and hence, the system (40) in this case is still stochastically finite-time stable by Corollary 1 even though $L V(x) = 0$.

**Case 2.** If the parameters satisfy $c_1 > 0$, $p = 1$, $2\beta_2 = \beta_1 + 1$ and $c_2 = \frac{1}{2} (\alpha - 1) c_3^2$; we have

$$L V(x) = -c_1 \alpha V(x) = -c_0 V(x).$$

The condition (38) is also satisfied with $\gamma = \frac{a + 2b}{a}$ and $c \leq \frac{1}{2} \gamma c_3^2 \alpha^2$. Hence, the system (40) in this case is still stochastically finite-time stable by Corollary 1 even though $L V(x) = -c_0 V(x)$.

**Case 3.** If the parameters satisfy $c_1 > 0$, $p = 3$, $2\beta_2 = \beta_1 + 1$, $c_2 = \frac{1}{2} (\alpha - 1) c_3^2$ and $\alpha = 2$, we have

$$L V(x) = L |x|^2 = -2c_1 (V(x))^2.$$  

(45)

The condition (38) is also satisfied with $\gamma = \frac{a + 2b}{a}$ and $c \leq \frac{1}{2} \gamma c_3^2 \alpha^2$. Hence, the system (40) in this case is still stochastically finite-time stable by Corollary 1 even though $L V(x) = -2c_1 (V(x))^2$.

**Example 2:** Let us consider a 2-dimensional stochastic nonlinear system of the form

$$dx_1 = f_1(x_1, x_2) dt + g_1(x_1, x_2) dB_1(t),$$

$$dx_2 = f_2(x_1, x_2) dt + g_2(x_1, x_2) dB_2(t),$$

(46)

where $B_1(t)$ and $B_2(t)$ are two mutually independent Brownian motions, and the coefficients are expressed as

$$f_1(x) = -\frac{1}{8} x_1 + x_2, \quad g_1(x) = \frac{1}{2} \text{sign}(x_1)|x_1|^\frac{3}{2},$$

$$f_2(x) = -x_1 - \frac{1}{8} x_2, \quad g_2(x) = \frac{1}{2} \text{sign}(x_2)|x_2|^\frac{3}{2}.$$  

(47)

By using a Lyapunov function $V(x) = x_1^2 + x_2^2$, it is easy to verify that

$$L V(x) = 2x_1 \cdot f_1 + 2x_2 \cdot f_2 + g_1^2 + g_2^2 = 0.$$  

(48)

However, we can verify condition (38) is satisfied with $\gamma = \frac{2}{3}$ and $c \leq \frac{2}{3}$. In fact, using an elementary inequality in ([5], Lemma 2.3), that is,

$$(a^2 + b^2)^{\frac{1}{2}} \leq |a|^{1+\gamma} + |b|^{1+\gamma}, \quad 0 < \gamma < 1,$$

(49)

we have condition (38) holds, i.e., the following inequality holds

$$c(x_1^2 + x_2^2)^{1+\gamma} \leq \frac{2}{3} (|x_1|^{1+2/3} + |x_2|^{1+2/3})^2,$$

(50)

with $\gamma = \frac{2}{3}$ and $c \leq \frac{2}{3}$. So by Corollary 1, system (46) is stochastically finite-time stable even though $L V(x) = 0$.

**Remark 8:** Examples 1 and 2 give an explicit illustration about the significant features of Corollary 1 or Theorem 1, and show that stochastic nonlinear system may still be finite-time stable even though $L V = 0$ or $L V = -c_0 V^\gamma$ with $c_0 > 0$ and $\gamma \geq 1$. In addition, from the Case 2 of Example 1, we can see that Eq.(4.3) in [18] seems to be a necessary condition on stochastic finite-time instability theorem.

## 5 Multiple Lyapunov functions-based criteria of stochastic finite-time stability

In this section, we shall develop Theorem 1 by the use of multiple Lyapunov functions, and obtain the following stochastic finite-time stability criteria.

**Theorem 3:** For system (1), suppose that there exists a $C^2$ positive definite and radially unbounded function $U : R^n \rightarrow R_+$ such that

$$L U(x) \leq 0, \forall x \in R^n.$$  

(51)

Furthermore, if there exists a $C^2$ positive definite function $V : R^n \rightarrow R_+$, a positive constant $c > 0$ and a continuous differentiable function $K : R_+ \rightarrow R_+$ as in Theorem 1 such that (8) holds, then the trivial solution of (1) is stochastically finite-time stable, and the stochastic settling time $\tau_{x_0}$ satisfies (10).

**Proof:** The proof is similar to that of Theorem 1, and is omitted here.

Thus we may conclude from the theorem the following corollary similar to Corollary 1.

**Corollary 2:** For system (1), suppose that there exists a $C^2$ positive definite and radially unbounded function $U : R^n \rightarrow R_+$ satisfying (51). Suppose moreover that there exists a $C^2$ positive definite function $V : R^n \rightarrow R_+$, a positive constant $c > 0$, such that (38) holds, then the trivial solution of (1) is stochastically finite-time stable, and the stochastic settling time $\tau_{x_0}$ satisfies (39).
Remark 9: The advantage of using multiple Lyapunov functions is that the constraint about $\mathcal{L}V \leq 0$ as in Theorem 1, even though in the case of $\mathcal{L}V > 0$ (i.e., $\mathcal{L}V$ is a positive definite function) the condition (38) maybe still valid. The example below states this point.

Example 3: Consider the one-dimensional stochastic nonlinear system,

$$dx = -\frac{1}{2}c_2x^\beta dt + c_0x^{p+q} dB(t), \quad x_0 \neq 0,$$

where $p < q$ are positive odd numbers, $c_0 \neq 0$. Choosing a $C^2$ Lyapunov function $U(x) = x^2$, one knows that $\mathcal{L}U(x) = 0$. For any $C^2$ Lyapunov function $V(x) = |x|^\alpha$ with $\alpha > 2$, it is not hard to verify that

$$\mathcal{L}V(x) = \frac{1}{2}c_0^2(\alpha^2 - 2\alpha)|x|^{\alpha + \frac{p}{q} - 1} > 0,$$

i.e., $\mathcal{L}V$ is positive definite. However, for Lyapunov function $V(x) = |x|^\alpha$, one can verify that condition (38) is satisfied with $\gamma = 1 - \frac{q-p}{q}$ and $c \leq \frac{q+p}{2q}c_0^2$, clearly $0 < \gamma < 1$. So, system (52) is stochastically finite-time stable by Corollary 2.

6 Simulation examples

In this section, we consider Examples 1-3 again, and give their simulation results to illustrate the theory analysis.

For three cases of Example 1, the initial condition is set to be $x(0) = 1.2$. In Case 1, we choose parameters $c_1 = 0$, $\beta_1 = \frac{1}{3}$, $\beta_2 = \frac{\beta_1+1}{2} = \frac{2}{3}$, $c_2 = \frac{1}{2}$, $c_3 = 1$ and $\alpha = 2$. In Case 2, we choose parameters $c_1 = 1$, $p = 1$, $\beta_1 = \frac{1}{3}$, $\beta_2 = \frac{\beta_1+1}{2} = \frac{2}{3}$, $c_2 = \frac{1}{2}$, $c_3 = 1$ and $\alpha = 2$. In Case 3, we choose parameters $c_1 = 1$, $p = 3$, $\beta_1 = \frac{1}{3}$, $\beta_2 = \frac{\beta_1+1}{2} = \frac{2}{3}$, $c_2 = \frac{1}{2}$, $c_3 = 1$ and $\alpha = 2$. Fig.1 shows the corresponding simulation results. Fig.2 gives the simulation result of Example 2 with initial conditions $x_1(0) = 1.5$, $x_2(0) = 5$, and Fig.3 shows the simulation result of Example 3 with concrete parameters $c_0 = 1$, $p = 3$ and $q = 5$, where the initial condition is set to be $x(0) = 2$.

The simulation results clearly show that the trajectories of the corresponding stochastic systems converge rapidly to the equilibrium state in finite time for any given initial values, and verify the effectiveness of theoretical results.

7 Conclusion

In this paper, some new Lyapunov criteria of stochastic finite-time stability are given. Compared with the existing results about stochastic finite-time stability, these new Lyapunov criteria not only relax the constraint on the infinitesimal generator $\mathcal{L}V$, but also reveal the important role of white-noise in finite-time stabilizing the system. Some examples are constructed to show that
these new Lyapunov criteria enable us to construct Lyapunov functions more easily in applications.
