Abstract—Malotilate was orally administered to rats at a dose of 100 mg/kg 2 hr after partial hepatectomy. Mitochondrial state 3 respiration of the liver increased significantly from 23.4 nmol/min/mg protein in the control rats to 29.3 nmol/min/mg protein in the rats administered with malotilate at 3 hr after the hepatectomy (1 hr after the administration). The administration also resulted in higher tendencies in the respiratory control ratio after 3, 6 or 20 hr (1, 4 or 18 hr after the administration) than in the control rats. Although partial hepatectomy made hepatic ATP concentration remarkably low, it gradually increased (from 1.53 μmol/g liver after 3 hr) to a level of 2.03 μmol/g liver after 20 hr in the rats administered with malotilate. No increase in ATP concentration was observed in the control rats. Correspondingly, the adenylate energy charge also showed higher tendencies in the malotilate administered rats. From these results, it is supposed that malotilate activates the mitochondrial functions which results in increases of ATP concentration and adenylate energy charge. These changes in energy metabolism can be associated with accelerated regeneration of the liver by malotilate.

Materials and Methods

Chemicals, animals and partial hepatectomy: Chemicals and animals used in this experiment, the procedures for partial or sham hepatectomy, and the administration of malotilate and/or its vehicle were the same as those described in our previous paper (6).

Analysis of mitochondrial functions: Liver mitochondrial functions were measured 3, 6 or 20 hr after the partial or sham hepatectomy (1, 4 or 18 hr after the administration). Rat liver mitochondria was prepared by homogenization of rat liver followed by differential centrifugation as described by Hogeboom et al. (11) with minor modifications. The mitochondrial pellet was washed once, suspended in the medium containing 0.25 M sucrose, 0.1% bovine serum albumin and 3 mM Tris-HCl buffer (pH
7.4). The obtained mitochondrial fraction (0.2 ml) was added into the reaction medium (3 ml) containing 0.25 M sucrose, 0.1% bovine serum albumin and 10 mM potassium phosphate buffer (pH 7.4). Six μmol of succinate and 0.25 μmol of ADP were then added. Mitochondrial state 3 respiration, respiratory control ratio (RCR) and ADP/O (P/O) ratio were measured with an oxygen monitor (Rank Brother Co., Ltd., England). Mitochondrial protein was measured according to the method of Lowry et al. (12).

Analysis of adenine nucleotides: Liver adenine nucleotide concentrations and adenylate energy charge were measured at 3, 6 or 20 hr after the partial hepatectomy (1, 4 or 18 hr after the administration). Under ether anesthesia, the liver was removed with pre-cooled aluminium clamps, pulverized in liquid nitrogen and homogenized with 0.6 N perchloric acid. After centrifugation (400×g for 10 min at 4°C), the supernatant of the homogenate was neutralized with 0.54 N KOH and diluted with 0.2 M potassium phosphate buffer (pH 7.0). Adenine nucleotide concentrations were then measured with HPLC (Column: TSK-gel DEAE-2SW, Detector: SPD-2A, Pump: LC-30). Adenylate energy charge was calculated according to the equation proposed by Atkinson (13).

Statistical analysis: The significance of the difference between two groups was assessed by Student’s t-test.

Results

Mitochondrial functions in liver: The state 3 respiration, RCR and P/O ratio of the mitochondrial fraction in the liver of partially or sham hepatectomized rats are summarized in Fig. 1. The P/O ratio was around 2.0 in all the groups. The state 3 respiration at 6 hr after and the RCR at 3 or 6 hr after the hepatectomy showed a tendency to be higher in the sham operated rats administered with malotilate than in the control rats. Therefore, malotilate seems to activate hepatic mitochondrial functions in the sham operated rats. The effect of malotilate was more obvious in the partially hepatectomized rats than in the sham operated rats. The state 3 respiration of the liver mitochondrial fraction significantly increased from 23.4 nmol/min/mg protein in the control to 29.4 nmol/min/mg protein in the malotilate administered group with partial hepatectomy after 3 hr. The RCR in the partially hepatectomized rats tended to be increased after 3 or 6 hr, and it was significantly increased after 20 hr by the administration of malotilate. The P/O ratio in the partially hepatectomized rats also tended to be increased by the administration after 6 or 20 hr.

Adenine nucleotide concentrations in liver: Liver adenine nucleotide concentrations and adenylate energy charge in the partially or sham hepatectomized rats are summarized in Table 1. In the partially hepatectomized rats, liver AMP concentration tended to be higher, but ATP concentration and adenylate energy charge were lower than those in the sham operated rats throughout the experiment. By the administration of malotilate to the partially hepatectomized rats, the AMP concentration was observed to become lower (0.49, 0.54 or 0.62 μmol/g liver in the control and 0.40, 0.34 or 0.45 μmol/g liver in the malotilate administered group at 3, 6 or 20 hr after the hepatectomy, respectively). Although the ATP concentration in the partially hepatectomized control rats remained almost unchanged (1.63, 1.77 or 1.40 μmol/g liver at 3, 6 or 20 hr, respectively), malotilate administration increased it (2.03 μmol/g liver after 20 hr) finally to a level similar to that of sham operated rats. The adenylate energy charge also remained lower after 3 hr in the malotilate administered group, but it then recovered to the same level as that in the sham operated rats 6 or 20 hr after the hepatectomy. Thus, these data show that malotilate elevates ATP concentration and adenylate energy charge in the partially hepatectomized rats.

Discussion

Malotilate has recently been shown to accelerate liver regeneration in rats (6). The present study, where the experimental conditions were similar to those described in our previous study (6), revealed that mitochondrial functions, ATP concentration and adenylate energy charge in the liver of partially hepatectomized rats tended to be
elevated or were significantly elevated by malotilate administration at 3–20 hr after the hepatectomy (Fig. 1 and Table 1). Therefore, the elevation of liver ATP concentration and adenylic energy charge seems to be due to the activation of mitochondrial functions by malotilate. The action of malotilate is considered to contribute to the acceleration of liver regeneration and such an acceleration has already been observed 24 hr after the hepatectomy (6). As reported by Kamiyama et al. (14), the mitochondrial phosphorylative activity increases adaptively to provide energy for enhanced biosynthetic ATP-utilizing reactions at an early stage in the regenerating process of the liver. The present study suggested that malotilate available to hepatocytes makes mitochondria activate providing more energy for the regenerating process.
Table 1. Liver adenine nucleotide concentrations and adenylate energy charge in the partially or sham hepatectomized rats after malotilate administration

| Hours after sham or partial hepatectomy | Hepatectomy | Malotilate | AMP (µmol/g liver) | ADP (µmol/g liver) | ATP (µmol/g liver) | TANa | AECb |

a TAN stands for total adenine nucleotides. b AEC stands for adenylate energy charge. Each value represents the mean±standard error of 5 animals. Significant difference from sham hepatectomized rats, *P<0.05 and **P<0.01. Significant difference from partial hepatectomized rats, +P<0.05 and ++P<0.01. Malotilate or its vehicle was administered 2 hr after sham or partial hepatectomy.
